

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

### Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

### About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. # THE LANCET.

Vol. I.]

LONDON, SATURDAY, SEPTEMBER 25.

[1830-31.

## ADDRESS.

IN addressing a few prefatory remarks to the readers of *THE LANCET*, on commencing the Volumes for another medical year, it is not necessary that we should enlarge upon the subjects which are usually embraced in such essays. Instead of launching into bombastic promises for the future, we have rather to direct attention to the past; and, instead of appearing before the profession as untried men, we stand forward as Journalists who have waged a constant war against the unprincipled abettors of public abuses. In our first address to the profession, we took the opportunity of briefly descanting upon the advantages which must arise to the community from the publication of the lectures that were delivered, and of the cases that were treated, in our great national Hospitals. The success—the extraordinary, the unparalleled success—of *THE LANCET*, shows that our opinions on this question were founded upon a knowledge of the wants of the profession in a particular branch of medical information,—of the true theory of medical science,—and of the best interests of the public. Next to life itself, nothing can be so valuable to man as health, and to this nothing can be so conducive as the ardent cultivation of the science of medicine. Having at an early period observed the vast sources of knowledge which were hidden from public view within the walls of our national institutions, we thought that the press might become available for rendering to practitioners in the most distant parts of the globe, some portion of the practical experience which, for so many succeeding ages, had been enjoyed only by the favoured few;—by individuals who had ever appeared more anxious to embitter or destroy the cup of knowledge, than to pass it with a friendly and cheerful hand around the circle of thirsty inquirers who, had they been permitted, would have diffused its benign influence, like the dew-drops of heaven, over all mankind.

The Lectures and Cases of our public hospitals, we always regarded as the two great sources of medical information, and it was to the publication of these that, from the first, we directed our most especial attention. If the Lectures were sound in principle,—drawn from practical knowledge, and enriched by the ever-sure results of experience,—it is evident that their diffusion amongst practitioners, and especially amongst the junior members of the profession in all parts of the globe, could not fail to produce universal good. On the other hand, if the Lectures were unsound in principle, deficient in practical knowledge, devoid of facts derived from the personal experience of the Lecturer,—we considered that publicity would prove the best corrective; that by this salutary and effectual check, the pupils would be spared the pain, labour,

and expense, of listening to doctrines that were worthless, or even fallacious, and that the public would be protected against the evils which, it is feared, have but too frequently arisen from the propagation of crude, ill-digested, and dangerous medical theories.

In selecting Lectures, therefore, for publication in the pages of this Journal, it must not be inferred that the *excellence* of the discourses has always been to us the magnet of attraction. THE LANCET is a medical newspaper, and we should no more think of publishing *some* Lectures with a view, by their direct application, to improve the practice of medicine, than a daily Journalist would think of improving, immediately and directly, the morals of the people, by publishing an account of a murder, or of a burglary. An advantage of exactly the same kind and extent, is probably derived from publicity in both instances; but the benefit is obtained, in each case, by causes of a directly opposite character. Numerous are the courses of Lectures which we have published during the seven years this Journal has been established, and numerous are the pages that might have been better occupied, as far as instruction was concerned, had not exposure been deemed the most effectual means of leading to the reformation of pernicious principles and practices.

It will readily be confessed, and believed, that it would be a work of supererogation to publish any more Lectures, with a view merely to show that some of the best that ever were written, and many of the worst that ever were written, are annually delivered in this metropolis. These facts being now well known and acknowledged, one of the first objects of publicity has been fully attained. Students, in the present day, *inquire* before they enter to the classes; they are no longer misled, no longer cajoled by false, hypocritical, clap-trap advertisements. Having, therefore, presented the profession with lectures on Surgery, on the Practice of Medicine, on Chemistry, on Pathology, on Midwifery, on Anatomy, on Physiology, on Phrenology, on the Intellectual Composition of Man, on Ophthalmic Surgery, and on the Diseases of the Nervous System, with a great number of clinical lectures on desultory diseases, there remain only three or four other courses mentioned in the curricula of our profound medical colleges. The publication of these lectures we must defer to a future occasion; for, in consequence of the great and unexpected length of the course which we have just concluded, we have been compelled to omit in the volumes for the past year, nearly the whole of the customary reports from our Hospitals,—a species of medical information far, very far, surpassing, in point of real value, every other description of medical record; while the clinical lectures, which are founded on the cases, are often instructive in the highest degree, and are incomparably superior to the sing-song trash which is annually doled out at so much a yard, under the title of “regular courses.” Of “regular courses” of lectures, then, for the present, we take our leave; and it will be our object, in succeeding Numbers, to render THE LANCET a moving picture of every interesting fact that may present itself to the notice of our reporters in the great national establishments. It is too true, that the students of this metropolis are but seldom gratified by the delivery of a clinical lecture,—an omission on the part of the medical officers of our Hospitals which cannot be too severely reprobated. We believe that Dr. ELLIOTSON, of St. Thomas’s Hospital, Dr. WATSON and Mr. CHARLES BELL, of the Middlesex, Mr. BRODIE, of St. George’s, and Mr. EARLE, of St. Bartholomew’s, are the only physicians and surgeons who *regularly* deliver clinical lectures in their respective institutions.

In order to remedy a defect of this magnitude, the pupils should obtain a promise

before paying their entrance fees, that the physicians and surgeons would regularly deliver clinical lectures upon all diseases of importance that may fall under their treatment. The value, indeed we may say the very great value, of the clinical discourses, which were published in the Volumes of *THE LANCET* just concluded, is enough to render every student extremely anxious for this species of medical disquisition. The data were before his eyes, the treatment has just been under his immediate notice, he has seen the effects of the remedies, and, therefore, he has had the best opportunity of judging for himself of the propriety and soundness of the conclusions of his preceptor. By the sufferings of the patient, the observer becomes sympathetically interested in his welfare, and impressions painfully produced are long fixed upon the memory. The eye is evidently the great channel that leads to medical knowledge: this may at any time be proved by contrasting the dubious and obscure descriptions of disease given by the theorist, with the positive, distinct, and picturesque language of the actual observer. Abstract theories, tedious, wearisome, uninteresting lectures of an hour and a half in duration, neither aided nor illustrated by the presence of disease itself, are almost useless to the tyro, and to the experienced practitioner present little more than old, well-known maxims, obscured by the sophistry of unsubstantial speculation. Accurate descriptions of diseases, then, as they really occur in our hospitals, together with the expositions given by the teacher, furnish materials for supplying a knowledge of the principles and practice of medicine inferior only to those which can be derived from personal observation and experience. It was under this impression that we commenced the publication of hospital reports in the autumn of 1823, and since that time the voice of the profession has every-where been raised in favour of the plan, all acknowledging that it has been of incalculable service to science and to the cause of medical reform. A kind of medical police has been thus established, having a constant tendency to ensure to the student, punctuality from the lecturer; to the teacher, respect and attention from the pupil; and to the patient, a safe, diligent, and humane treatment from his medical attendant. At the same time, the practice and experience furnished by our great medical institutions are, when worthy of imitation, rendered available to those practitioners who reside at a distance from the metropolis. Actuated by a strong feeling on all these points, it may readily be conceived that we have not curtailed the hospital reports in our preceding volumes without very deep regret; and the resumption of operations, with our little regiment of pioneers, in this field of inquiry, and, alas! sometimes of slaughter, will be a source of satisfaction to ourselves, and must prove of infinite advantage to all classes of the community.

In publishing "regular courses" of lectures, upon the practice of medicine or surgery for example,—it must be confessed, that after such a number has been presented to the public, and while there are so many systematic works on these hacknied subjects, not one page in forty can consist of new matter; besides, if a surgeon or physician make a discovery of the least importance in medical science, he hesitates not to lay it before the profession in the shape of a well-bound, hot-pressed octavo. Thus secure, by the natural vanity of all authors, against the concealment of important facts, or valuable opinions,—*THE LANCET*, on entering its eighth year, presumes to think that it can go alone; that it can proceed unaided even by the ornamental cords which have been so frequently and so ingeniously woven from the mutilated folios of certain dictionaries and encyclopædias. Instead of leading-strings, instead of guides, they have acted like fetters, and the limbs have grown restless and painful under the weight and pressure

of restraint. The go-cart, that yields assistance to the infant, would act as a disagreeable clog to the boy who is desirous of stretching himself vigorously in the seventh year of his age; and even the infant, with the support of his perambulating machine, would be ill-requited in his search after nutriment, if he could only discover one grain of wheat in a bushel of chaff.

The discontinuance for the present, then, of the "regular courses" of lectures, besides affording space for the insertion of many Hospital reports, will enable us also to devote more attention to the reviews of new works. We shall be enabled, likewise, to appropriate a larger space to the contributions of many well-informed and scientific correspondents; the important proceedings also of several learned societies, accounts of which we have hitherto been frequently compelled to omit, will in future receive constant and earnest attention. In a word, it shall be our endeavour to render *THE LANCET* an epitome of every-thing that is passing in the medical world—a faithful picture of "medical life."

Of the more prominent events which have been connected with the profession during the past year, two or three only call for notice in this place.

The decision of Lord Tenterden, in the cause of *Handey v. Henson*, is the commencement of a new era in the practice of medicine; it has unmasked pretenders, and reduced them to their proper grade, while to the scientific services of the well-qualified and regular practitioner it affords a just security, and has raised him to his proper, honourable rank in the profession.

The self-perpetuating, tyrannical council of the college of surgeons still labours in its sordid vocation. Several more of the MEMBERS of the college have been recently degraded by it, and are for ever deprived of the least chance of assuming the robes of office. Their names have been passed over in the list, they have been rejected without open discussion, and punished without an opportunity of meeting their accusers, either by themselves or their agents, or of knowing of what they have been accused. The CHARTER of this college is a nuisance that *must* be abated.

The circumstances connected with the inquest held on the body of the late Miss Catherine CASHIN might well be adverted to at some length in this place, were not the affair still *sub judice*, and did not impartial justice demand that nothing should be advanced, which by possibility could influence the minds of the jury, before whom the fortunes, the reputation, and even the life of a fellow-creature, may be at stake.

By reminding our readers, in conclusion, of the manner in which we have repeatedly exposed the ignorance and incompetency of non-medical coroners, we embrace this opportunity of pointing to the late contest for the office of coroner for this county, as one of the most splendid triumphs ever achieved for the press and the medical profession. It exhibits a brilliant example of what reason can accomplish over prejudice. There is not now to be found in the county of Middlesex a single well-informed mechanic who would endeavour, by his vote, to place an attorney in the office of coroner. Every man acknowledges, that as it is a medical office, so it can only be adequately occupied by a medical judge. It is evident from what transpired during the struggle, that the long-persecuted members of our incomparable profession have made a rapid march towards intelligence and moral power. Medical men in their canvass, were everywhere received by the public with open arms; and it is no more than an act of justice towards the gentlemen of the law to state, that many of the most intelligent at the Bar were the warm, zealous, and active supporters of the medical candidate. At one period

of the election, there were on the hustings not less than seven gentlemen, from the Inner Temple alone, actively exerting themselves on his behalf. The medical candidate,—although opposed to an unprincipled league of five attorneys, of whom three had advertised that from the number of promises they had obtained they were “confident of success,”—was only in a minority of one hundred and thirty-six on a poll of seven thousand two hundred and four; the attorney had not a hand raised in his favour before the hustings, while from forty to fifty thousand were exhibited in acknowledgment of the claims of the surgeon. With the public, therefore, this may be regarded as a settled question, and never again will the medical profession be insulted by the election of an attorney to the office of medical judge, in the county of Middlesex.

## ACCOUNT OF THE MEDICAL AND SURGICAL SCHOOLS OF LONDON,

*For the Session 1830-31.*

THE following are the Regulations published by the College of Surgeons and Apothecaries Company, which are to be rigidly observed by the students, or they will not be admitted to examination.

### COLLEGE OF SURGEONS.

THE College of Surgeons requires of candidates six years' professional study; to attend not less than three winter courses of anatomy, two courses of dissection, two courses of the principles and practice of surgery (three months each or one six months), two courses of practice of medicine (three months each or one six months), one course on materia medica and botany, two courses on chemistry (of three months each), and two courses on midwifery (of three months each); hospital surgical practice, twelve months, or during four years the surgical practice of a recognised provincial hospital, and six months at least of a London Hospital.

### APOTHECARIES COMPANY.

REGULATIONS TO BE OBSERVED BY STUDENTS, WHOSE ATTENDANCE ON LECTURES SHALL COMMENCE ON OR AFTER THE FIRST OF JANUARY, 1831.

STUDENTS who are at present pursuing their medical studies, and those who may begin to attend lectures at the commencement of the next medical session (viz. October), will be received as candidates for examination by complying with the regulations heretofore published.

Every candidate for a certificate to practise as an apothecary, will be required to produce testimonials of having served an apprenticeship of not less than five years to an apothecary:—The apprenticeship must have been served with a person legally qualified to practise as an apothecary, either by having been in practice prior to or on the 1st of August, 1813, or by having received a certificate of his qualification from the Court of Examiners.

Of having attained the full age of twenty-one years:—As evidence of age, a copy of the baptismal register will be required in every case where it can possibly be procured.

Of good moral conduct:—A testimonial of moral character from the gentleman to whom the candidate has been an apprentice, will always be more satisfactory than from any other person.

Of having devoted at least two years to an attendance on lectures and hospital practice,

## REGULATIONS OF THE APOTHECARIES COMPANY.

The candidate must have attended the following courses of lectures. The lectures required in each course respectively, must be given on separate days.

*Chemistry*.—Two courses; each course consisting of not less than forty-five lectures.

*Materia Medica and Therapeutics*.—Two courses; each course consisting of not less than forty-five lectures.

*Anatomy, Physiology, and Anatomical Demonstrations*.—Two courses; of the same extent as required by the Royal College of Surgeons of London.

*Principles and Practice of Medicine*.—Two Courses; each course consisting of not less than forty-five lectures, to be attended subsequently to the termination of the first course of lectures on chemistry, materia medica, and anatomy and physiology.

*Botany*.—One course.

*Midwifery and the Diseases of Women and Children*.—Two courses to be attended during the second year.

*Forensic Medicine*.—One course; to be attended during the second year.

Students are moreover recommended diligently to avail themselves of instruction in morbid anatomy.

The candidate must also have attended for twelve months at least the physician's practice at an hospital containing not less than sixty beds, and where a course of clinical lectures is given; or for fifteen months at an hospital wherein clinical lectures are not given; or for fifteen months at a dispensary connected with some medical school recognised by the court. The whole of such attendance to be subsequent to the first year of attendance on lectures. Certificates of attendance on the physician's practice at dispensaries will continue to be received until the 1st of January, 1833, from all such as have heretofore been admitted, but after that time the present regulation will be strictly adhered to.

The testimonials of attendance on lectures and hospital practice must be given on a printed form, with which students may be supplied, on application at the under-mentioned places:—In London, at the Beadle's Office, at this Hall. In Edinburgh, at Messrs. McLachlan and Stewart's, booksellers. In Dublin, at Messrs. Hodges and Smith's, booksellers. In the provincial towns, where there are medical schools at the hospital, or from the teacher who keeps the register of the school.

Students are enjoined to observe that no other form of testimonial will be received; and that no attendance on lectures will qualify a candidate for examination, unless the teacher is recognised by the court.

The teachers in Dublin, Edinburgh, Glasgow, and Aberdeen, recognised by the constituted medical authorities in those places respectively, are recognised by the court.

*Registration*.—A book is kept at the Hall of the society for the registration at stated times of the names of students, and the lectures, hospitals, or dispensaries, they attend. The book will be opened for the registration of those students whom these regulations affect, on the 1st of February, 1831.

All students in London are required to appear personally, and to register the several classes for which they have taken tickets; and those only will be considered to have complied with the regulations of the court, whose names and classes in the register correspond with the testimonials of the teachers.

The book will be open for the registration during the first twenty-one days of the months of February, June, and October, from nine o'clock until two.

The court also require students at the provincial medical schools to register their names in their own hand-writing, and the classes they attend, with one of the teachers in each respective school, within fourteen days from the commencement of each course of lectures, and those students only will be deemed to have complied with the regulations whose names are so registered. The students will be informed at each school, respectively, of the name of the teacher to whose care the register will be confided.

Each student, at his first registration, will receive the printed form on which he is to obtain the certificates of his teachers.

### *The Examination of the Candidate will be as follows:—*

- |  |   |
|--|---|
| <ol style="list-style-type: none"> <li>1. In translating parts of Celsus de Medicina, or Gregory Conspectus Medicinæ Theoreticæ, Pharmacopœia Londinensis, and Physicians' Prescriptions.</li> <li>2. In Chemistry.</li> </ol> | <ol style="list-style-type: none"> <li>3. In Materia Medica and Therapeutics.</li> <li>4. In Botany.</li> <li>5. In Anatomy and Physiology.</li> <li>6. In the Practice of Medicine.</li> </ol> |
|--|---|

*Notice*.—Every person offering himself for examination must give notice in writing to the clerk of the society on or before the Monday previously to the day of examina-

tion, and must also, at the same time, deposit all the required testimonials at the office of the beadle, where attendance is given every day, except Sunday, from nine until two o'clock.

Candidates will be admitted to examination in the order in which their names stand on the notice paper; and those neglecting to attend agreeably to their notice, will, upon a subsequent application, be placed at the bottom of the list.

By the 22d section of the Act of Parliament, no rejected candidate can be re-admitted to be examined until the expiration of six months from his former examination.

The court meet in the Hall every Thursday, where candidates are required to attend at half-past four o'clock.

(By order of the Court)

JOHN WATSON, Secretary.

Apothecaries Hall, Sept. 9, 1830.

### HOSPITALS AND SCHOOLS.

THE following tables, with the notes attached to them, present a list of the various medical and surgical schools open to students in London for the session commencing October 1st—an enumeration of the branches of knowledge which are taught in them—the names of the teachers and professors—the hours of lecture and attendance—and the expense of entering to each course and to the medical and surgical practice of the hospitals and dispensaries;—together with some other particulars which the various teachers have appended to their prospectuses.

### UNIVERSITY OF LONDON.

Classes and Professors.	Days and Hours of Lectures.	Fees to the Courses.*
Anatomy; Professor Pattison.	Daily, except Saturdays, at 2 p.m.	Whole course, 7 <i>l</i> .; or first division 4 <i>l</i> .; second div. 3 <i>l</i> .; perpetual, 10 <i>l</i> .
Ditto; Prof. Bennett.	Daily, except Sat., 11 a.m.	W. C. 6 <i>l</i> .; or 1st D. 3 <i>l</i> .; 2nd D. 3 <i>l</i> .; P. 9 <i>l</i> .
Demonstrations and Dissections; Prof. Bennett and Mr. R. Quain.	.....	
Physiology; Prof. C. Bell.	Tues. and Thur. from 5 to 6.	W. C. 3 <i>l</i> .; P. 4 <i>l</i> . 10 <i>s</i> .
Nature and Treatment of Diseases; Prof. Conolly.	Daily, except Saturday, from 4 to 5.	W. C. 6 <i>l</i> .; or 1st Div. 3 <i>l</i> .; 2nd D. 3 <i>l</i> .; P. 9 <i>l</i> .
Surgery; Prof. Pattison.	Mon. and Fri. from 5 to 6.	W. C. 2 <i>l</i> .; P. 4 <i>l</i> .
Midwifery, and Diseases of Women and Children; Prof. Dr. Davis.	Daily, except Sat. from 9 to 10.	W. C. 5 <i>l</i> .; 1st D. 3 <i>l</i> .; 2nd D. 2 <i>l</i> .; P. 7 <i>l</i> .
Clinical Medicine; Prof. Dr. Watson.	Mon. and Fri. from 12½ to 1½.	W. C. 4 <i>l</i> .; half the C. 2 <i>l</i> .
Materia Medica and Therapeutics; Prof. Dr. Thomson.	Daily, except Sat. from 8 to 9.	W. C. 6 <i>l</i> .; 1st D. 3 <i>l</i> .; 2nd D. 3 <i>l</i> .; P. 9 <i>l</i> .
Chemistry; Prof. Dr. Turner.	Daily, except Sat. from 10 to 11.	W. C. 7 <i>l</i> .; 1st D. 4 <i>l</i> .; 2nd D. 3 <i>l</i> .; P. 10 <i>l</i> .
Compar. Anatomy; Prof. Dr. Grant.	Daily, except Sat. from 3 to 4, to Jan. 1st, 1831.	W. C. 2 <i>l</i> .
Med. Jurisprudence; Prof. Dr. Smith.	Mon. Wed. and Fri. from 7½ to 8½.	Not yet announced.
Botany; Prof. Lindley.	Daily, except Mon. from Oct. 1 for 6 weeks, and from Apr. 1 for 6 weeks.	W. C. 3 <i>l</i> .; P. 6 <i>l</i> .

\* In this column W. C. means, whole course—D. division—and P. perpetual.

*Hospital Attendance at the Middlesex Hospital, Berners Street, Oxford Street.*

Physicians:  
Dr. M<sup>c</sup>Michael,  
Dr. Hawkins,  
Dr. Watson.  
Surgeons:  
Mr. Joberns,  
Mr. Bell,  
Mr. Mayo.

Hospital attendance daily, except Saturday, from half past twelve to half past one.

*Medical Practice.*—Academical session of 9 months, 12l. 12s. Second session, 12l. 12s., after which the pupil will have free admission; or a fee of 21l. at once, or of 9l. 9s. in addition to the first 12l. 12s., if paid before the conclusion of the first session, entitles the pupil to free admission. Entrance fee to the apothecary, 1l. 1s.; to the secretary, 5s.  
*Surgical Practice.*—The same as the above.

*Dispensary Attendance at the Dispensary, No. 4, George Street, Euston Square.*

Attended by Drs. Conolly, Thomson, Davis, and Pattison.

Dispensary attendance daily, except Saturday, from half past twelve to half past one.

For twelve months, 6l. 6s.

*Table of Day and Hours of Attendance for the Pupils forming the Medical Classes.*

	M.	Tu.	W.	Th.	F.	S.	Class.
8 to 9	—	—	—	—	—	—	Materia Medica.
9 .. 10	—	—	—	—	—	—	Midwifery.
10 .. 11	—	—	—	—	—	—	Chemistry.
11 .. 12	—	—	—	—	—	—	Anatomy.
12½ .. 1½	—	—	—	—	—	—	Clinical Medicine.
12½ .. 1½	—	—	—	—	—	—	Hospital Attendance.
12½ .. 1½	—	—	—	—	—	—	Dispensary Attendance.
2 .. 3	—	—	—	—	—	—	Anatomy.
3 .. 4	—	—	—	—	—	—	Comparative Anat., 15 Oct. to 31 Jan.
3 .. 4	—	—	—	—	—	—	Zoology, 1 Feb. to 30 April.
4 .. 5	—	—	—	—	—	—	Nature and Treatment of Diseases.
5 .. 6	—	—	—	—	—	—	Surgery.
5 .. 6½	—	—	—	—	—	—	Physiology.
7 .. 8½	—	—	—	—	—	—	Medical Jurisprudence.
.....	—	—	—	—	—	—	Botany, beginning of October to middle of November, and 1st April to middle of May.

## NOTES ON THE CLASSES.

*Anatomy.* Mr. Pattison and Mr. Bennett are associated in the chair of anatomy. The descriptive anatomy of the bones, ligaments, muscles, arteries, veins, nerves, and lymphatics, and surgical anatomy, will be taught by Professor Pattison. The descriptive anatomy of the viscera, and general anatomy, comprising the development and organization of the several tissues, by Professor Bennett. Two complete courses of anatomy will be delivered during the session. The Museum of anatomy is open to the medical students every day from nine in the morning to dusk.

*Demonstrations and Dissections.* Mr. Bennett will be assisted by Mr. Quain. Weekly examinations will be held, and those pupils only who have regularly at-

tended the examinations will be admitted to contend for honours and medals at the close of the session.

*Physiology.* In this course of lectures, the professor presents the anatomy before the class in a form somewhat different from that in which it is exhibited by the professors of anatomy, in order to secure a sound foundation for reasoning, and to join the knowledge of structure with that of the properties of life in the parts. To comply with the regulations of the College of Surgeons and Society of Apothecaries, the student must attend the lectures of the professor of physiology and those of the professor of anatomy.

*Nature and Treatment of Diseases.* These lectures are illustrated by a large collection of drawings, made from cases exhibiting the various structural changes effected by disease; and also by preparations from the Museum of Anatomy. Whenever it is practicable, recent morbid specimens will be presented to the class. The drawings are placed in frames in the museum after each lecture, for more particular examination; and the preparations are arranged for reference during the whole progress of the course.

*Midwifery, and Diseases of Women and Children.* The subjects to be treated of by the professor of midwifery will be included under three principal departments, viz. anatomical, physiological, and pathological or practical. The two former will treat of the structures and functions of such parts and organs as are more or less immediately concerned in the practice of midwifery. The latter will treat of the actual practice of the art itself. Under this principal division of the course will be given particular instructions for the obstetric and medical treatment of all varieties of labours, under their respective heads of *Natural, Preternatural, Complex, and Instrumental*; as also ample histories of the most important diseases incident to the human female during the several epochs of her life; but most especially those to which she is subject during pregnancy, and in the puerperal state. The last section of the course will treat of the principal ailments of infants during the month, and then successively of eruptive and other diseases of the skin, of the diseases of the alimentary organs, of the morbid phenomena incident to the process of dentition, of convulsions, and of hydrocephalus.

*Clinical Medicine.* With the exception of the introductory lectures, this course is given at the Middlesex Hospital.

*Materia Medica and Therapeutics.* A museum has been formed by the professor of this department for the illustration of his lectures, to which the students of his class have access under certain regulations. Instruction in pharmaceutical chemistry will be given to private pupils in the professor's laboratory, which contains a steam apparatus, and facilities for vegetable analysis.

*Chemistry.* The professor proposes to give a few lectures on mineralogy and geology; but in order that such lectures should not interfere with other arrangements, they will be delivered on Saturdays. They will probably commence in the month of January. During the course of the session, there will be one or more classes of practical chemistry, which will commence towards the close of January.

*Comparative Anatomy.* In this course the organisation of the whole animal kingdom is considered. The varieties presented by the internal organs, and the modifications of their functions, are examined in every class of animals. The lectures and demonstrations are illustrated by recent dissections, by a series of zootomical preparations, and by drawings.

*Medical Jurisprudence.* The arrangements not finally completed.

*Medical Botany.* Commence early in October, and will continue for about six weeks daily, except Mondays; after which there will be a suspension of the lectures till the 1st of April, when they will be resumed for six weeks more. The autumn course will consist of botanical demonstrations, and an explanation of the principles by which the properties and internal organisation of plants are to be judged of by their external characters. The spring course will be occupied in considering the physiology and comparative anatomy of vegetation, and will comprehend the application of these branches of science to agriculture, horticulture, and systematic arrangement. The course of botany is subdivided in this manner, in order to enable the students in the medical school to complete their course of botany along with the medical classes; and to meet the regulations of the Society of Apothecaries, and those under which the University diploma is granted. But it would be to the advantage of students, if they were to extend their attendance to the whole of the spring courses, terminating in the end of June, the particulars of which may be known at the University. Although the second part of the spring course answers nominally to that of the autumn, yet the subjects employed in illustration will be totally different. Payment to the University for the autumn and whole of the spring course, 4l.

*Hospital Attendance.* The students may witness hospital practice at the Middlesex

## ST. BARTHOLOMEW'S HOSPITAL.

Hospital, which is in the vicinity of the University. Dr. Watson and Mr. Bell deliver clinical lectures upon their cases in the hospital.

**Dispensary Attendance.** The medical and surgical patients, and those of the professor of midwifery, are made the subjects of clinical instruction. The method of investigating and of prescribing for diseases is explained and illustrated, and the pupils have opportunities of attending patients at their own houses, and of becoming practically acquainted with the management of cases, under the superintendence of their teachers.

## ST. BARTHOLOMEW'S HOSPITAL.

Classes and Lecturers.	Days and Hours of Lectures.	Fees to the Courses.
Medicine; Dr. Hue.	Tues. Thur. and Sat. at 10 a.m.	One C. 4l. 4s.; Two C. 6l. 6s.; P. 7l. 7s.
Surgery; Mr. Lawrence.	Mon. Wed. and Fri. at 7 p.m.	One C. 5l. 5s.; P. 8l. 8s.
Chemistry; Dr. Hue.	Mon. Wed. and Fri. at 10 a.m.	One C. 4l. 4s.; Two C. 7l. 7s.; P. 8l. 8s.
Materia Medica and Botany; Dr. Hue.	Tues. Wed. and Fri. at 11½ a.m.	One C. 2l. 2s.; Two C. 3l. 3s.; P. 4l. 4s.
Anatomy and Physiology; Mr. Stanley.	Daily at 2½ p.m.	1st C. 5l. 5s.; 2d C. 4l. 4s.; 3d C. 3l. 3s.; P. 10l. 10s.
Clinical Lectures on Surgery; Mr. Earle.	.....	Gratuitous.
Demonstrations and Dissections; Mr. Skey and Mr. Wormald.	Demonstrations daily at 9 a.m.	One C. 3l. 3s.; P. 10l. 10s.
Midwifery, and Diseases of Women and Children; Dr. Conquest.	Tues. Thur. and Sat. at 7 a.m.	One C. 3l. 3s.; Two C. 5l. 5s.; P. 8l. 8s.
Hospital Attendance. — Physicians: Drs. Roberts, Hue, and Latham. — Surgeons: Messrs. Vincent, Lawrence, and Earle.	Hours of attendance extremely irregular.	Physician's pupil, six months, 12l. 12s.; P., 32l. 11s. — Surgeon's pupil, 6 mos., 18l. 18s.; 12 mos., 26l. 5s. — Dresser to the Surgeons 6 mos., 37l. 16s.; 12 mos., 52l. 10s.

**Surgery.** This course is intended to embrace the whole of surgery, medical and operative. The introductory lecture will be delivered on Friday, October 1st, at half past two p.m. The particular subjects will be illustrated clinically, as far as the cases occurring in the hospital during the progress of the course will allow.

**Medicine, Chemistry, Materia Medica, and Botany.** The lectures on medicine commence on Saturday, October 2nd, at ten a.m. Those on chemistry, Monday, October 4th, at ten a.m. The laboratory will be open every Monday, Wednesday, and Friday, from nine o'clock until noon, for the preparation and repetition of the several experiments connected with the subject of the course, and for the general purposes of operative chemistry. Gentlemen entering as perpetual pupils to both lectures on medicine and chemistry, are considered as perpetual also to all the others. Clinical lectures on the cases of patients in the hospital, will be given every Saturday at a quarter past eleven a.m. The course on materia medica and botany commences on Friday, October 8th, at a quarter past eleven a.m.

**Anatomy, &c.** These lectures commence on Saturday, October 2nd, at 2½ p.m.

**Midwifery.** Pupils, when qualified, are supplied with cases of labour gratuitously.

Morbid inspections as opportunities occur, at one o'clock. The museum of the hospital is opened every day for the admission of students.

## ST. THOMAS'S HOSPITAL.

Classes and Lecturers.	Days and Hours of Lectures.	Fees of the Courses.
Medicine; Drs. Elliotson and Williams.	Tues. Thur. and Sat., at 11 A.M.	1st C. 3 <i>l</i> . 3 <i>s</i> .; 2nd C. 2 <i>l</i> . 2 <i>s</i> .; P. 6 <i>l</i> . 6 <i>s</i> .
Materia Medica and Medical Botany; Dr. Roots.	Tues. and Fri. at 4 P.M.	1st C. 3 <i>l</i> . 3 <i>s</i> .; 2nd C. 2 <i>l</i> . 2 <i>s</i> .; P. 4 <i>l</i> . 4 <i>s</i> .
Chemistry; Dr. Burton.	Mon. Wed. and Fri. at 11 A.M.	1st C. 4 <i>l</i> . 4 <i>s</i> .; 2nd C. 2 <i>l</i> . 2 <i>s</i> .; P. 6 <i>l</i> . 6 <i>s</i> .
Midwifery, and Diseases of Women and Children; Drs. Ferguson and Ashburner.	Mon. Wed. and Sat. at 4 P.M.	1st C. 3 <i>l</i> . 3 <i>s</i> .; 2nd C. 2 <i>l</i> . 2 <i>s</i> .; P. 5 <i>l</i> . 5 <i>s</i> .
Surgery; Mr. Green.	Mon. and Wed. at 8 P.M., and after Xmas on Fridays also.	One C. 3 <i>l</i> . 3 <i>s</i> .; P. 5 <i>l</i> . 5 <i>s</i> .
Anatomy, Physiology, and Operations; Mr. Tyrrell and Mr. South.	Daily at 4½ P.M.; Demonstrations by Mr. Solly, daily, at 10 A.M.	Lectures; 1st C. 3 <i>l</i> . 3 <i>s</i> .; 2nd C. 2 <i>l</i> . 2 <i>s</i> .; P. 5 <i>l</i> . 5 <i>s</i> .; Dissections; 1st C. 3 <i>l</i> . 3 <i>s</i> .; 2nd C. 2 <i>l</i> . 2 <i>s</i> .; P. 5 <i>l</i> . 5 <i>s</i> .
Comparative Anatomy; Mr. South.	Thur. at 8 P.M.	One C. 1 <i>l</i> . 1 <i>s</i> .; P. 2 <i>l</i> . 2 <i>s</i> .
Hospital Practice; Physicians, Dr. Elliotson, Dr. Roots, Dr. Burton.	The physicians visit daily at 12. Dr. Elliotson on Tues. and Fri.; Dr. Roots on Wed. and Sat.; Dr. Williams on Mon. and Thur.; Dr. Burton sees the out-patients on Thurs. and Sat. at 11 A.M.	Physician's pupil, 2 yrs. 24 <i>l</i> . 3 <i>s</i> .; 1 year 15 <i>l</i> . 15 <i>s</i> .; 9 months 12 <i>l</i> . 12 <i>s</i> .
Surgeons; Mr. Travers, Mr. Green, Mr. Tyrrell.	The surgeons visit daily at 12. Mr. Travers on Mon. and Thur.; Mr. Green on Tues. and Fri.; Mr. Tyrrell on Wed. and Sat. Out-patients seen on Mon. at 12. Operations on Fri.	Surgeon's pupil, one year, 26 <i>l</i> . 6 <i>s</i> .; 6 months 20 <i>l</i> .; a second entry, if within 2 months, 6 <i>l</i> . 6 <i>s</i> .; dresser 1 year 51 <i>l</i> . 2 <i>s</i> .; 6 months 32 <i>l</i> . 12 <i>s</i> .

*Medicine.* Dr. Elliotson will deliver the first course, and Dr. Williams the second. A clinical lecture every Thurs. at one P.M. to the physician's pupils, by Dr. Elliotson.

*Materia Medica and Botany.* The medical botany forming a part of these lectures, will be delivered by Mr. Iliff, at the conclusion of each course, to which the pupils entering to the materia medica will be privileged to attend.

*Surgical Practice.* Clinical lectures will be given to the dressers and surgeons' pupils. Pupils entering to the surgical practice of St. Thomas's Hospital, are allowed to attend that of Guy's. [Gentlemen who enter to the practice or the lectures at this hospital, are allowed the use of the library and of the reading room, so long as they continue attending as pupils.]

## GUY'S HOSPITAL.

Classes and Lecturers.	Days and Hours of Lectures.	Fees for the Courses.
Medicine; Drs. Bright and Addison.	Mon. Wed. and Fri. at 3½ p.m.	1st C. 4 <i>l</i> . 4 <i>s</i> .; 2nd C. 3 <i>l</i> . 3 <i>s</i> .; 3rd and P. 2 <i>l</i> . 2 <i>s</i> .; P. 8 <i>l</i> . 8 <i>s</i> .
Materia Medica, &c., and Medical Botany; Dr. Addison.	Tues. and Fri. at 7 p.m.	1st C. 3 <i>l</i> . 3 <i>s</i> .; 2nd and P. 2 <i>l</i> . 2 <i>s</i> .; P. 4 <i>l</i> . 4 <i>s</i> .
Midwifery, and Diseases of Women and Children; Dr. Blundell.	Daily, at 8½ a.m.	One C. 3 <i>l</i> . 3 <i>s</i> .; Two C. 5 <i>l</i> . 5 <i>s</i> .; 3rd, 4th, and 5th C. each 2 <i>l</i> . 2 <i>s</i> .; P. 10 <i>l</i> . 10 <i>s</i> .
Physiology; Dr. Blundell.	Mon. and Wed. at 6½ p.m.	One C. 2 <i>l</i> . 2 <i>s</i> .; 2nd C. and P. 2 <i>l</i> . 2 <i>s</i> .; P. 3 <i>l</i> . 3 <i>s</i> .

## GUY'S HOSPITAL—(continued.)

Chemistry; Messrs. Aikin and A. Barry.	Tues. Thur. and Sat. at 10½.	1st C. 4l. 4s.; 2nd C. 3l. 5s.; 3rd, 2l. 2s.; P. 8l. 8s.
Anatomy and Operations; Mr. B. Cooper.	Daily, at 2 p.m.	One C. 5l. 5s.; Two C. 9l. 9s.; Third C. 2l. 2s.; P. 10l. 10s.
Dissections.	.....	Each C. 3l. 3l.; P. 10l. 10s.
Surgery and Operations; Messrs. Key and Morgan.	Tues. Thur. and Fri. at 8 p.m.	One C. 3l. 3s.; P. 5l. 5s.
Natural Philosophy; Mr. A. Barry.	Thur. at 6 p.m.	One C. 2l. 2s.; P. 3l. 3s.; Hospital pupils 1l. 1s. less.
Hospital Practice; Physicians, Drs. Cholmeley, Beck, Bright, and Addison.	Attendance of the most irregular description.	Physician's pupil, 9 mos. 12l. 13s.; 12 mos. 17l. 18s.; P. 24l. 4s.
Surgeons; Messrs. Key, Morgan, and B. Cooper.	Ditto.	Surgeon's pupil, 6 mos. 20l.; 12 mos. 26l. 6s.; Dresser, 6 mos. 32l. 12s.; 12 mos. 51l. 2s.

*Medicine.* Clinical lectures will be given by the physicians. Demonstrations in morbid anatomy by Dr. Hodgkin. Price for a catalogue of the museum, 15s.

*Midwifery and Physiology.* Pupils of two or more courses of midwifery become perpetual to physiology, by entering for one course.

*Anatomy.* Lectures on the anatomy and diseases of the teeth are included in this course, and will be given by Mr. Bell. *Comp. Anat.*; by Mr. Morgan and Mr. Bell.

*Hospital Practice.* Clinical Instructions will be given by the surgeons. Demonstrator, Mr. Edward Cock; assistant demonstrators, Mr. Smith and Mr. Hilton. Pupils entering to the surgical practice of Guy's Hospital, are allowed to attend that of St. Thomas's. [Pupils will be permitted the use of the library, reading room, and botanic garden, subject to regulations.]

## ST GEORGE'S HOSPITAL.

Classes and Lecturers.	Days and Hours of Lectures.	Fees to the Courses.
Medicine; Drs. Chambers and M'Leod.	Mon. Wed. and Fri. at 11½ a.m.	1st C. 3l. 3s.; 2nd C. 2l. 2s.; P. 6l. 6s.
Surgery; Messrs. Brodie and Hawkins.	Mon. Wed. and Fri. at 7 a.m.	1st C. 3l. 3s.; P. 5l. 5s.
Materia Medica; Drs. M'Leod and Seymour.	Tues. Thurs. and Sat. at 11½ a.m.	1st C. 3l. 3s.; 2nd C. 2l. 2s.; P. 6l. 6s.
Midwifery and Diseases of Women and Children; Mr. Stone and Dr. H. Davies.	Mon. Wed. and Fri. at 10½.	Each C. 3l. 3s.; P. 5l. 5s.
Botany; Mr. G. Burnett.	Tues. Thurs. and Sat. at 7 p.m.	One C. 1l. 1s.; P. 2l. 2s.
Hospital Practice; Physicians, Drs. Hewitt, Seymour, and Wilson.	The physicians and surgeons attend usually at 12½ each day. Patients received on Wed. Operations on Thur. at 1 p.m.	Physician's pupils; 9 mos. 12l. 12s.; 12 mos. 16l. 16s. P. 25l. 4s.; fee to apothecary 1l. 1s.
Surgeons; Messrs. Brodie, Keate, and Hawkins.	.....	Surgeon's pupils; 6 mos. 15l. 15s.; 12 mos. 21l.; P. 52l. 10s.

*Hospital Practice.* Clinical lectures are given gratuitously to the pupils of the hospital, by Drs. Hewitt and Seymour, and Messrs. Brodie and Hawkins; and lectures on pathology, by Dr. Wilson, of which notice will be given. Pupils entering for twelve months, are allowed to dress the patients for three months without additional fee; the perpetual pupils are entitled to dress twice, and also to be house surgeons when properly qualified for the office.

## LONDON HOSPITAL.

Classes and Lecturers.	Days and Hours of Lectures.	Fees for the Courses.
Medicine; Dr. Billing.	Tues. Thur. Fri. at 3½ p.m.	1st C. 4l. 4s.; 2nd C. 3l. 3s.; two C., 6l. 6s.; P. 7l. 7s.
Materia Medica and Medical Botany; Dr. Cobb.	Wed. and Fri. at 9 a.m.	1st C. 3l. 3s.; 2nd C. 2l. 2s.; P. 4l. 4s.
Midwifery, and Diseases of Women and Children; Dr. Ramsbotham and Dr. F. H. Ramsbotham.	Mon. Wed. and Fri. at 10 a.m.	1st C. 3l. 3s.; 2nd C. 2l. 2s.; P. 8l. 8s.
Chemistry; Dr. Gordon.	Tues. Thur. and Sat. at 10 a.m.	1st C. 4l. 4s.; 2nd C. 3l. 3s.; two C. 6l. 6s.; P. 8l. 8s.
Anatomy, Physiology, and Operations; Mr. Headington and Mr. Luke.	Daily at 1½ p.m.	1st C. 5l. 5s.; 2nd C. 4l. 4s.; 3rd C. 3l. 3s.; P. 10l. 10s.
Surgery; Mr. Luke.	Mon. and Wed. at 7 p.m.	1st C. 3l. 3s.; P. 5l. 5s.
Demonstrations and Dissections; Messrs. Adams and Hamilton.	Daily at 11½ a.m.	3 C. each 3l. 3s.; P. 10l. 10s.
Hospital Practice; Physicians, Dr. Frampton, Dr. Billing, Dr. Gordon.	Clinical Lectures by Drs. Billing and Gordon, on Sat. at 3½ p.m.	Physician's pupils, 9 mos. 10l. 10s.; 12 mos. 15l. 15s.; P. 20l.; Apothecary's fee, 1l.
Surgeons; Sir W. Blizard, Mr. Headington, Mr. Andrews.	Clinical observations occasionally by Sir W. Blizard.	Surgeon's pupil, 6 months 21l.; 12 mos. 31l. 10s.; Library 1l.

The surgical lectures are free to students of the anatomical class.

## MIDDLESEX HOSPITAL.

THE only lectures at this hospital are *Clinical Lectures*, delivered by Mr. C. Bell to the physician's pupils, and lectures on *Midwifery, and the Diseases of Women and Children*, by Dr. Ley.

The cost of attendance on the *Hospital Practice* is as follows:—Physician's pupil, 6 mos. 10l. 10s.; 9 mos. 12l. 12s.; 12 mos. 15l. 15s. Perpetual, 22l. 1s.—Surgeon's pupil: 3 mos. 10l. 10s.; 6 mos. 15l. 15s.; 12 mos. 21l. Perpetual, 52l. 10s.—Dresser for 6 mos. 21l.; for 12 mos. 31l. 10s.—Entrance fee to the apothecary, 1l. 1s.—To the secretary, 5s. From the dresser the house-surgeon is elected agreeably to his date of entrance. A pupil may be allowed 3 mos. dressing, by paying 10l. 10s. extra. The physicians and surgeons visit at 12 on Mon. Wed. and Sat. The taking-in day is Tues. at 12. The out-patients are seen on Thurs.

Dr. Ley's lectures commence on Monday, Oct. 11th. His terms are, for a single course, 3l. 3s. Perpetual, 5l. 5s., which latter will give the liberty of attending Dr. Ley's practice at the hospital. The student, when qualified, will have opportunities of attending labours.

## WESTMINSTER HOSPITAL.

CLINICAL LECTURES are occasionally given by the physicians and surgeons, and are the only lectures delivered in this hospital.

The cost of attendance on the *Hospital Practice* is as follows:—Physician's pupils (admitted to attend the practice of the physicians) for 6 mos. to pay 10l. 10s.; for one year, 15l.; perpetual, 21l.—Surgeon's pupils (admitted to attend the practice of the surgeons) for 6 mos. 12l. 12s.; perpetual, 21l. Pupils are allowed in turn to become dressers without an additional fee, on expressing a desire to that effect to the house-surgeon.

## THEATRE OF ANATOMY AND MEDICINE,

*Webb Street, Maze Pond, Borough.*

Classes and Lecturers.	Days and Hours of Lectures.	Fees for the Course.
Anatomy and Physiology, Demonstrations, &c.; Messrs. Grainger and Pilcher, with Mr. C. Millard.	Daily, at 2 p.m.; Examinations weekly.	Lectures and Dissections; one C. 6 <i>l.</i> 5 <i>s.</i> ; two C. 8 <i>l.</i> 8 <i>s.</i> ; P. 10 <i>l.</i> 10 <i>s.</i>
Medicine; Dr. Boott.	Mon. Wed. and Fri. at 4 p.m.	One C. 4 <i>l.</i> 4 <i>s.</i> ; two C. 6 <i>l.</i> 6 <i>s.</i> ; P. 8 <i>l.</i> 8 <i>s.</i>
Materia Medica and Botany; Dr. Boott.	Tues. Thur. and Sat. at $\frac{1}{2}$ 10 a.m.	One C. 3 <i>l.</i> 3 <i>s.</i> ; two C. 4 <i>l.</i> 4 <i>s.</i> ; P. 5 <i>l.</i> 5 <i>s.</i>
Chemistry; Mr. Cooper.	Mon. Wed. and Fri. at $\frac{1}{2}$ 10 a.m. Examinations weekly.	One C. 4 <i>l.</i> 4 <i>s.</i> ; 2nd C. and each after, 2 <i>l.</i> 2 <i>s.</i> ; P. 6 <i>l.</i> 6 <i>s.</i>
Midwifery, and Diseases of Women and Children; Dr. R. Lee.	Tues. Thur. and Sat. at 4 p.m.	One C. 3 <i>l.</i> 3 <i>s.</i> ; two C. 5 <i>l.</i> 5 <i>s.</i> ; P. 6 <i>l.</i> 6 <i>s.</i>

*Anatomy, &c.* Mr. Grainger delivers the introductory lecture at  $\frac{1}{2}$  11 a.m., Friday, October 1st.

*Medicine.* The first lecture, Friday, Oct. 1st, at 4 p.m. The same course will be delivered at 24, Gower Street, Bedford Square, at 8 a.m. of the same days as in Webb Street.

*Materia Medica and Botany.* The first lectures on materia medica, Tuesday, Oct. 5, at  $\frac{1}{2}$  10 a.m. On botany, Saturday, Oct. 12, at  $\frac{1}{2}$  10, and the courses repeated at 8 a.m. in Gower Street. A large cabinet is fitted up with good and bad specimens of every medicine now in use, and with botanical drawings; all of which will be open to the daily inspection of those students who attend this course of materia medica. In the summer season, Dr. Boott will accompany students on weekly botanical excursions in the neighbourhood of London.

*Midwifery, &c.* Labours free of expense to the pupils. [Mr. Highley is authorized to enter pupils to all the above lectures.]

## MEDICAL SCHOOL,

53, Aldersgate Street.

Classes and Lecturers.	Days and Hours of Lectures.	Fees for the Course.
Anatomy and Physiology; Mr. Jones Quain.	Daily, at 2 $\frac{1}{2}$ a.m.	One C. 3 <i>l.</i> 3 <i>s.</i> ; two C. 5 <i>l.</i> 5 <i>s.</i> ; P. 6 <i>l.</i> 6 <i>s.</i>
Anatomy with Dissections; Mr. J. Quain and Mr. Evans.	Daily.	One C. 3 <i>l.</i> 3 <i>s.</i> ; two C. 4 <i>l.</i> 4 <i>s.</i> ; P. 6 <i>l.</i> 6 <i>s.</i> Perpetual to all the above, 10 <i>l.</i> 10 <i>s.</i>
Surgery; Mr. Tyrrell.	Tues. Thurs. and Fri. at 7 p.m.	One C. 3 <i>l.</i> 3 <i>s.</i> ; P. 5 <i>l.</i> 5 <i>s.</i>
Medicine; Dr. Clutterbuck.	Mon. Wed. and Fri. at 10 a.m.	One C. 3 <i>l.</i> 3 <i>s.</i> ; two C. 5 <i>l.</i> 5 <i>s.</i> ; P. 6 <i>l.</i> 6 <i>s.</i>
Materia Medica; Dr. C. J. Roberts.	Tues. Thur. and Sat. at 10 a.m.	One C. 3 <i>l.</i> 3 <i>s.</i> ; 2nd C. 2 <i>l.</i> 2 <i>s.</i> ; P. 4 <i>l.</i> 4 <i>s.</i>
Chemistry; Mr. Cooper.	Tues. Thur. and Sat. at 11 a.m.	One C. 4 <i>l.</i> 4 <i>s.</i> ; 2nd C. 2 <i>l.</i> 2 <i>s.</i> ; P. 6 <i>l.</i> 6 <i>s.</i>
Midwifery, and Diseases of Women and Children; Mr. Waller.	Tues. Wed. and Fri. at $\frac{1}{2}$ 6 p.m.	One C. 3 <i>l.</i> 3 <i>s.</i> ; two C. 5 <i>l.</i> 5 <i>s.</i> ; P. 7 <i>l.</i> 7 <i>s.</i>

*Anatomy and Dissections.* Entry as perpetual pupil to both, 10*l.* 10*s.*

*Materia Medica, Chemistry, and Midwifery.* Perpetual entry to these three, 14*l.* 14*s.* A cabinet of materia medica will be at all times open for the inspection of the pupils. Pupils, when duly qualified, will have ample opportunities of attending labours free of expense. Obstetrical examinations and conversations will be held, during the season, at Mr. Waller's residence. Prizes as usual in the spring.

Entry to the lectures, certificates of which are required at the Royal College of Surgeons, and at Apothecaries Hall, 321. 11s. Perpetual to all the lectures, 34l. 13s. The above lectures are so arranged, as not to interfere with one another, nor with the attendance on the practice at the hospitals. The lectures commence Friday, Oct. 1st.

### THEATRE OF ANATOMY, *Little Windmill Street.*

Classes and Lecturers.	Days and Hours of Lectures.	Fees for the Courses.
Anatomy, Physiology, &c., with Demonstrations and Dissections; Mr. E. W. Tuson.	Daily at 2½. Commence Oct. 1st.	One C. 5l. 5s.; P. 15l. 15s. Old pupils, P. 10l. 10s.
Surgery; Mr. Guthrie. Medicine; Dr. Sigmond.	Not announced. Mon. Wed. and Fri. at 4 a.m. Commence Oct. 4. Tues. Thur. and Sat. at 9 a.m. Commence Oct. 5.	One C. 3l. 3s.; P. 5l. 5s. One C. 3l. 3s.; P. to these and Dr. Steward's, 8l. 8s. One C. 3l. 3s.; P. to these and Dr. Sigmond's, 9l. 8s.
Materia Med., Chemistry, and Botany; Dr. Steward.	Tues. Thur. and Sat. at 7 p.m. Commence Oct. 2.	One C. 3l. 3s.; P. 5l. 5s.
Midwifery, &c.; Mr. Jewel.		

*Anatomy, &c.* Mr. Tuson delivers three courses during the year, each commencing the first day in Oct. Feb. and June. A private course of anatomical instructions and examinations to gentlemen who wish speedily to qualify themselves for the College or Hall.

*Surgery.* Clinical lectures on surgery will be delivered by Mr. Guthrie at the Westminster Hospital, and on the diseases of the eye at the Royal Westminster Ophthalmic Hospital.

*Midwifery.* Cases provided for pupils without expense, with clinical instruction. Apprentices of practitioners, resident in town, will be furnished with cases at times the best suited to their convenience. Members of the Royal College of Surgeons, and medical officers in the public services, will be presented with gratuitous tickets of admission to the lectures upon application to Mr. Jewel. Gentlemen in actual practice, not members of the College, will be free to the lectures upon payment for one course.

### LONDON FEVER HOSPITAL

CONTAINS sixty beds, has two attending physicians, a resident medical officer, and, taken altogether, is one of the best-conducted hospitals in London. The visiting physicians are Dr. Tweedie and Dr. Southwood Smith, who attend daily, and will deliver clinical lectures, if a sufficient number of pupils enter. The cases are regularly taken, daily reports are made, and the books are left in the wards for inspection. The entry to perpetual attendance is ten pounds ten shillings.

### THEATRE OF MEDICINE AND CHEMISTRY,

*No. 1, Dean-street, Borough.*

*Medicine*, by Dr. Whiting; on Mondays, Wednesdays, and Fridays, at 5½ p.m. The Introductory Lecture will be given Oct. 1st, at 5½ p.m. Terms: one course, three guineas; two courses, five guineas; perpetual, six guineas.

*Materia Medica and Botany*, by Dr. Whiting; on Tuesdays, Thursdays, and Saturdays, at 4 to 10 p.m. The introductory Lecture will be delivered on Saturday evening, at 5½ p.m. Terms: one course, three guineas; perpetual, at one payment, four guineas; one course of theory and practice

of Medicine, and one Materia Medica, five guineas; two courses of each, eight guineas; perpetual to both, ten guineas. The lectures on Materia Medica will be illustrated by chemical demonstrations, specimens of drugs, dried plants, and botanical drawings.

*Chemistry*, by Mr. Everitt; on Mondays, Wednesdays, and Fridays, at 4 to 10 a.m. The Introductory Lecture will be delivered Oct. 1st, at 4 to 10 a.m. Terms: one course, three guineas; two courses, five guineas; perpetual, six guineas (*Chemical Manipulation*).—Instruction given in practical chemistry, to gentlemen wishing to study this science more especially, in the laboratory connected with the Theatre; by Mr. Everitt.

*Midwifery, and Diseases of Women and Children*, by Dr. Russell; on Mondays, Wednesdays, and Fridays, at  $\frac{1}{2}$  to 4 A.M. Terms: one course, three guineas; two courses, five guineas; perpetual, six guineas. Gentlemen entering to these lectures may attend the cases of the Lying-in Charity, established in the Borough.

NEW MEDICAL SCHOOL,

34, *Brewer Street, Windmill Street, Golden Square.*

Anatomy, physiology, pathology, demonstrations, and dissections, by Mr. Sleigh and Mr. Costello, one course, 5*l.* 3*s.*; perpetual, 12*l.* 12*s.* To those who have entered elsewhere, perpetual, 6*l.* 6*s.* The principles and practice of medicine, by Dr. Ryan, one course, 3*l.* 3*s.*; perpetual, 5*l.* 5*s.* The principles and operations of surgery, by Mr. Sleigh, one course, 2*l.* 2*s.*; perpetual, 4*l.* 4*s.* Chemistry, Materia Medica, and Botany, by Dr. Epps, one course, 4*l.* 4*s.*; perpetual, 6*l.* 6*s.* Midwifery, and the diseases of women and children, by Dr. Ryan, one course, 3*l.* 3*s.*; perpetual, 5*l.* 5*s.* Natural Philosophy, by Mr. Browne, one course, 2*l.* 2*s.*; perpetual, 4*l.* 4*s.* Perpetual to lectures on practice of physic and midwifery, 8*l.* 8*s.* A system of catechetical lectures on anatomy, physiology, pathology, and surgery, by Mr. Sleigh. The pupils of this class, free; to others for the season, 5*l.* 5*s.* The school will open with Mr. Sleigh's introductory lecture, on Friday, Oct. the 1st, at 9 p.m.

SURREY DISPENSARY,

*Union Street, Borough.*

*Medical Practice.* Pupils entering to this institution are entitled to attend every day in the week (Sundays excepted) Clinical observations upon the cases and clinical lectures will be delivered by the physicians. Weekly examinations by the apothecary in materia medica, pharmaceutical chemistry, and the practice of physic. Botanical drawings, and a collection of materia medica, are kept for the use of the pupils. Physicians; Dr. Forbes, Dr. Roe, Dr. Whiting.—Terms of attendance, for six months, 5*l.* 5*s.*; from six to twelve months, 7*l.* 7*s.*; perpetual, 12*l.* 12*s.*

CENTRAL INFIRMARY AND DISPENSARY,

*Greville Street, Hatton Garden.*

Gentlemen are admitted to attend the medical and surgical practice of the institution. Terms of medical attendance: perpetual, 8 guineas; twelve months, 5 guineas.

Dr. Ramadge commences his lectures on medicine, materia medica, medical botany,

and chemistry, in October, February, and May, at a quarter before eight A.M. Terms:—Lectures on the theory and practice of physic, and examinations; for one course, 3 guineas; perpetual, 5 guineas. Lectures on chemistry, materia medica, and medical botany; for one course, 3 guineas; perpetual, 5 guineas; perpetual to all the lectures, 8 guineas. Gentlemen entering as perpetual pupils to the lectures and medical practice, are entitled to opportunities of examining dead bodies, and of attending (gratuitously) the infirmary for asthma, consumption, &c. Evening examinations and clinical instructions will be given on alternate evenings, to which all medical students may obtain gratuitous admission.

GENERAL DISPENSARY,

36, *Aldersgate Street.*

Attendance on the medical practice of this institution is permitted. During the winter season, gratuitous clinical and other lectures are delivered weekly. A cabinet of materia medica is kept for the use of pupils. Consulting-physician, Dr. George Birkbeck. Physicians; Dr. Clutterbuck, Tues. and Fri., at 1 p.m.; Dr. Lambe, Wed. and Sat., at 1 p.m.; Dr. C. I. Roberts, Mon. and Thurs., at 1 p.m. Terms, for an unlimited period, seven guineas.

*Surgery*; Mr. King, four years surgeon interne at the *Hotel Dieu*, and late of the Aldersgate Street School, intends delivering complete courses of lectures on surgery and medical jurisprudence during the ensuing session. The arrangements are not yet finally completed, but we believe Mr. King has it also in contemplation to form a new school, the leading principle of which is to be, "that the permanent interests of the pupils should form the basis of all its regulations."

*Anatomy and Surgery.* Mr. Carpue, 72, Dean Street, Soho, will commence his lectures on Friday, Oct. 1st, and continue them daily at 9 A.M.

*Anatomy, Physiology, and Surgery.* Mr. Dermott, Westminster Dispensary, 9, Gerard Street, Soho, will give Lectures and Demonstrations. Lectures, daily, half-past three P.M. Demonstrations, half-past ten A.M. Dissections continued through the day. The introductory lecture, half-past three P.M., October 1. Perpetual to the whole, 10*l.* 10*s.* Old pupils, 5*l.* 5*s.* Gentlemen in practice, gratuitous. Private catechetical instruction till qualified to pass, 5*l.* 5*s.*

**Surgery.** — Mr. Howship, 21, Saville-row, will commence a course of lectures on the principles and practice of Surgery, on the first Monday in Oct. at eight p.m., and continue them every evening, (Sundays excepted) at the same hour. Two courses are given during the season, which begins in Oct. and terminates in June. The weekly examination of the students is held every Saturday evening, from nine to ten. Terms: each course, three guineas; perpetual, five guineas. Medical officers of the army or navy, on presenting a letter of introduction from the heads of their respective departments, will be considered entitled to a card.

**Anatomy, Physiology, &c.** Mr. Greville Jones, 8, Hatton Garden, will deliver a course of two divisions on the above branches, and on their application to pathology and surgery; with daily examinations and dissections. Terms, one course of lectures, 4*l.* 4*s.* One course of demonstrations, 3*l.* 3*s.* Perpetual to the whole, 10*l.* 10*s.* Private instruction is also afforded. Commence, Tuesday, October 5, at half-past two p.m.

**Anatomy, Physiology, Pathology, and Surgery.** Mr. H. Mayo gives two courses of lectures annually; one of which commences on the 1st of October, and terminates towards the middle of January; the second commences on the 20th of January, and terminates early in May. A lecture is given daily (Wednesdays excepted), beginning at half-past two o'clock. A room is opened for dissections from the 10th of October to the 20th of April; during this period an anatomical demonstration will be given daily by Mr. Tatum. Examinations are held twice a week. Terms of anatomical lectures: 1st course, 5*l.* 5*s.*; 2nd course, 4*l.* 4*s.*; 3rd course, 3*l.* 3*s.*; perpetual, 10*l.* 10*s.* Demonstrations and dissections, each course, 3*l.* 3*s.*; perpetual, 10*l.* 10*s.*

**Anatomy and Surgery.** Mr. Smith, 47, Gerard Street, Soho Square, commences his lectures on anatomy and physiology, with demonstrations and dissections, the first week in October. Anatomy and physiology, a lecture daily. Single course, 3*l.* 3*s.*; two courses, entered together, 5*l.* 5*s.* Demonstrations with dissections, &c., by and under the daily superintendence of Mr. Smith: single course, 3*l.* 3*s.*; two courses entered together, 4*l.* 4*s.* For entry to anatomy, demonstrations, surgery, and examinations, single course, 5*l.* 5*s.*; two courses entered together, 8*l.* 8*s.* Principles, practice, and operation of surgery, a lecture three times a week; single course, 2*l.* 2*s.* Perpetual to

the whole of the lectures, demonstrations, &c., 10*l.* 10*s.*

**Surgery.** Mr. Evans Riadore will commence his course of lectures on the principles and practice of surgery, on the 6th of October, at 8 p.m., at his residence, 17, Tavistock Square, and to be continued daily. Two courses will be delivered during the season, commencing as above and ending in May. Each perpetual pupil will have an opportunity of performing nearly all the operations in surgery on the dead subject, at Mr. Evans Riadore's expense, and under his instructions, and every pupil may perform the minor operations, including the application of dressing and bandages, the stethoscope, stomach pump, &c. An examination will be held every Saturday evening after lecture. Terms, two courses, 3*l.* 3*s.*; perpetual, 5*l.* 5*s.*

**Anatomical Demonstrations and Dissections.** Mr. Lowe Wheeler, 18, Giltspur Street, will deliver two courses in the season, at 11 a.m. daily, commencing on Saturday, Oct. 2. Terms, one course, 3*l.* 3*s.* Perpetual, 8*l.* 8*s.*

**Anatomy, Physiology, and Diseases of Domestic Animals.** Mr. Youatt, 3, Naasau Street, Middlesex Hospital, will begin two courses of sixty lectures each on the above branches, on Tuesday, Oct. 12, at 8 p.m., and continue them on each Tuesday, Thursday, and Saturday, at the same hour. These lectures will illustrate to the medical student the adaptation of structure in domestic animals, to the various purposes for which they were destined; the modification of function which a variety of organisation occasions; and the character and treatment of disease resulting from difference of structure and function. To the veterinary pupil and amateur the lectures present an equal source of interest. Terms, each course, 3*l.* 3*s.*, or both courses, 5*l.* 5*s.*

**Physiology, Pathology, and Morbid Anatomy.** Mr. Wade will deliver a course of lectures at the Westminster General Dispensary, 9, Gerrard Street, Soho, at 8 p.m. every Tuesday during the season, commencing Oct. 5th, on the above subjects, in illustration of their practical application to medicine and surgery. Terms: one course, 1*l.* 1*s.*; perpetual, 2*l.* 2*s.*

**Medicine, Materia Medica, Botany, and Medical Classics.** Dr. Collier, 32, Spring Gardens, instructs pupils in the above branches. The terms for the whole course, which is intended to be commensurate with what is required by the new regime of the

Apothecaries' Hall, are 211. Medical officers of the navy and army, half the fee, with private examinations, &c. prior to their official examinations.

**Medicine, Midwifery, and Medical Jurisprudence.** Dr. Ryan will commence his lectures on these branches in October, February, and May. Principles and practice of medicine, one course, 31. 3s.; perpetual, 51. 5s. Midwifery, one course, 31. 3s.; perpetual, 51. 5s. Medical Jurisprudence, one course, 21. 2s.; perpetual, 31. 3s. Perpetual to all the lectures, 81. 8s.

**Medicine, Materia Medica, Botany, &c.** Dr. Tweedie will commence his lectures on the Theory and Practice of Medicine, at his Class Room, No. 90, Bartholomew-close, on Saturday, the 2d Oct. at ten A. M. These lectures will be continued on Mondays, Wednesdays, and Fridays, till the conclusion of the course. Dr. Tweedie's lectures on Materia Medica, including Therapeutics and Medical Botany, commence on Tuesday, the 5th Oct. at ten A. M. and will be continued on Tuesdays, Thursdays, and Saturdays, at the same hour. Terms: Medicine, for one course three guineas, for two courses five guineas; Materia Medica and Therapeutics, for one course three guineas, for two courses four guineas; perpetual to both courses, seven guineas.

**Medicine, Chemistry, and Materia Medica.** Dr. Ager, 85, Great Portland Street, commences his lectures on the above branches, on Monday, Oct. 4, at 8½ A. M. Examinations are held. Terms—Theory and practice of physic, 1st course, 41. 4s.; 2nd course, 31. 3s.; perpetual, 81. 8s.—Chemistry and Materia Medica, the same. Single course of all the lectures, 71. 7s.; perpetual, 101. 10s. The lectures on the materia medica will be continued every Mon. Wed. and Fri.; those on chemistry every Tues. Thur. and Sat., at the same hour. The lectures on the practice of physic will begin after the first course on the materia medica, two courses of each will be given every year.

**Medicine.** Dr. G. Gregory will commence a course of lectures on the theory and practice of physic, on Monday, October 4, at 9 A. M., at the St. George's and St. James's Dispensary, 60, King Street, Golden Square, to be continued on Mondays, Wednesdays, and Fridays, from nine to ten o'clock; three courses are given during the year. The first commences in October; the second about the 20th of January; and the third in May, terminating early in August. The

lectures on Variola and its modifications will be illustrated by a clinical commentary on cases in the Small Pox Hospital.

**Materia Medica, Medical Botany, &c.** Dr. Webster, in connexion with the above, will deliver a course of lectures on materia medica, medical botany, and pharmacy, on Mondays, Wednesdays, and Fridays, from eight to nine o'clock; three courses are given in each year. A cabinet is always open for the inspection of pupils. Terms:—For the practice of physic; one course, 31. 3s.; two courses, 51. 5s.; perpetual, 71. 7s. For Materia Medica; one course, 21. 2s.; two courses, 41. 4s.; perpetual, 51. 5s.; for two courses of the practice, with two of materia medica, 81. 8s.; perpetual to both courses, 101. 10s. Pupils are admitted to attend the medical practice of the St. George's and St. James's Dispensary, and of the Small Pox and Vaccination Hospital at St. Pancras.

**Chemistry, Materia Medica, and Medical Botany.** Mr. Pereira, General Dispensary, 36, Aldersgate Street, will commence a course of lectures on chemistry, on Saturday, October 2, at ten A. M., to be continued every Tuesday, Thursday, and Saturday, from ten to eleven A. M. Terms, one course, 51. 5s.; perpetual, 51. 5s. And a course of lectures on materia medica, &c., on Wednesday, October 6, at half-past four P. M. Terms, one course, 11. 1s.; perpetual 41. 4s. The course well illustrated, and examinations held. Pupils entering to both of the above courses, for one course of each, 41. 4s.; two of each, 51. 5s.; perpetual to the whole, 61. 6s.

**Chemistry, Materia Medica, Botany, &c.** Mr. J. L. Wheeler, 18, Giltspur Street, will commence a course of lectures on the above subjects on Friday, Oct. 1st. Terms: Chemistry, one course, 31. 3s.; perpetual, 61. 6s. Materia medica, one course, 21. 2s.; perpetual, 41. 4s.; perpetual to both, 71. 7s.

**Chemistry.**—Mr. Brande and Mr. Faraday will deliver a course of lectures on Chemistry, in the laboratory of the Royal Institution, to commence Oct. 5th, at 9 A. M., and to be continued every Tuesday, Thursday, and Saturday. Two courses are given during the season, which terminates in June. Terms: The admission fee to each course is 41. 4s.; or, by paying 81. 8s., gentlemen are entitled to attend for an unlimited time. Gentlemen, who are in actual attendance at the medical and anatomical schools in London, are admitted to attend two courses of the above lectures, upon the payment of six guineas. Life and annual subscribers to the Royal Institution are admitted to the

above lectures, on payment of two guineas for each course; or, by paying 6*l.* 6*s.*, are entitled to attend for an unlimited time.

**Medical Botany.** Mr. Houlton, No. 11, Grove-place, Alpha-road, will give two courses of lectures on Botany, as applied to Medicine, during the ensuing session; commencing on the first Wednesday in Oct. and May, at eight A. M., and to be continued at the same hour every Wednesday and Saturday morning. Mr. Houlton has in cultivation, at his residence, upwards of one hundred of the most important medicinal plants. **Terms:** one course, one guinea; perpetual, two guineas.

**Midwifery, and Diseases of Women and Children.** Mr. Shipman, 2, Guilford Street, Russel Square, will commence his lectures on the above subjects, on Tuesday the 5th of October, at eight o'clock in the evening, and will continue them every Tuesday and Thursday at the same hour. Pupils, when duly qualified, will have an ample supply of cases. **Terms,** one course, 2*l.* 2*s.*; two courses, 3*l.* 3*s.*; perpetual, 5*l.* 5*s.*

**Midwifery, and Diseases of Women and Children.** Dr. Power, 6, Leicester Place, Leicester Square, commences his lectures on the above branches, on Tuesday, Oct. 5, at 4 P. M., and continues every Tuesday, and Saturday, at 4 P. M. Pupils, when qualified, will have cases of labour to attend gratuitously. Examinations weekly. **Terms,** one course, 2*l.* 2*s.*; two courses, 4*l.* 4*s.*; perpetual, 5*l.* 5*s.*

**Midwifery, and Diseases of Women and Children.** Dr. Thomas Blundell will commence his autumnal course on the above subjects, on Friday, October 1st, at 7 P. M., at 90, Bartholomew Close, and continue the same on every alternate evening at that hour. Pupils when qualified supplied with cases gratuitously. **Terms:** For one course, 3*l.* 3*s.*; Perpetual, 5*l.* 5*s.* Army and Navy surgeons are free to these lectures.

**Anatomy, Physiology, and Pathology of the Ear.** Mr. John Harrison Curtis will commence a course of lectures on the above subject on Friday, 1st October, at 7 P. M., at the Royal Dispensary for Diseases of the Ear, 10, Dean-street, Soho-square; to be concluded in May. A Clinical lecture will be given occasionally, on the most important cases that occur at the Royal Dispensary. The Royal Dispensary is open to Pupils. **Terms:** attendance, three months, 5*l.* 5*s.*;

six months, 8*l.* 8*s.*; perpetual, 10*l.* 10*s.*; lectures, single course, 2*l.* 2*s.*; two courses, 3*l.* 3*s.*; perpetual, 5*l.* 5*s.*

**Forensic Medicine.** Dr. O'Shaughnessy will commence a course of lectures on Forensic Medicine early in October, the particulars of which will shortly be announced.

**Medical Jurisprudence.** Mr. Mingay Syder, Borough, will give instruction in the above branch, on Thursdays and Saturdays, at eight P. M.

**Tuition for the College, Hall, and Public Boards.**—Dr. Durie, 26, Thavies Inn, Holborn, gives private instruction to gentlemen preparing for examination at the above institutions on all the requisite branches of medical science and medical Latin, with the use of an arranged cabinet of drugs. **Terms:** Apothecaries' Hall or College (private pupils) per month, 2*l.* 2*s.*; unlimited time, 5*l.* 5*s.* A class meeting daily, and limited to six with Latin. Apothecaries' Hall or College (each pupil), per month, 3*l.* 3*s.*, *pro re nata*. Medical Latin *per se*:—in a class per quarter (twice a week), or per month (daily), each pupil, 2*l.* 2*s.*; private pupils ditto, 4*l.* 4*s.*

**Private Tuition for the College, Hall, and Public Boards,** is given by Messrs. Harding and Evans, 14, Beak Street, Regent Street. **Terms** for preparing for examination at each institution, 5*l.* 5*s.*

**Tuition for the College and Hall.** Mr. Hawker, 4, Weston Street, Maze Pond, Borough, will continue to form classes during the session, preparatory to the College and Hall examinations.

**Medical Classics.** Mr. J. H. Underwood, 41, Leicester Square, will hold Latin classes for medical students in the Borough, on Mondays, Wednesdays, and Fridays, at half-past six P. M., commencing October 1; and a class in Leicester Square on Tuesdays, Thursdays, and Saturdays, at seven P. M. **Terms** for the course, 3*l.*

**Medical Classics.** Mr. Dunne, 13, Manchester Buildings, Parliament Street, Westminster, has an establishment for teaching medical classics on a new plan, the terms of which are—for one course, 3*l.* 3*s.*; two courses, 5*l.* 5*s.*; three courses, 7*l.* 7*s.*

## THE LANCET.

*London, Saturday, September 25, 1830.*

THE medical session for 1830-31 is just about to commence, and the faces of many new pupils are already to be seen in the neighbourhood of the University and the larger Hospitals. The prospectuses of the various schools have been issued, and so numerous are they that the counters of the medical booksellers groan beneath the ponderous weight. Into the merits or demerits of the particular establishments we shall not enter, but the pupil may find a few admonitory remarks on this subject that he might read with advantage in No. 318 of this Journal. The student should bear in mind, that it is far more easy to utter promises than to fulfil the obligations which these promises impose. The deceptions that have been practised in this respect have led to the ruin of many deserving young men, and embittered the lives of hundreds of parents. Young gentlemen on their first arrival in London cannot exercise too much caution in selecting associates, nor can they too resolutely determine not to be influenced in their selection of a school by the advice of persons with whom they may be altogether unacquainted; for it is a well-known fact, that certain establishments place their "decoys," towards the latter end of September, and the beginning of October, in all parts of the metropolis, in order that the unprincipled schemers may entrap and plunder the unsuspecting student on his first arrival in London. Too much caution, therefore, cannot be practised by the student. Before he engages to attend any one school, he should well mature the whole of his arrangements, he should particularly notice the time at which the various lectures are to be delivered, the distance of the class-rooms from each other, the hours that would be required for Hospi-

tal attendance, and for other pursuits. If he be not attentive to these circumstances, he may find, when it is too late, that he has paid for "courses" which it will be impossible for him to hear, as he may have entered to lectures which are delivered on similar days and hours, or he may have engaged to attend others at the very moment when his presence will be required at the Hospital.

The "regulations" of the College of Surgeons and the Company of Apothecaries should be carefully consulted, in order that the entries to the lectures may be in strict accordance with the rules there laid down. An error on this point might cause much inconvenience, and a heavy, vexatious expense. The Hospitals of this metropolis offer ample opportunities for acquiring a practical knowledge of medicine, and the student will be richly rewarded in after life if he be industrious and zealous in acquiring information at the bedsides of the sick. He should not, however, disturb the wretched sufferers by unnecessary questions or manipulations; indeed, it were well if he would refrain from interference in the absence of the surgeon or physician; but when those officers are present, he should on all doubtful points seek to obtain information. This is not less the pupil's duty than it is the surgeon's duty to grant it. The governors of the Hospitals, we believe, are desirous, as far as they have knowledge, of assisting the pupils in the progress of their studies; but those who have paid for instruction should bear in mind that a moral obligation is imposed upon them both by their relatives and by society, to insist upon receiving that instruction for which so high a charge is made. If the surgeons and physicians fail to fulfil their contract, the student should appeal to the public through the press, not however until a respectful appeal, made in the proper quarter, has failed to accomplish the wished-for object. Those pupils who enter to the practice of

the hospitals, ought to require that the names of the diseases with which the patients are afflicted should be attached to the beds, that due notice of all operations, except those performed upon emergency, should be posted in the surgery of the hospital or the lobby of the theatre, and that a case-book, containing a succinct account of each disease, together with the medicines prescribed in the treatment, should be kept in every ward of the hospital. Further, the pupils should call on the surgeon or physician to explain orally, immediately after leaving the ward, the nature and peculiarities of the most dangerous of the diseases, the causes of the most prominent symptoms, and the principles upon which his treatment is founded. If the pupils would but conduct themselves respectfully, firmly, and intelligently, the physicians and surgeons must soon very faithfully discharge the obligations imposed by their prospectuses, and immense indeed would be the advantage that must accrue to the public from so beneficial an alteration in the present system.

#### ST. JOHN LONG.

ARRANGEMENTS were made for presenting a bill of indictment for manslaughter against Mr. ST. JOHN LONG, to the Grand Jury at the Sessions House, Clerkenwell, on Friday morning last. As Mrs. RODDIS, one of the chief witnesses for the prosecution, was unable to attend in consequence of severe indisposition, we considered it to be our duty to move the court for a postponement of the case to the next session, which request, under the circumstances, was of course readily granted. It is not a little singular that the witnesses for the defence were in attendance in a snug little room on Clerkenwell Green. Marchionesses, Honourable Misses, Generals, and, in fact, dozens of the "rubbers" and "inhalers" were in attendance. One could almost

imagine that St. JOHN LONG was the eldest son of a Peer, for the law of primogeniture has certainly been most favourable to his interests.

#### ELECTION OF CORONER.

WE abstain from publishing any report of the late contest for the office of Coroner, or from making any further remarks on the subject, than are to be found at the conclusion of our preface, because the number of qualified votes is not yet ascertained, and it is doubtful whether the issue will not be made the subject of discussion in the COURT OF KING'S BENCH.

*Medico-Chirurgical Transactions.* Vol. XV, Part II. Longman. 1830. 8vo. pp. 451.

OF the three articles contained in this part, the first only, "On the anatomical characters of some adventitious structures," by Dr. Hodgkin, will require any detailed notice. After observing that he has for some years "enjoyed the opportunity of examining a great number of these structures, and that his attention has been particularly directed to the investigation of certain anatomical characters which arrested his attention, and appeared to indicate general laws of formation pervading the whole class," Dr. Hodgkin proceeds to speak of the accidental serous membranes which occur in the form of cysts. These cysts, exclusive of true hydatids, or acephalocysts, (of which, however, he gives no definition,) he divides into two kinds, simple and compound, or those which have, and those which have not, the power of reproducing other similar cysts within their cavity. On the former of these, of which the vesicles observed in the choroid plexus are perhaps the best specimen, Dr. Hodgkin "has but little to offer;" on the latter he has spoken much more fully:—

"Cysts of this kind, like those of the preceding class, are found in different parts of the body, but they are by far the most frequently met with, acquire the largest size, and present the greatest variety of appearances, in the neighbourhood of the uterus, but more especially in the ovaries and

the folds of the broad ligaments."—pp. 275, 276.

The parietes of these cysts are often "rather fleshy, or coriaceous, than membranous, and their internal surface is always more or less thickly covered with tumours or elevations, varying in size and shape, from flattened and scarcely-projecting vesicles, to complete cysts, filling up the whole or a large portion of the primary cavity. These secondary cysts are covered by the reflected lining membrane of the primary one, and are often filled, not merely by a serous or mucous fluid, but partly by tertiary cysts, arising in a similar manner from their internal surface, and covered also by a reflection of their lining membrane. These tertiary cysts sometimes cause, by their further increase in size, the rupture of the secondary ones, which then "bear a considerable resemblance to mucous follicles on a large scale, and appear to be the principal source of the very copious and rapidly produced mucous secretion, which is a characteristic feature in many cases of ovarian dropsy." After the cysts have been thus ruptured, and still more after the occurrence of inflammation in them, it is very difficult, or even impossible, to trace the original structure of the part. The secondary cysts are either pyriform, or somewhat orbicular, or of irregular shape, with a broad and flattened base. In the former case—

"It sometimes happens, that the number of cysts forming the cluster is so great, in proportion to the space which they occupy, that, like trees too thickly planted, they interfere with each other's growth. Their development is more or less limited to an increase of dimension in length. Yet as their free extremities are allowed to diverge, we sometimes find the slender peduncle gradually dilating into a pyriform cyst. At other times the dilatation does not take place till near the extremity of the peduncle, and then produces a cyst more nearly resembling a grape or currant. At other times no dilatation takes place, probably from the cavities having been wholly obliterated. These elongated productions sometimes become highly vascular, and, in the defect of an internal secretion, contribute largely to that which occupies the sac into which they project. Sometimes, on the contrary, they are very feebly organised, and appear ultimately to lose their vitality, in consequence of the kind of strangulation which they receive at the narrow neck by which they are attached to the containing

cyst. It would appear, that the pedunculated cysts and filaments which have thus lost their vitality, are a pretty frequent source of irritation to the serous membrane reflected over them, which constitutes the containing cyst; the product of the inflammation thus excited is of the inorganizable kind, and often forms a thick and grumous substance, which sometimes may be washed out from the bunches of filaments, but at other times these come away with it, in the form of shreds. The broad and flattened cysts appear to produce a circumscribed and more or less considerable thickening of the parietes, rather than a prominent tumour covered by a reflected membrane; they constitute, however, perfectly-shut cavities, acquire at times a considerable size, contain, in some instances, a serous, and in others a mucous secretion, and produce in their parietes inferior orders of cysts, having, like themselves, broad bases and flattened forms. From the extent of their bases, the secondary cysts in this variety occupy proportionably a much larger space on the internal surface of the containing cyst, and by their development, although they increase its size, they seem more completely to encroach on its particular cavity. In cutting into a tumour composed of this form of cysts, we may find, it is true, several cavities of considerable size, but we shall probably not find the greater part of the fluid collected into one particular cavity. Hence, in this variety of ovarian dropsy, fluctuation is often obscure, and the relief afforded by paracentesis only partial and trifling."—pp. 282—284.

Although the three forms described are generally distinct, yet they may all occur in one primary cavity.

The enormous size to which these cysts often attain when seated in or about the ovaries, Dr. Hodgkin attributes to—

"The obvious fact, that the system on which, in the case of ovarian dropsy, these cysts are implanted, is naturally disposed to obey a stimulus which requires an increased supply of nutritive matter, and which gives rise to a proportionably rapid growth; to the abundant supply of blood which the parts habitually receive; and thirdly, to the position of these parts situated in the abdomen, and their consequent exemption from all pressure or restraint calculated to limit their development. This last point appears to merit an additional attention from the suggestions which it excites in relation to the operation of paracentesis for the relief of this form of dropsy. As long as the distress and inconvenience of the patient will allow us to defer the operation of paracentesis, it is doubtless desir-

able to do so, since even the pressure which the full sac itself is able to exert on its contents, must have a tendency both to diminish the rapidity of secretion, and retard the growth of the inferior order of cysts. It is well known, that the oftener the operation has been performed, the shorter is the interval which elapses before a repetition is required; and in the course of a very few weeks a quantity is produced as large, if not larger, than that which had been many months in accumulating prior to the first operation."—pp. 287, 288.

Passing over those tumours to which the name of "encysted" has in general been especially applied, and the contents of which are often as different from the natural textures of the body, as what he has especially termed "heterologue formations," and certainly more so than those of the serous cysts, Dr. Hodgkin proceeds to the consideration of scirrhus, fungus hæmatodes, and melanosis. All these adventitious structures he considers as contained within particular sacs analogous to the serous cavities just described, and regards the radiating or cellular septa, so frequently observed in them, as the parietes of the secondary cysts.

"If," says he, "we carefully dissect down to the surface of one of these tumours, we shall usually find that it has a capsule or covering, which has, I believe generally been supposed to consist of the altered and condensed cellular membrane of the parts which have given way before the growth of the tumour. This idea is probably correct with respect to the unequally thick external part of the capsule; but if we dissect carefully, and examine those tumours in which the process of decay has either not commenced, or has made very little progress, we shall find that surface which is next to the mass of the tumour, more or less smooth and even, and on raising it we find that it is reflected over one or more somewhat pyriform bodies, attached by a base, which is generally narrow and peduncular, to some part of the circumference of the inclosing capsule. Unless the tumour is very small, it is much more common to find several rather than a single body of this kind, and as there is often little, if any, fluid intervening between them and the inclosing capsule, their form is somewhat modified by their mutual pressure. Sometimes, though more or less closely applied to each other, these pedunculated bodies are perfectly detached at their sides, and may, consequently, be readily traced to the point which forms the common origin of their peduncles. At other times, these bodies are so adherent

amongst themselves, and the membrane covering them is so tender and delicate, that without very great care the arrangement of their structure may be overlooked, in consequence of the pedunculated bodies being broken or torn through in a different direction from that to which their mode of formation would naturally dispose them."—pp. 295, 296.

These appearances cannot be shown by a simple section, (the usual mode of examining such tumours,) according to the direction of which, the cut edges of the cysts will appear as cells more or less irregular, or as radiating lines. The same causes, however, which have been mentioned as obscuring the structure of the serous cysts, will of course operate, and even more strongly, in confusing that of the solid tumours in question; the external or enclosing sac also is frequently ruptured, and the contained substance then shooting forth and growing with much greater rapidity, becomes of a softer consistence, and much more irregular texture.

The same strangulation of the pedicles of the secondary vesicles which we have mentioned as occurring in the serous sacs, according to Dr. Hodgkin's opinion, also takes place in these tumours, and is the cause of that central softening or decay which has been by some writers considered as peculiar to them, or at least to one form of them,—fungus hæmatodes.

The tumours in question, Dr. Hodgkin considers as essentially new formations; he admits, however, that the surrounding structures, more especially the cellular membrane, by a kind of sympathetic action often degenerate, or are converted into "a substance in some respects resembling that of the original tumour," though wanting that structural arrangement by which the latter is characterised. With regard to the term "malignant," he confesses himself equally unable with other writers on the subject, to give an exact definition of the tumours or morbid growths to which it is applicable, and therefore merely enumerates the principal characters of those which are most commonly thus designated; admitting at the same time that these characters are by no means certain or constant, and that any one or more of them is often wanting, and may accompany other non-malignant diseases:—

"Hence," says he, "arises the difficulty, not merely of composing a concise verbal definition of the term malignant, as applied to the tumours in question, but also in many cases of drawing the line in actual practice. For my own part, I should, in examining a tumour in the living subject, be in general disposed to suspect what has been called malignancy, whenever I could detect indications of the structure which I described accompanied with alteration of the surrounding structures, and in its origin referable to some external violence, or to a pre-existing indolent tumour. These suspicions would be proportionably stronger if the tumour in question occurred in a part known to be rarely, if ever, affected with that non-malignant and well-defined form of tumour which, in common with those of a malignant character, distinctly possess the structure alluded to; my suspicions would be progressively converted into absolute certainty in proportion as the other symptoms, previously detailed, unite themselves to those which I have assumed as presenting themselves in the suspected tumour. But suppose the tumour to have been removed from the body, and that a question as to its malignancy has been started. In the first place, I should consider some traces, however slight, of the structure which I have described existing in some part of the morbid growth, as a *sine qua non* to the character of malignity; hence the importance of having the whole, or a very considerable part, of the tumour submitted to our examination, and, if possible, that part which constituted the original formation should be contained in the portion selected for examination. This point being ascertained, we may, I believe, pronounce on the malignity of the new formation with a confidence proportioned to the degree to which the new growth deviates from the natural structures of the body, but more especially from the serous membranes. The spontaneous death of some internal part of the tumour, in consequence of the strangulation of some of the pedunculated bodies which compose it, is not alone a proof of malignity, but I have little doubt, that the influence which this change exerts, strongly contributes to induce a malignant character in the tumour. The degree of integrity or degeneration of the surrounding natural structures will also materially contribute to decide the question."—pp. 319, 320.

In speaking of atheroma in particular, Dr. Hodgkin observes:—

"The prolongations of indurated cellular membrane, proceeding from the tumour into the surrounding adipose substance, appear to have been considered as prolongations of the radiating lines observ-

able within the essential part of the tumour, and to have been regarded as a part of the scirrhus structure itself; in fact, as fibres of the disease on which its re-appearance, after an operation, mainly depends. For my own part, I very much doubt whether this altered cellular membrane itself really possesses any thing of the malignant nature, although I can easily conceive, that the tumour by which the disease makes its renewed appearance, may have taken its origin in the course of one of these indurated prolongations left in the surrounding structures. I believe this circumstance is to be explained in the following manner:—In dissecting away the fat from the principal part of a scirrhus tumour, I have had occasion to notice these prolongations of cellular membrane, and in doing so I have observed very small and delicate pedunculated cysts, some of which scarcely exceeded the size of a pin's head, dispersed upon the aforementioned cellular membrane. It is to the development of one or more of such cysts, rather than to the altered cellular membrane itself, that the new tumour is to be attributed."—p. 326, 327.

We are not aware that these cysts have been noticed by any other writer. Their existence is, however, interesting rather in a pathological point of view, than as affording any practical inference; for supposing them to be in every case the cause of the relapse, still they can only be removed by the excision of the diseased bands of cellular tissue to which they are attached, so that the method of treatment remains precisely the same.

Under the head of fungus hæmatodes, or "fungoid disease," as the author prefers to call it, in order to avoid ambiguity, and to include its other denominations, we find nothing particularly worthy of notice except the following statement relative to the formation of the tumours:—

"In this disease, the secondary cysts, which are often of large size, generally become filled with a material which at first bears a considerable resemblance to tender or feebly coagulated fibrine or plastic lymph. Into this substance new vessels speedily shoot; but being neither susceptible of perfect organisation, nor calculated to remain inert and dormant, it speedily, but gradually, loses its vitality, and, like other transparent parts in which such a change is effected, gradually becomes opaque, and bears, in consistence and appearance, a close resemblance to the substance of the brain of a child: hence the terms, cerebriiform bati-

cer, encephaloid tumour, and medullary sarcoma."—pp. 335, 336.

As far as we know, no other anatomist has described the appearance here mentioned, and it is to be regretted that Dr. Hodgkin has noticed it in so slight a manner.

With the account of fungoid disease, the paper is concluded, that of melanosis being deferred to some future occasion. We cannot close our observations on this instructive and valuable paper, as it certainly is, without expressing our regret at the want of arrangement, and the careless and obscure style, which distinguish it. Some parts of the communication are almost unintelligible.

The substance of the second paper, which is headed "Observations on the statement made by Dr. Douglas of Cheselden's Improved Lateral Operation of Lithotomy, &c., by J. Yellowly, M.D.," F.R.S., may, we think, be comprised in a few words. The operation in question was essentially the same as the modern lateral one, consisting in cutting down to the groove of the staff and opening the bladder, by making an incision along it through the membranous part of the urethra, and the prostate gland. Dr. Douglas, however, by some strange misunderstanding, thus describes it:

"His knife first enters the groove of the prostrated or straight part of his catheter, *through the sides of the bladder immediately above the prostate*, and afterwards the point of it continuing to run in the same groove in a direction downwards and forwards, or towards himself, he divides that part of the sphincter of the bladder that lies upon that gland, and then he cuts the outside of one half of it obliquely, according to the direction and whole length of the urethra that runs within it, and finishes his internal incision, by dividing the muscular portion of the urethra on the convex part of his staff."—p. 346.

Notwithstanding the *prima-facie* improbability of this account, and the inconveniences and disadvantages of such an operation, which, as Dr. Yellowly observes, "make it difficult to believe that it was ever actually performed," it was really copied by several authors, and among others by John Bell, who, in his principles of surgery, gives it as the description of Cheselden's final and improved method of operating—an error the more remarkable, as it is not even mentioned

by Cheselden himself in any of the editions of his works. The object of Dr. Yellowly therefore, was to point out, and correct, this error, which he has satisfactorily done; in truth he has adduced a superabundance of proofs and arguments, and has thus prolonged to thirty pages a paper which might, we think, have been very well comprised in ten.

An analysis of the third paper entitled, "Pathological Researches on Inflammation of the Veins of the Uterus, with additional Observations on Phlegmasia Dolens, by R. Lee, M.D.," was given in THE LANCET (No. 323), shortly after it was read at the society; we have therefore, on the present occasion, only to extract the following case of "Phlegmasia Dolens in a Male," observed by Mr. C. Hutchinson, and added, together with another of less interest, in the form of an appendix.

"Mr. B. lately returned from the Isle of France, where he had resided upwards of twenty years, received a blow upon his right shin, immediately over a branch of the saphena vein, by a small piece of timber accidentally falling upon it. The scar is very slight, though the injury and its results appear to have been severe, and the patient states that the accident was followed by considerable swelling and inflammation all over the limb, and that the abraded surface was very long in healing. Mr. B. says he first felt pain in the direction of the upper third of the saphena before it actually dips to unite with the femoral vein. The whole leg and thigh soon became enlarged and inflamed, the former partly edematous; and although the patient states the disease to be slowly on the decline, yet the enlargement of the thigh and leg still continues, and he has pain from the groin to the heel and sole of the foot, principally in the direction of the branches of the saphena, with a slight blush of redness over the fore part of the leg, where the original injury was received; but while the member is kept in the horizontal position he is nearly free from pain.

"I have traced the upper portion of the saphena vein, and find it to be a complete ligamentous cord for eight or ten inches, but the femoral vein seems to me to have hitherto escaped the diseased action. The patient has no pain or uneasiness within the pelvis, and his general health is good."

—LAVINIA M. D. D.

## UNIVERSITY OF LONDON.

## ENTRANCE FEES TO THE MEDICAL CLASSES.

*To the Editor of THE LANCET.*

University of London,  
Sept. 22, 1830.

SIR,—In a weekly medical Journal of the 11th inst., a statement appeared on the credit of an anonymous correspondent, professing to show that the expense of medical education in the University of London was one-half greater than in the other London schools.

This statement is erroneous in almost every particular; and it is most injurious to this institution, because the cost is a circumstance which influences the student very powerfully in the selection of his school. A letter authenticated by the signature of one of the medical professors was therefore sent to the editor of the journal in question, correcting the mis-statements in his journal; instead of inserting that letter, the

editor has contented himself with giving notice that he has referred it to his anonymous correspondent, and will recur to the subject in a future number. In the mean time the error is propagated uncontradicted.

The following statement shows the expenses of the University, and of one of the most considerable of the London hospital schools, from which the others do not materially differ.

That it may be of some value, it contains not only the *fees* but the *hours of instruction* given for those fees: for nothing is so vague as the term *course*; it may mean one month or twelve months of instruction; it may consist of a lecture once a week, or of one every day. The fee I have selected for comparison is that for a perpetual pupil; a thing as well known here as in the other schools. I assume that at the other London schools the lectures continue from the 1st of October to the end of April, as they do at the University, without any other interruption than a day or two at Christmas and Easter.

	London University.		Hospital School.	
	Hours per Week.	Perpetual Pupil.	Hours per Week.	Perpetual Pupil.
Anatomy *	11	£ 10 0 0	6	£ 10 10 0
Physiology	2	4 10 0	2	3 3 0
Dissection†	—	9 0 0	—	10 10 0
Surgery	2	4 0 0	3	5 5 0
Practice of Physic	5	9 0 0	3	8 8 0
Chemistry	5	10 0 0	3	8 8 0
Midwifery	5	7 0 0	6	10 10 0
Materia Medica	5	9 0 0	2	4 4 0
Botany	5	4 0 0	—	0 0 0
Matriculation Fee	—	2 0 0	—	0 0 0
	40	68 10 0	25	60 18 0

\* The course of anatomy at the University is given jointly by Professors Pattison and Bennett, at separate hours daily, and the pupils have a right to attend both professors for one fee.

† The demonstrator at both institutions gives instruction at intervals for several hours each day.

It is true that this does not include the extra fees paid by students not nominated by proprietors; these fees cannot exceed 4l. 10s.; and as there are 1700 persons entitled to that privilege, it is easy to procure a nomination.

Thus, it appears that in place of the instruction being 62l. 1s. at the London University, and 46l. 4s. at the other London schools, the difference is only 7l. 12s.; but the pupil receives one-half more time from his teachers at the University than he does

at most of the other schools; so that by dividing the sum by the time, the expense of the University is 1l. 15s., while that of the other schools is 2l. 8s.

That you may ascertain the accuracy of the above statement of the University fees, I inclose a copy of the notice of the lectures, just published. I am, Sir,

Your obedient servant,

A PROFESSOR IN THE MEDICAL SCHOOL  
OF THE UNIVERSITY OF LONDON.

## UNIVERSITY DIPLOMA. — APOTHECARIES' HALL.

*To the Editor of THE LANCET.*

SIR,—As the commencement of another medical campaign approaches, every member of the medical profession who possesses the proper feelings of ardour in its pursuit, and interest in its welfare, must look to the numerous sources established for the diffusion of knowledge with the utmost anxiety, to ascertain the degree of improvement in the method, or extension in the matter, of the various subjects proposed by the professors in their different announcements.

The University of London has not been behind-hand in publishing its detail of the intelligence to be acquired within its walls; but notwithstanding the reduction the directors have made in the fees of admission for pupils, which clearly indicates the conviction they feel of having on former occasions overrated the value of their establishment as a seat of medical learning, they have introduced into their paper an arrogant appeal, of such a self-important and charlatanical nature, that while it must tend to place the judgment of the management in a very questionable position, proves their want of correct information on the subject on which they have chosen to hazard opinions, and offer suggestions.

In this age of refinement and extension of literature, in which distinctions of learning are sought for with avidity, there will be found a large proportion of individuals anxious to possess the M. Med. et Chir. U. L. so temptingly displayed in the prospectus of the University; but the intrinsic value of these empty, unauthorized, and presuming titles must still be left to the appreciation of those immediately concerned. I trust and believe, the profession possesses too much intellect to allow the younger aspirants to become the dupes of the machinations of their vaunted sagacity.

I presume it is fair to infer, that the quotations from "the report of the *Faculty of Medicine*" would not on this occasion have been promulgated in the University advertisement, had not the managers entertained the views therein contained; therefore they must hold themselves amenable to observations arising from the publication of opinions clothed in the authority of their institution. After expressing the opinion, that "until the University can give the physician's degree, *not many* of those destined for that branch of the profession can be expected to take any considerable part of their education in its medical school," it is stated—

"Under the appellation of general prac-

tioners are included *two distinct classes* of medical men. One of them consists of practitioners who hold a highly-respectable rank in the profession, who have devoted much *time, labour, and money*, to their professional education; men possessed of *some* attainments in the collateral sciences, and who, practising their profession in a liberal and scientific spirit, have the highest claim to the confidence of the public. *Another* class, bearing the same appellation, consists of those who have acquired the right to practice by possessing *only the minimum* of knowledge by which the license can be obtained, earned by the *smallest possible expenditure of time and labour*, and who have consequently very imperfect professional attainments."

The attempt to divide the body of general practitioners into two classes, is absurd; and not less so is the forced distinction on which this division depends; there must in all professions be members who will attain elevated stations by the display of superior acquirements, address, or connexions; but when an equal degree of study is required of all candidates for a certain testimonial of competency, it is too much to hear a party, for the purpose of puffing itself and the establishment to which it belongs, cutting and dividing, and venturing opinions on the maximum or minimum of knowledge acquired by the possessors of a diploma, to obtain which, the legislature has required through its delegates a fixed amount of qualifications: it is true, in medicine, as in every other science, that while some shine as bright ornaments, others are deficient in clearness of intellect, or have been careless of the valuable opportunities offered them of improvement; and having obtained a mediocre position, are content to pass their lives without an effort to push on to the post of honour: but why are the general practitioners alone selected for division and subdivision on this account? when the same state of things is notoriously observable in the higher grades of physician and consulting surgeon.

Although "the public possesses so little knowledge of the details of a medical and surgical education," has the council of the University any honourable or candid object in view, in insinuating that the general practitioner is unworthy the confidence reposed in him, and that if his system of education were exposed, that confidence would be at an end? Certainly not; the only details with which the public are not acquainted, are of a nature little calculated to afford them any particular degree of pleasure; and therefore they are not commonly made the topics of general conversation, nor would they desire them to be so; but as there are few families who have not a medical man as

one of its members, it is quite clear they possess the means of arriving at a sufficient degree of judgment and penetration, to protect them from the evils against which they are so beneficently cautioned; and so far from the "duties of the profession" being commonly confided, without inquiry, to any one calling himself a general practitioner, I know no subject more deliberately canvassed, than any change of a medical attendant, or the selection of a physician or surgeon, when a consultation is deemed desirable.

I was at one time disposed to read with great regret the many severe observations that were passed on the system of the London University by the majority of the medical press, and to attribute to prejudice and interested motives, the little disposition which was manifested to take a favourable view of the measures of that establishment; but now I am compelled to retract, for the council, without the least control over the legislature of medicine, being, in fact, the mere organ of a set of literary speculators, who dispose of information for certain sums of money, has thought proper to publish impertinent and uncalled-for observations on the class of individuals by whom they confess their school is chiefly supported, to question in a positive manner their attainments, and offer the University as a corrective of all their defects: and what has this University done towards the improvement of the general study of medicine? I answer, nothing, worse than nothing; for that valuable time which might have been profitably employed, has been passed in turmoil and dissensions, calculated to destroy all confidence, and render most questionable the stability of the establishment, in the opinion of its best supporters and warmest advocates.

I cannot close this subject without directing the attention of the profession to the rules and regulations of the Society of Apothecaries; the unceasing endeavours of the Court of Examiners to effect a progressive increase of knowledge in the candidates for its diploma, deserves the warmest applause and support; the legislature has confided to the judgment of its members, a degree of power which they have exercised with considerable foresight and effect; the regulations which they have framed from time to time, must have resulted from deliberations conducted with care, independence, and intelligence; their demand on the pupil for information, has not even increased in so sudden a manner as to have the effect of overwhelming his mind by too great an exercise of his intellectual faculties; but he has been gradually drawn on, from one acquirement to another, until it may fairly

be expected that the future apothecary will bid defiance to the taunts and sarcasms which have of late been unceasingly and lavishly hurled at him, for his supposed deficiency in classical and professional attainments. The members of the Court of Examiners have been laudably and perseveringly endeavouring to place that portion of the profession over which they have been permitted to exercise authority upon a firm basis of respectability; and judging from the manifest improvement that has already resulted from their exertions, there can be no doubt, that as their plans become more fully developed, and their system of education assumes a still more academic character, that an unspeakable benefit will be conferred on the practitioner and the public: it becomes us, therefore, to give them our confidence and warm approval, as their endeavours are doubly enhanced by the impossibility of connecting their proceedings with motives of an unworthy, ungentlemanly, or mercenary description; the whole train of their thoughts has been directed to the improvement of the profession generally, and although some may have felt disposed to quarrel with them, still the majority of thinking and intelligent individuals will allow them full justice for their stability of purpose, and they will rise in the estimation of competent judges, as a tribunal working as large a portion of general usefulness in their department, as the limits of their charter allows them the power of effecting.

I am, Sir, your obedient servant  
And constant reader,

APIS.

Sept. 21st, 1830

DR. ALEX. THOMSON AND PROFESSOR  
PATTISON.

*To the Editor of THE LANCET.*

SIR,—I hope you will do me the favour to state to Professor Pattison, who pretends to a contemptuous ignorance of "a Mr. Thomson," that *Mr. Thomson* is the son of Dr. A. T. Thomson, the professor of Mat. Medica of the London University, a person who disdains to enter into any public controversy with one who can so far forget himself as to pretend ignorance of the man to whom he has sent the enclosed letter, and whom he has himself been in the habit of employing as his assistant in the few operations he has happened to perform at the London University Dispensary. This Mr. Thomson is a Bachelor of Medicine of Cambridge, and is practising in London.

under the sanction of the College of Physicians.

I am, Sir,

Your obedient servant,

ALEX. THOMSON, M. B.

Letter of Mr. G. S. Pattison, late Professor of Anatomy in the University of London, to Alexander Thomson, M. B.

"8, Old Burlington Street,

"Aug. 13th, 1828.

"My Dear Sir,—In compliance with your request that I would furnish you with my opinion as to your qualifications for filling the office of Curator to the University of London, I now address you.

"It is impossible for me from my own observation to testify as to your skill in the preservation of anatomical preparations, having never had an opportunity of examining any of the preparations which you have put up. You have, however, I believe, presented to the council specimens of botanical, and other subjects of natural history, prepared by yourself, from which they will be able to judge for themselves of your skill and neatness in preparing such objects.

"Although I am not qualified to certify specifically as to your qualification for the preservation of anatomical preparations, I can speak without hesitation of your talents, your industry, and your zeal, in the acquisition of knowledge. The course of your studies has been most extended; and the manner in which you have devoted yourself to the study of natural history, and the progress you have made in the different branches of it, should certainly qualify you in a very eminent degree for the discharge of the more important duties of the situation which you solicit.

"I remain, my dear Sir,

"Yours most truly,

"GRANVILLE SHARP PATTISON."

## NON-MEDICAL CORONERS.

To the Editor of THE LANCET.

SIR,—Duly appreciating the advantage which the public would obtain by your success in your present contest for coroner, I offer you the following examples of the insufficiency of non-medical persons to fill an office so pregnant with good or evil to the public, according as it is well or ill discharged.

A few months ago, a poor man named Winney, a convict, was found dead with his throat cut, in the Gun Wharf at Portsmouth, where he had been working. The Coroner afloat, presuming erroneously on his right over convicts as clients, because forsooth they sleep on the high seas, overstepped his jurisdiction, and held his inquest on the body. The medical witnesses directed the jury by their evidence to find a verdict of suicide, which was recorded accordingly by the Coroner. Some of the convicts, more shrewd (say professionally so), than either the men of science or those who ought to have skilfully judged of the propriety and justness of that evidence, judiciously reasoned thus: Winney's time of duration is nearly expired, and he lends us money upon terms, surely he could not have had any motive to have committed suicide. These rumours reached the ears of the intelligent Mayor, Edward Carter, Esq., who directed the Borough Coroner to hold another inquest, and take the evidence of a skilful surgeon touching the death of this poor man. The surgeon on an examination found a fracture of the skull which no man could have given himself; found the throat so much lacerated, that the vertebrae of the neck were partially severed, and, what was of much consequence, observed, that the small effusion of blood proved that life was almost destroyed by the blow on the head, before the throat was cut; while the unschooled hands, showed in corroboration that the unhappy man could not have been his own executioner. A revised verdict was found of wilful murder against a person of personage unknown. Two men were subsequently executed on the most undeniable proofs for this offence, who had nearly been let loose on society to commit further murders, by the admission of incompetent testimony.

In another case within a few months another attorney coroner holds an inquest on a case of infanticide (so alleged), and a verdict that the child was born alive was recorded, and wilful murder against some unknown person. Well, this would not have been so very extraordinary had not all this scientific examination and discovery have been effected, without calling in the aid of any medical man whatever; who, we affirm, could alone have been competent to have judged of this extremely nice and intricate point. We will not say *Ab uno disce*. But we will give another specimen.

The same coroner held his jury inquisition on the body of some person, whom in his infallibility of science he directed the jury to find a verdict of "died of apoplexy." True, most erudite Theban, but was this apoplexy of the "visitation of God," or induced by poison administered? Who could inform him and the jury of this point but a

medical man, who was not called in on the occasion?

I am Sir,

Your constant friend,

PHILANDER.

Portsea, Sept. 17, 1830.

REFLECTIONS ON THE FOES OF TRUTH, AND  
THE ENEMIES OF MEDICAL CORONERS.

"They may exult over the repression of petty talents; these are but the receding waves repulsed and broken for a moment on the shore, while the great tide is still rolling on and gaining ground with every breaker."

"The people by-and-by will be the stronger."  
Byron.

To the Editor of THE LANCET.

SIR,—With the views and opinions of your correspondent G. D.\* I do entirely concur; and were repetition necessary, I could add the result of my experience in confirmation of his own. Like him also, I take my motto from the man whose sublime genius has adorned the cause of liberty with the most splendid gems of poetry; not because he has done this only, but that to the grandeur of the poet he has added the presence of the seer. For why may we not apply to passing events these passages, which, to the language of freedom adds the inspiration of the prophet? That we may not do so, I see no reason, because, the weak but well-meaning friends of your late opponent endeavoured to deride public opinion by sneeringly calling it the majesty of the people: it is the majesty of the people, and is of a much more enduring dynasty than any other. Had the judgment of those friends equalled the desire of success, they would not have committed their understandings by so sorry a jest at the expense of good taste and truth; nor would they have ridiculously confounded cause and effect, by supposing that the advocates of the people were the sole causes of the people contending for their rights; they would have known that your addresses were not the excitement to the measures which, in their childish terror, they deprecated as hostile to good order, and desecrated by describing as dangerous to the state! They would have known that you were the organ of the people, echoing their sentiments,—not appealing to their passions: they would have known, "that in their opinions, the people are seldom wrong; and that, in their sentiments, they are never mistaken." They would have known that both the

opinions and sentiments of the people were in favour of intelligence and independence; and opposed to mental imbecility, moral cowardice, and the absence of those qualities which grace the scholar, the citizen, and the man. It may add to the mortification of those who traduced you, and slandered the people, that although the "march of mind" may be retarded by the disposition of vulgar minds to vilify what they cannot comprehend, it cannot retrograde, and always starts whence it was detained.

The letter of another correspondent, "a Licentiate of the London College of Physicians,"\* although it requires no comment, contains a statement which demands a contradiction. It is not true that Physicians have the power to inflict a fine for refusing to meet them: they are said to have an obsolete law, which expresses that a penalty is leviable for refusing to compound their prescriptions. I believe, however, that there is not an individual of the much-abused class of general practitioners so base and "pigeon-livered" as to comply with the law from apprehension of the penalty. Let the general practitioners enfranchise themselves from an irksome and degrading thralldom, by unanimous co-operation, and while they leave untouched the claims of the exclusives, let them fearlessly assert their own.

I remain, Sir,

Your faithful servant,

WILLIAM AUGUSTUS WALFORD,  
Speldhurst Street, Burton Crescent.

P. S. The part taken in the late contest by Sir W. Blizard and Mr. Headington is the subject of indignant remark, nearly throughout the profession. The degradation of those men was already complete, and needed not this last act to render it irretrievable. For Sir William it may be urged in extenuation, that to a naturally weak intellect is added, the infirmity incident to extreme old age: but what shall we say for Mr. Headington? Although the first portion of the same excuse may be pleaded for him, yet the remaining moiety of the apology will not avail him; for notwithstanding Time has thinned his flowing hair, and he has arrived at that period of life when men are rarely converts to more liberal opinions than they held before,—an age at which a sordid bigot never becomes a proselyte to toleration and improvement—an age at which the heart never glows with generous sentiments unseen before; although he is a miserable example of manhood without spirit, he is not yet so humiliating an instance of age without experience as his dotting colleague Sir W. Blizard.

\* Vide LANCET, page 924, Vol. II. 1829-30, on the grades of the medical profession.

\* Vide page 925, Vol. II. 1829-30, of LANCET.

Therefore in accounting for Mr. H.'s hostility, remember that he has for nearly a quarter of a century filled an office, which he must have vacated twenty years ago had his Whitechapel campaigns been under the surveillance of a medical coroner. Their confederate opposition on the present occasion is quite consistent with the acts of their whole lives, which have been spent in a little crusade against liberalism, which they have always described as "innovation." Who, therefore, can wonder that these worthy men should have acted as they did, when the return of a medical coroner would have placed this interesting couple in a light which would not only surprise their pseudo admirers, but also astonish the innocent creatures themselves! It is worthy of remark, that their combined efforts in favour of imbecility and corruption were the only affectionate intercourse they have ever been known to hold; for though joint foes to the "good cause," they have always taken different roads in their progression backwards: indeed they remind us of Rauceosanti and the Tenor—

"These two hated each other with a hate  
Found only on the stage;  
Sad strife arose, for they were so cross-grained,  
Instead of bearing up without debate,  
That each pulled different ways with many  
an oath,  
'Arcades ambo,' *id est*, blackguards both."

I shall anticipate any objection to the uncourtly character of the concluding line, in the words of Junius: "If any coarse expressions have escaped me, I am ready to agree that they were unfit for me to make use of, but I see no reason to admit that they have been improperly applied."

W. A. W.

#### RE-APPEARANCE OF THE YELLOW FEVER AT GIBRALTAR.

[From a Correspondent.]

I HAVE been favoured with a letter from Gibraltar, dated the 12th of August, of which the following is an extract:—

"The month of July has been unusually warm, and the heat at present continues very oppressive, the thermometer ranging as high as ninety degrees (Fahrenheit) in the shade. Some well-marked *sporadic* examples of the *autumnal bilious remittent yellow fever* have appeared, and given rise to apprehensions little short of those that existed previous to our fever of 1823 assuming its epidemic character. It is very remarkable that the Company of Sappers and Miners in the barracks on Hargrave's Parade, the locality where the first cases of the disease

discovered themselves is that year, &c., as yet, the chief sufferers; and have, during the last week, sent *eight cases* to hospital, four of which exhibit *yellow skin*, and other combinations of symptoms which mark this *Protean* form of fever; in consequence of which, his Excellency, the governor (General Sir George Don), has ordered this corps to evacuate their barracks, and to occupy the sheds on the neutral ground; but whether these cases are to be considered the presage of future evil, I know not; neither shall I pretend, at so early a period of the season, to offer an opinion, although, borne out by three or four other cases which have been admitted into the Civil Hospital, it would not, perhaps, be thought presumptuous in me to hazard one. However, something appears to be decidedly wrong at head-quarters; for Sir George has said, "that he cares not a *darn* for the opinions of any military medical man in the garrison! That they know nothing at all about the disease!" Whether we are to argue from this, that our principal medical officer (Dr. Farrell), "who," to use the words of Ben Jonson, "no sordid hope of gain, or frosty apprehension of danger, could turn a parasite to time, place, or opinion," has said anything hostile to the "importation" and "contagion" creed of our worthy General, I cannot say; but it is currently reported, and I believe it to be true, that the *redoubtable accoucheur* of the garrison has been summoned to head-quarters, to report especially on the above-mentioned cases! What opinion this *sage* has thought proper to offer to his Excellency continues a mystery, and is studiously withheld from all such plebeians as myself.

"A young medical officer in the garrison, who has been, not very remotely, converted by that most powerful of all agencies—the *talismanic wand of promotion*, asserts, in opposition to formerly-declared opinions, that none of these cases are yellow fever; but under what genus of disease he would wish to class them, he has not yet thought proper to make known. This gentleman is, indeed, one of those logical reasoners, the medical aim of whose conclusions it is not at all times easy to comprehend; yet, it argues, I think, with some show of reason, that his object is further to attract the sunbeams of the *bulambus luminaries* to a more concentrated focus on his *cubexa*, by which, probably, he supposes its cerebral structure might be warmed into a more brilliant and energetic display of ideas, in defending the visionary dogmas of these African worthies."

We refrain, for the present, from making any lengthened comments on the above extract, which, however, the importance of the subject would almost compel us to do, but will content ourselves quietly to await

the course of events; and should our next intelligence from Gibraltar discover the cases remarked on by our correspondent to have assumed an epidemic character, we most sincerely trust that the enlightened secretary for the colonies, General Sir George Murray, will immediately cause to be dispatched to that fortress, a few well-educated medical men of tried integrity, and possessing sufficient rank to prevent the repetition of such hole-and-corner work as took place at the close of the epidemic of 1828. We need not remark, because it is sufficiently known, that the gallant secretary above alluded to, caused to be instituted a board of inquiry into the origin of that epidemic; but owing to the interested motives of some of the members of that board, together with the prepossessions of others, the intentions of the gallant secretary had well nigh been frustrated; and frustrated they certainly would have been (for truth was most clearly not the object sought by the majority of the members of the board), had not the unbending integrity of Colonel Chapman and Judge Stowell, two of the members, protected the opinions of the obviously conscientious, from the insolent and ignorant, cross-examinations of two men, who, most unceremoniously, were foisted into the commission, as we have good reason to know, without the honourable secretary ever being consulted on the occasion. For our own part, we have no wish to see any further examination instituted into the origin of this fever; for we have long since considered all such fevers to be just as much the product of the soil as the potatoe; but it is just and proper, that so long as individuals are found arguing for an exotic origin of the distemper, that inquiry should be allowed to take place; and in such an inquiry it is most especially requisite that no persons who may be avowedly interested in support of this latter opinion should be permitted to interfere, without having, at all events, their designs and movements submitted to the most rigid public scrutiny.

---

MR. KING.

*To the Editor of THE LANCET.*

SIR,—If the editor of THE LANCET will appropriate a corner of his journal to the letter beneath, he will favour one who believes himself honest in the expressions of the sentiments it contains.

In No. 364 of THE LANCET, I was surprised and hurt to find that a meeting and consequent resolutions emanating from those of my fellow pupils then in town, too certainly proved that Mr. King had ceased to be attached to the school. To me, and I am sure, to the rest of the absentees, this

occurrence was perfectly unexpected and much deplored. We had never doubted that we should meet our very worthy and respected teacher in the ensuing season—that our acquaintance and connexion would be renewed but to be perpetuated—that the esteem, nay affection, which was so purely, so gratuitously offered, wanted only opportunities for its exercise to prove the force of its sincerity. This was founded on no blind adherence—there was no prostration of thanks; it was the most natural tribute of generous minds, an honest expression of their feeling offered to talent, urbanity, and strict disinterestedness. We all felt that when Mr. King joined us, we had a valuable accession; constant in his attentions, unwearied in his exertions, he smoothed difficulties, and pointed attention to matters till then unheeded. The necessity of perseverance was inculcated, the object to be attained was pointed out, and higher stimulus to exertion encouraged. His really valuable instructions were offered in the most unreserved manner, and in the most impressive form; and there are many of his pupils who will proudly acknowledge their value and importance, whilst they lament the suddenness of their deprivation. Whilst their attachment and esteem were freely, voluntarily offered, it will be matter of congratulation to both, that a reciprocity of feeling was engendered, which has been mutually acknowledged, and will be permanently recorded.

AN OLD PUPIL OF THE  
ALDERSGATE-STREET SCHOOL.

ON  
THE TOXICOLOGICAL RELATIONS  
OF THE  
SULPHOCYANIC ACID.

By W. B. O'SHAUGHNESSY, M.D.

IN the following observations, my principal object is to point out the peculiar circumstances under which the extreme sensitiveness of the meconic acid to the persalts of iron, may be rendered a *certain* test of the presence of opium in medico-legal inquiries. That further remarks on this subject are not entirely superfluous, is proved by numerous and convincing reasons. To these, however, I shall not now advert, as they will show themselves sufficiently and more appropriately as we proceed.

In the first place, then, I shall very briefly enumerate the chief chemical peculiarities by which opium and its solutions are distinguished.

I shall next consider the principal imitative actions which, taking place between other substances, interfere with the decisive character of the evidence thus detailed.

Finally, I shall notice the leading processes recommended by toxicologists for its detection, and either point out or explain how far each process is affected by the sources of fallacy which shall be described.

To many, I am aware that a recapitulation of the chemical constitution of opium is entirely unnecessary; but as there is at least an equal number to whom this repetition may be desirable, I shall proceed with it, though with the utmost brevity, and only so far as the chemical relations of the drug are toxicologically concerned. The two most remarkable ingredients of opium, are morphia and meconic acid, which exist together in the state of a neutral saline combination. The separation of the meconic acid from the solutions of opium, is easily effected by the agency of lead, with which it forms an insoluble compound, so that the addition of the acetate of lead to a solution of opium, causes an interchange of elements; the meconate

of morphia is decomposed, the insoluble compound of meconic acid and lead subsides, and the acetate of morphia remains in solution. If this meconate of lead be now subjected to a stream of sulphuretted hydrogen gas, the acid is set free, and may be obtained by filtration and subsequent boiling. This solution is now found to possess peculiar properties, it reddens litmus, and with the persalts of iron assumes an intensely red colour.

To this latter property of the meconic acid, toxicologists have justly directed their principal attention in their search for a method of detecting opium in complex admixtures; as if, however, to baffle the industry of chemists, it has long since been discovered, that the sulphocyanic acid and its salts possess the same action with the persalts of iron as the meconic acid, and that with an equal, if not superior delicacy; and, what is of the first importance, that the sulphocyanate of potass exists in the saliva, the bile, and other animal secretions. An evident source of fallacy thus presented itself,—if not in actual analysis, at least in the logical precision required in medico-legal testimony. Though lawyers have availed themselves of the notice taken of the fact, in works on forensic medicine, yet no attempt has been made to ascertain whether the sulphocyanate of iron might be formed at all during the process for detecting opium, and, if so, how the two salts (the meconate and sulphocyanate of iron) might be distinguished from each other.

To remedy this defect, I have applied the several processes recommended for detecting the meconic acid; first, to solutions containing the sulphocyanate of potass; and, secondly, to the animal secretions which are asserted to contain that substance. The results of these experiments I now communicate under the impression that they may be of some practical utility, both as far as regards the discarding of deceptive processes, and the further elucidation of one which has received the sanction of the most distinguished of all authors on the chemistry of poisons.†

† Vide Christison, p. 516.

Three modifications have been recommended in the application of the iron test to solutions suspected to contain opium. The first is the direct addition of the permuriate of iron to the fluid under examination; the second is the precipitation of the fluid by the acetate of lead, and the decomposition of the precipitate by the sulphuric acid; the third differs from the second essentially, in this decomposition being effected by the sulphuretted hydrogen gas.

To the first of these methods there exists one great and almost palpable objection, namely, that the saliva contains the sulphocyanic acid in combination with potash in such a quantity, that the addition of the permuriate of iron is sufficient to change it to a deep blood-red colour. It is strange, that though this fact has been long known, it has only been noticed in the most superficial manner by the recent writers on the detection of poisons. Thus Dr. Christison, speaking of the meconic acid and its effects on the persalts of iron, dismisses this fallacy in the following words:—"Only one other acid is so affected, namely, the sulphocyanic, a very rare substance." I have also often found evidence of the sulphocyanates in the mucous fluid remaining attached to the villous coat of the stomach, and it was more-over remarkable that this fluid had, in all these cases, an acid re-action on the litmus test. For these reasons I believe it will be admitted, that the direct addition of the permuriate of iron to a suspected fluid, can never afford satisfactory indications of the meconic acid.

The second modification of the process is also liable to some important fallacies. The acetate of lead, added to various organic fluids, while it precipitates the muriates, phosphates, &c., which they contain, also causes an abundant deposition of organic matters, especially albumen and casein. If to a precipitate of this kind strong sulphuric acid be added (in the quantity recommended by the proposer of this method of decomposing the meconate of lead), the fluid will, in a very short time, assume a reddish tint, not at all dissimilar to the meconate and sulphocyanate of iron. This effect is produced by the action of the sulphuric acid on the albumen attached to the metallic precipitate, an action first pointed out by Dr. Hope, the professor of chemistry in the University of Edinburgh, but never before (at least as far as I am aware) applied to the elucidation of difficulties in this department of analysis. Its importance is, however, by no means trivial, as it is concerned, not only in the search for opium, but in several other analogous investigations. On a late celebrated inquest, I was intrusted with a portion of skin for analysis, to which it was supposed some irritating

and deleterious liniment had been applied. On this skin, and the fluid in which it had been preserved, I instituted a series of experiments, so devised as to comprehend by their indications, arsenic, antimony, copper, silver, and the corrosive acids. The fluid reddened litmus slightly, and contained starch in solution, resulting from some particles of a poultice which adhered to the skin. Nitrate of baryta caused in this a white precipitate, which, when treated while moist, with the nitric and sulphuric acids, became of a reddish colour, inclining to violet, precisely of the same tint as minute portions of the iodide of starch assume in complicated mixtures. These phenomena strongly indicated the presence of hydriodic acid; but as the nitro-muriate of platinum was not affected by the fluid, and as, in subsequent experiments, I found the sulphuric acid to produce the same effect on several albuminous precipitates, I considered that a sufficient source of fallacy existed in these experiments, to render inadmissible any testimony founded on their results.

To the third process I have in the last place to advert; it consists in decomposing the supposed meconate of lead, by sulphuretted hydrogen gas. It is recommended by Dr. Christison, and I am happy to be enabled to add my feeble evidence in support of its great superiority over every other hitherto recommended. Its chief excellence however, Dr. Christison has omitted to mention, and which consists, in the first place, in its entire freedom from the fallacy of the reddening of albumen by the sulphuric acid; and, in the second place, in the necessary removal of every trace of sulphocyanic acid, or its compounds, which is perfectly accomplished by the washing of the precipitate as he directs. Nothing can point out more strongly than this, the value of minute practical directions as to the manipulation of toxicological analysis. In this instance, any sulphocyanate of lead which may have been formed, is dissolved away by the water employed in the ablation of the precipitate. Thus if the sulphocyanic and meconic acids be mixed together, and the acetate of lead be added, a precipitate falls down which, when washed carefully, and decomposed by sulphuretted hydrogen, affords the meconic acid. Again, if the fluid remaining after the precipitation be filtered, and tested with the permuriate of iron, it will afford the red sulphocyanate of that metal.

When I first commenced experiments on this subject, my object was to find out a method by which two red solutions of the same tint, one the meconate, and the other the sulphocyanate of iron, might be distinguished from each other. In the pure state this is easily effected by diluting both with distilled water, to a very light and

transparent degree of redness, and then adding a drop of an alkaline solution. The sulphocyanate immediately is bleached to a dead pale white,\* while the meconate becomes turbid, and deepens in its tint. Again, the colour of the sulphocyanate may be restored by the cautious addition of a solution of *chlorine*, while the meconate does not resume its redness under the same treatment. To these experiments, however, I do not attach much practical importance, as, in the first place, they require extreme attention to the quantity of the permuriate of iron employed in striking the original red colour, as a minute excess of the salt of iron completely obscures the distinguishing characters thus described. In the second place, various animal fluids interfere with the actions to a very troublesome degree.

In conclusion, I may observe, that my aim in the preceding observations, has rather been to collect together some isolated and scattered chemical facts, and to apply them to the purposes of this particular branch of analysis, than to advance any novel or peculiar opinions. At any rate, attention to these facts and explanations may contribute in some degree to prevent the confusion which might be occasioned on a cross-examination; by interrogatories respecting the fallacies attributed to the agency of the sulphocyanic acid.

27th September, 1830.

## ON THE HEART.

By WM. DOBSON, Surgeon.

SINCE the time of Harvey, the action of the heart has been founded on sensibility. Though this organ is supplied with nerves which endow it with the power of involuntary motion, yet it is conceived requisite that some stimulus should be applied to bring it into play; and however paradoxical it may appear, it is nevertheless true, that the heart will continue its action when removed from the body.

The motions of the heart are conceived to result from the agency of the blood in its cavities, acting either by some inherent stimulus in the blood, or by distending the walls of the organ. For a considerable period I have been engaged in examining the nature of the circulation, but other necessary engagements have prevented me giving publicity to my observations; and I

should not, at the present, have intruded into the pages of *THE LANCET*, but for the notice of two theories on the heart's motion, by Drs. Corrigan and Hope; hoping, however, by the promulgation of my observations, to assist in solving that important problem, "*the cause of the heart's stroke on the chest.*"

When opposite opinions are entertained by eminent individuals, we necessarily presume either that the question is so abstruse as to elude demonstration, or that their theories are deduced from false data. The latter conjecture I shall endeavour to prove is the case. It is imagined, then, that the heart requires some stimulus to excite it to motion. Not a more erroneous notion ever prevailed! It originated in the dawn of science, when the physiology of the nervous system was as imperfect as its anatomy was unknown. Such is the influence of the nervi sympathetici on the organ it supplies, that it not only endows them with the power of moving independent of the will, but it enables them to perform continuous alternate contractions and dilatations quite independent of every other material agency. I have alluded to a fact, that the heart will contract after its removal from the body; and I may adduce another equally valid in support of my position. Having introduced my hand into the thorax of a dog, I grasped the two vena cava, so as to preclude the entrance of blood into the heart. What was the effect? Why the action of the heart was still maintained! Though somewhat enfeebled, it continued to dilate and contract alternately and regularly. The circumstance, which seemed remarkably peculiar, was, the *diastole*, both of the auricles and ventricles, was apparently more energetic than the *systole*. In this experiment I witnessed the following phenomena:—

1. That, during the *diastole* of the ventricles, the heart was visibly augmented in size; and that, during the *diastole*, it was when the stroke against the side of the thorax occurred, not only the apex, but the anterior surface of the heart, impinged against the thoracic wall.

2. During the *systole* of the ventricles, the heart diminished in size, and receded into the thorax.

Remembering that, as taught in the schools, this stroke of the heart against the chest resulted from the aorta endeavouring to straighten itself, when blood was thrown in, tilting the apex against the chest. To obviate this effect I grasped the vena cava, and thus removed that attributed cause, but the phenomena occurred as before.

These experiments and observations were made at the least twelve months ago; con-

\* I may remark here, that so great is the influence of alkaline or earthy carbonates over the colour of the sulphocyanate of iron, that the addition of Thames water, in an equal volume, will decolorize a deep red solution of that salt.

sequently, previous to the publication of Dr. Corrigan's interesting essay.

Many other phenomena were also noticed. At some future period I hope to lay before your numerous readers a more detailed statement. Should these few remarks, however, be deemed of value, I shall feel obliged by their early insertion.

#### OBSERVATIONS

##### ON

#### SYMPTOMS ATTRIBUTED TO

#### CEREBRAL DISEASE.

*By FORBES WINSLOW, Surgeon.*

WERE the attention of medical men, says Sydenham, directed as much to the prevention as to the cure of disease, many of those deviations from the healthy condition now considered as the opprobria of our art would be prevented. Few in the present day question the truth of this observation. It is generally believed by those engaged in medical practice, that by a judicious management of the health of those constitutionally predisposed to particular maladies, the development of many of the diseases considered as incurable *by the profession* might be prevented. The practitioner, by *anticipating* disease, is thus enabled to prevent many of those organic affections, which when, developed, resist the united skill of the physician, surgeon, and apothecary. It is well known that consumption may be *prevented* by removing a patient phthisically predisposed, to a mild climate. The development of insanity may also often be prevented, by paying great attention to the moral and physical treatment of those who are hereditarily predisposed to this distressing disease.

The medical profession are much indebted to the late Dr. Gooch for his able disquisition "on the symptoms in children erroneously attributed to congestion of the brain." Dr. Gooch united with a profound knowledge of every branch of his profession great professional tact, which enabled him to discover with uncommon nicety, the legitimate causes of morbid action. Very few works communicate so much sound practical information as Dr. Gooch's last work on "Diseases of Females."

In the essay above alluded to, Dr. Gooch has endeavoured to prove that many of those diseases commonly attributed to cerebral congestion, arise from a deficiency of nervous power, and require for their removal not depletion but support. Consequently bleeding tends greatly to aggravate the affection and hasten the fatal tendency.

That great sanguineous depletion is not only injurious to young children, but very frequently the cause of an accumulation of water in the head, cannot be for a moment questioned. This *fact* is of great importance to the profession, for it is only from facts that we are enabled to deduce right conclusions.

By a series of experiments made by Drs. Saunders and Seeds of Edinburgh, they have found more or less of serous effusion within the brains of animals who have been bled to death, either from arteries or veins; and Dr. Kelly says, "Were it possible by profuse hemorrhages, to drain the brain of a sensible portion of its red blood, the place of this spoliation would be supplied by extra and intra vascular serum, and that *watery effusion within the head is a constant concomitant, or consequence, of great sanguineous depletion.*"\* I am indebted for the account of the following cases to a medical friend, Mr. Simmons, and as they prove the correctness of Dr. Saunders' experiment, I shall briefly narrate them.

CASE 1.—Susan A. *ætat* 5, of a delicate constitution, laboured under the following symptoms:—Great languor, unwillingness to move her head, to which she was constantly applying her hands, as if in great pain; the vision was indistinct, the pulse quick, but feeble, the bowels irregular. The medical gentlemen, judging from the symptoms that inflammatory action was going on, applied eight leeches to the temples, and ordered her bowels to be emptied by a cathartic composed of calomel and jalap. The following day the child was worse, the leeches having failed to relieve the supposed inflammatory symptoms. On the second day four more leeches were applied to the temples, and a blister to the nape of the neck, notwithstanding which, the child gradually grew worse, and on the sixth day died. Towards the latter part of her illness, she showed every indication of the existence of water in the head. On the post-mortem examination, a large quantity of serum was found in the ventricles. There was no appearance in the brain which would lead a person to believe that inflammation had at all existed previous to the child's death. The vessels of the brain were found unusually empty.†

CASE 2. This case, which was attended by the same medical man, resembled the above, both as regards the symptoms and the results, with the exception of a less quantity of serum being discovered after death in the brain.

\* Pathology of the Brain.

† This accords exactly with what Dr. M. Hall represents himself to have seen in the examination of those who have died under similar circumstances. —On loss of Blood. *Med. Essays.*

CASE 3.—Matilda H., *ætat.* 3, of a strumous habit, was attacked with great restlessness, pain in the head, and a quick but feeble pulse. The skin was of an ordinary temperature; the bowels were not confined. The eyes of this patient had that peculiar squint considered by medical men as a sure indication of the existence of water in the brain. The same medical gentlemen being called in, and fearing lest this case should prove fatal, called in Mr. Simmons, when they agreed in consultation to adopt a different plan of treatment. The patient was allowed a generous diet, and tonic and stimulant medicines were administered. To the surprise of both practitioners, neither of whom had anticipated a favourable result, the little patient on their next visit was considerably improved, and gradually recovered.

Were not the symptoms of the two unsuccessful cases aggravated by bleeding, and are we not warranted, reasoning from analogy, in supposing that the accumulation of the serum found in the ventricles of the brain after death, was the consequence of the great abstraction of blood, and not the cause of the supposed inflammatory symptoms? Dr. Marshall Hall has published some valuable remarks on the effects of loss of blood, which are well worthy the attention of every practitioner. Dr. Hall's observations on this subject coincide with those made by Dr. Gooch; for he says, "I have frequently known the effects of loss of blood, to be mistaken for inflammation of the brain." Do not let it be supposed that I wish to deprecate the use of leeches in affections of the heads of children; on the contrary, I think that when inflammation is known to be going on in any part of the head, abstraction of blood by leeches is the only effectual way of putting a stop to its progress. But there are cases, the symptoms of which greatly resemble those produced by inflammation, but which are caused by a deficiency of blood, by a want of nervous power in the system, and which are only to be successfully combated by supporting the patient.

"I have many times," says Mr. Abercrombie, in his excellent work on *Diseases of the Brain*, "seen children lie a day or two in a kind of stupor, and recover under the use of wine and nourishment. It is often scarcely to be distinguished from the coma which accompanies diseases of the brain."

In the cases above related, the pulse was quick, but feeble; the skin was cold, and the constitution previous to the attack of illness, was greatly debilitated by want of proper nourishment. These circumstances must guide the practitioner in his treatment. When he finds his patient labouring under symptoms of cerebral disease, combined with a feeble pulse, cold skin, and a con-

stitution naturally delicate, he may be sure that the symptoms indicative of an inflammatory affection of the brain, arise from a deficiency of nervous energy, and require for their removal every thing calculated to support and strengthen the constitution. From an inattention to these circumstances, many fatal errors have been committed.

## PROFESSIONAL REMINISCENCES.

### No. II.

MIDWIFERY CASES.—ULCERATED LEGS.—TRUE BENEVOLENCE.—DROPSY.—HERNIA.—CANCER.

I TAKE the advantage of a leisure hour to resume my pen, which is so much the easier task from my having pledged myself to no consecutive tissue of narrative or course of argument. I shall, therefore, without referring to my former paper, consult my memory, and proceed according to its dictates in the same desultory style.

That paper closes with cases of midwifery. To these I shall only at present add one or two more. I was the medical attendant during the birth of a first child, and first placenta out of three in a case of triplets. Each child had its separate placenta. In every case of *twins* that I have seen, both navel strings were inserted into one placenta of a somewhat larger than the average size. The spontaneous detachment of the first placenta after the birth of the first child, and this without being followed by the slightest hæmorrhage on its removal, was not the least singular circumstance attending this case. I was at that time an assistant. The gentleman with whom I lived was one of the most skilful accoucheurs in that part of the country. It was during his temporary absence that I supplied his place. As the case, both previously to delivery and afterwards, was but partially and incidentally under my care, I only have it in my power to mention that the patient did well, and that the children lived some weeks. Both children and after-births were very small.

I have one other little case to mention, which occurred more entirely under my own eye. A patient of mine, after a labour of some duration, accompanied with considerable hæmorrhage, gave birth to an apparently still-born child. The snuff box of a neighbour being at hand, it struck me that (without consulting Denman or Meriman) it would be no unwise thing to take a small pinch out of it, and administer to the

child. As it will not do at such junctures to be very *recherche* in one's choice of remedies, I placed a little on the child's lip, and blew it up its nostrils. I found this summary process answer the end as well, or perhaps better, than any more elaborate stimulant. The child very speedily sneezed, and showed other unequivocal symptoms of vitality, and though for some time very weakly, and destined to go through many struggles for its life, it is living at this time, a nice healthy child of near three years old.

I have given these two cases without note or comment; but I will make now a few remarks upon them. When any opinion we form in science appears to ourselves a doubtful one, it is best to set it down as such, and so leave it to abide the test of experience and observation.

In the last case of twins I attended, (both of the children being now, as their first appearance promised that they would be, alive and healthy,) the after-birth was larger than the three separate after-births in the triplet case put together. Is it, or is it not, the case *ceteris paribus*, and on the average, that fine healthy children have large after-births? Again, it is popularly believed that the occurrence of hæmorrhage in any great degree, particularly during the latter period of gestation, "spoils" the child's "longevity." It does not seem unreasonable to conclude that the *vis vitæ* of a child must be weakened and enfeebled from this cause, though by no means irrecoverably. When hæmorrhage during labour is very great, and has lasted long unchecked, we naturally expect to see a still-born child, and it is seldom that we have the pleasure of being agreeably disappointed. I do not promise to relinquish finally the subject of midwifery, but I shall for the present shift the scene, and commence a fresh train of reminiscences; some of them, perhaps, less strictly professional than the foregoing, but all of them owing their origin to my opportunities as a medical man, and the places which I have filled, and situations in which I have found myself in that capacity.

The first professional nuisance I learned to deprecate occurred to me, in 1817-18, when pupil to the late Jacob Jones, Esq., of Finsbury Square, who was surgeon to a public dispensary, I had to dress certain ulcers in the legs, (of annual, or sometimes perennial nature,) the property of poor people, who, ill fed and ill clad, were in the habit of drinking as much gin as they could get by way of counter-irritant to the general ailment of poverty and destitution. The consequence of this was a cachectic habit of body very unfavourable to the consummation of any curative process. Healthy pus would be secreted—healthy granulations

would form; and every-thing would go on swimmingly for a time, when on a sudden, some morning on removing the bandage and dressing, behold, a black livid-looking patch—the walls of the ulcer giving way and enlarging, and all our work to do over again! In vain we tried ung. picis, ung. hyd. nitrat., sprinkling with pulv. rhei., and a succession of stimulants and refrigerants, and what not, aided by the most careful bandaging; our labours were frequently like those of Sisyphus. Even when at length they were dismissed cured, experience taught us to be sparing of our orations, for there was no telling how soon, like Monsieur Tonson, they would come again. I dare say several fresh generations of ulcerated legs have in due course flourished since my time, to the edification of my successors in office. I may speak on this subject *con amore*, and the more feelingly, as the duty of dresser devolved mostly on myself. Such sores are much more manageable in the country. Diseases in London and in the country differ, and require different treatment. This holds good among the poor especially. There is much sense and knowledge of human nature (I mention this *en passant*) in a piece of advice to dram-drinkers which I met with some time since in a popular pamphlet. Persons who wish to break off a habit which, to say the least of it, is injurious to the constitution, are recommended to substitute a pinch of snuff for a glass of gin every time they want one, as being the more harmless stimulant of the two. There is no doubt that in this way the task of reformation would prove easier. The facilities afforded us by nature for breaking off evil habits and mal-associations, bodily and mental, are ample and numerous. The ability to make use of these constitutes a species of versatility of mind, which it is very desirable to cultivate. But I perceive that my paper is taking a *transcendental* turn.

To descend from these cloudy regions of semi-metaphysics, I remember it was about this time that Mr. Jones assisted with food, money, and, what, considering his immense practice at that time, was a greater boon than either, his professional advice and attendance, a man who had lapsed from a state of affluence into poverty, and who himself, in the advanced stage of decline, was living in an upstairs room, which contained one bed for the joint accommodation of himself, a wife, and four children. It was my part to visit them occasionally, both for and with Mr. Jones. He had been an officer in a dragoon regiment, and had given 900*l.* for his commission. This he, through imprudence or misfortune, was at length obliged to sell, and having no knowledge of any means of earning

money, had gradually sunk lower and lower in the scale of adversity. But let me not depict his condition in too dark colours. As instructive a moral lesson might be read to us, on the vanity of human apprehensions as on the vanity of human wishes. His sufferings were probably more apparent than real; in a great measure insensible to the presence of surrounding calamities, he was for the most part employed in thinking of another world, at first with anxiety, and afterwards with hope. Thus circumstanced with regard to worldly matters, let the world guess who visited this deserted and unfortunate gentleman in sickness and affliction? His brother officers—his gay companions of but a few years previous? No! By them he was probably forgotten. They either knew not of his adverse circumstances, or took no care for them. Who then befriended him in affliction? A few faithful men among the Wesleyan Methodists;—the unpaid, voluntary emissaries of the Benevolent Society visited him, relieved his temporal necessities, partly from the funds of the society, partly from their own private purses. Their kindness towards him was manifested with delicacy, and without ostentation; and through their charitable attentions and religious counsels, he enjoyed those comforts which sickness needs, and died "fearing God," and in a state of calm and peaceful preparation for a better world which monarchs might envy. In fact, I know no society on the face of the earth by which a greater aggregate of un-mixed good is effected. The only claim the objects of this charity have occasion to make, is founded on the humble merit of their being human creatures in distress, and such as bear this character, without seeking aid, are industriously sought out and relieved as far as the funds of the society will admit, often aided, as in this instance, by private and extempore benefactions.

Among the many dispensary patients whom I saw at their abodes in Golden Lane, Grub Street, London Wall, and other streets or their courts and alleys, was a woman who had ovarian dropsy, on whom I saw Mr. Jones perform the operation of tapping, about once every seven weeks, for the space of two years. It was not till some years after the first operation that she at length died. The recovery of a gentleman from dropsy of the abdomen, after having been tapped three times by Mr. Jones, also occurs to my memory. I have somewhere by me the minutes of his case, but cannot now find them. I remember about the same time, a case of narrow escape from the operation for incarcerated femoral hernia, in which, after the scalpels had been placed in order on the table by the late Mr. Taunton of Hatton Garden, who was to have ope-

rated, Mr. Camplin (Mr. Jones's partner, and now his successor) succeeded on a last attempt, in reducing it effectually. I need not say that the taxis, tobacco enemas, and every possible remedy, had been resorted to, before the operation was contemplated. But it is worth remembering that at the very last point of time left for such an experiment, five minutes' continual pressure should have been successful in reducing it, and saving a patient from a painful and hazardous operation. At the same time, I am afraid that I cannot say I rejoiced at this prorogation *sine die* of the said operation so much as I should. I believe I was guilty of entertaining some slight sensations of involuntary disappointment.

I would fain repeat some anecdotes which struck me much in Taunton's lectures, but I begin to think I have written enough for one time. The motto of a reminiscence ought to be

*Glasses mortels—n'appuyez pas.*

Accordingly, to avoid fatiguing my reader or myself, I shall now close No. II., with a recollection of more recent date.

The first case of chimney-sweeper's cancer that has occurred to me in my private practice, has proved a very satisfactory one in its results. About this time last year, a man in the neighbourhood of Wycombe who followed this occupation, showed me a small hard tumour in the axilla which had for some time been painful. The pain extended across the pectoral muscle in the course of the absorbent vessels, and was so great, that he was very willing to submit to any operation. As there appeared no doubt of the nature of the tumour—as there was a chance of its progressing and extending, and under any circumstances of its becoming large, and increasingly perilous to remove, and as (moreover) his father had died of a similar complaint,—I advised him to let me remove it. This I accomplished with little difficulty, and complete success. The wound went on favourably, and he has had no pain in the part, nor has any tumour formed there or elsewhere since. The tumour (which I have kept by me preserved in spirits), when cut open, exhibited very distinctly that incipient cancerous structure which is called scirrhus. As the wound was small, to make assurance doubly sure, I touched the bottom of the wound with lunar caustic, in order to destroy any fibres belonging to the removed tumour that might remain.

Once more I subscribe myself, Sir,

Yours obediently,

S. GOWER,

High Wycombe, Bucks.

Sept. 17th, 1830.

EFFICACY OF THE CHENOPODIUM OLIDUM  
IN CHLOROSIS.*To the Editor of THE LANCET.*

SIR,—In a disorder attended with such serious consequences to the female sex as chlorosis, which often lays the foundation of diseases terminating in death, I consider it the imperative duty of every medical practitioner to make known to the profession at large any remedy which he may have found useful in curing so important a malady. In recommending the extract, chenopodium olidum (goosefoot or sowbane) to the attention of the medical world as a remedy for chlorosis, I do not attach to myself the credit of discovering it, as I see the chenopodium vulvarium mentioned as an emmenagogue in Doctor Fox's Medical Dictionary of 1803. I have prescribed this medicine in several cases with uniform success, in doses of ten grains three times a day. During the administration of the remedy, attention must be paid to the state of the alimentary canal. I have found this treatment produce the catamenia in a very short time. It is likewise of great importance that I should state I have not found this remedy serviceable in amenorrhœa arising from plethora. In dysmenorrhœa I have had no opportunity of trying the chenopodium olidum, but I take the liberty of suggesting to my medical brethren the propriety of doing so. Perhaps uniting it with some of the usual remedies, as camphor and the extractum hyosciami, might render it efficacious in that disease.

I remain, Sir,  
Your obedient servant,

W. TAPLEY, M.R. C.S.

Brompton near Chatham, Sept. 22, 1830.

P.S.—The extract, chenop. olid. is prepared, I think, by Mr. Brand, chemist, Strand.

## A CASE ILLUSTRATIVE OF THE GOOD EFFECTS OF WHAT DR. MACARTNEY DENOMINATES "WATER DRESSINGS."

*By JOHN V. JACKSON, Surgeon.*

CAPTAIN M. LODGE, commander of an American trader, whilst with his ship in Dublin, received in his thigh the contents of a pistol accidentally discharged at him as he was ascending from the cabin to go on deck; a slug, with which it was in part loaded, entered his thigh at about its middle and posterior part; the pistol being discharged from below, the slug took a course obliquely upwards and inwards, and presented itself immediately beneath the fascia, about two inches or two inches and a half

from the place at which it entered; previous to my arrival, an incision about an inch in length had been made by a gentleman present, over the surface of the slug, and an ineffectual attempt had been made to extract it, owing probably to the fascia being insufficiently divided; having enlarged the incision already made, it was carried down until the slug was completely denuded, which was then easily extracted by a pair of common forceps. No vessel requiring a ligature being divided, the wound being well cleansed, a *pledget of lint, dipped in cold water*, was put over them, *over which was placed a piece of oil silk* (as recommended by Dr. Macartney in his valuable lectures); this, with the exception of occasional aperients, constituted the whole of the treatment adopted; and so effectual was it, that at the expiration of ten days he was enabled to resume his duty; and during the period above named, he never endured ten minutes' pain. In clean incised wounds, as well as those received during dissections, this method of treatment has been found most beneficial, the parts to which it is applied immediately losing their morbid sensibility.

From the oil silk preventing evaporation, the parts are kept as it were in a continual vapour-bath; and probably to this cause, and to all atmospherical impressions being taken off, the good results attending this method of treatment may be ascribed.

Yavin, Yorkshire, April 23.

## ELECTION OF CORONER

FOR THE  
COUNTY OF MIDDLESEX.

## SKETCH OF THE PROCEEDINGS.

SEVEN candidates offered themselves for the office of coroner for Middlesex, immediately on the death of Mr. Unwin; the most prominent of these were, Mr. Baker, Mr. Burford, and Mr. Gude, sen. After the lapse of some days Mr. Wakley added himself to the number, and gave to the contest, agreeably to the language of his opponents, a character which it had never before possessed in this county. Four of the seven candidates retired soon after Mr. Wakley announced himself. The remainder continued the very active canvass which they had commenced, and obtained, as they respectively stated, "a sufficient number of promises to give them confident hopes of success," before Mr. Wakley was enabled to make his claims known to the freeholders. The starting of Mr. Gude, sen., it shortly appeared, was an artifice, for

after he had remained just long enough in the field to secure a certain number of votes in his interest, he resigned in favour of his son, leaving numbers of his supporters under the impression that they were supporting the pretensions of the father. As the day of election approached, and the prospect of a firm and decided contention on the part of the medical candidate became more certain, symptoms of withdrawal were evinced by two of the attorney candidates. Mr. Burford was the first to resign, and a claim upon the votes promised to that gentleman, was immediately made by Mr. Baker. A short time after this Mr. Gude, jun., also resigned, but not until Mr. Gude, sen., had made a distinct offer to Mr. Wakley, in the presence of Mr. Wallis, of the votes and personal influence of Messrs. Gude, on payment of a "good round sum." The overture of course was at once rejected, and three days afterwards a letter of resignation in favour of Mr. Baker appeared from Mr. Gude, jun. Thus strengthened by the unprincipled combination of the attorney candidates, the contest was maintained nominally by Mr. Baker,—Mr. Wakley standing at last, as he did at first, entirely alone.

An account of the commencement of the polling on Thursday, the 9th of September, has already appeared in the pages of this Journal, and the following are the numbers which appeared at the close of each day :—

Sept. 9, Mr. Baker .....	605
Mr. Wakley .....	333
Sept. 10, Mr. Baker .....	538
Mr. Wakley.....	399
Sept. 11, Mr. Baker .....	391
Mr. Wakley.....	290
Sept. 13, Mr. Wakley.....	563
Mr. Baker .....	443
Sept. 14, Mr. Wakley .....	360
Mr. Baker .....	234
Sept. 15, Mr. Baker .....	301
Mr. Wakley .....	288
Sept. 16, Mr. Wakley.....	296
Mr. Baker .....	251
Sept. 17, Mr. Baker .....	215
Mr. Wakley.....	203
Sept. 18, Mr. Baker .....	271
Mr. Wakley.....	258
Sept. 20, Mr. Wakley .....	544
Mr. Baker .....	421

Amount of the gross poll ;  
For Mr. Baker.....3670  
For Mr. Wakley ....., 3534

Majority for Mr. Baker ..... 136

The cause of the great disparity of numbers polled by the two candidates on the first three days, was obvious enough to the spectators ; for while no active arrangements were made by Mr. Wakley's committee to bring up voters from the country before Monday the 13th, the most strenuous efforts were made each day by Mr. Baker's friends in every quarter. Thus 1020 almost unsolicited votes were polled by Mr. Wakley, principally from amongst his friends immediately in the vicinity of London, at a time that the arena in front of his opponent's committee-room was hourly crowded with coaches and other vehicles, forced into requisition at the very onset of the contest.

On Tuesday the 14th, after the close of the poll, Mr. Gude, sen., who during the whole of the contest took a most active part on the hustings (conjointly with Mr. Burford), as a partisan of Mr. Baker, came forward and declared, appending to his declaration the solemn affirmation of his oath, that he had never made any offer whatever of his son's votes to Mr. Wakley for a sum of money. On the conclusion of this denial, Mr. Wallis presented himself and fully confirmed the statement of Mr. Wakley, that the offer was made in his (Mr. Wallis's) presence, and at Mr. Gude's own house.

During the whole progress of the election, the enthusiasm in favour of a medical coroner was of the most marked and decided kind ; and an impression has been created in the public mind which can never be obliterated. The crowd assembled before the Sessions House was on no occasion during the addresses of the candidates, less than 10,000 in number ; it repeatedly extended to 20,000, was 30,000 on the fourth day, up to which time not an individual connected with the politics of the country had appeared on the hustings, and on the last day, not fewer than 60,000 persons must have been collected on Clerkenwell Green. It is most gratifying to be enabled to add, that notwithstanding the extent of this unequalled assemblage—unequalled in point of numbers, fervour of feeling, and clear apprehension of the merits of the question under discussion, not a single accident or breach of the peace worthy of being named, is on record. The urgent appeals made by Mr. Wakley, that good temper and order might be preserved, were obeyed to the letter. The strongest plaudits, as may be supposed, were bestowed on

those who gave their suffrages for Mr. Wakley, and loud expressions of regret fell to the lot of those who voted for Mr. Baker, but with this, all indication of warmth of feeling ceased, and hundreds of the freeholders who assisted in placing Mr. Baker in the office of Coroner, left the scene after once having visited it, with unqualified expressions of sorrow that they had not previously considered the importance of the question on which they had been deciding.

It remains to be added that the poll was closed at 4 o'clock on the 10th day, while the sheriffs had the power, if they had chosen to exercise it, of keeping it open until 5, and that a body of freeholders was at that time upon, or was close to, the hustings, waiting to record their votes for Mr. Wakley, in sufficient numbers to have triumphantly carried the election in his favour, had the hour been allowed to them for polling. On hearing the announcement of Mr. Baker's election, Mr. Wakley handed to the sheriffs a paper signed by several freeholders demanding a scrutiny, which paper was afterwards withdrawn, for reasons which Mr. Wakley has explained in the following extract from an address to the freeholders, conveying to them his thanks for the hearty support he received in the struggle. As this extract contains matter of importance in the history of the election, and explains in Mr. Wakley's own words the causes which operated to defeat his object, it will find an appropriate and permanent place in this brief sketch of the proceedings.

"The first disadvantage under which I laboured during the contest, unquestionably arose from the lateness of my appearance in the field. The canvass of the other Candidates commenced at least a week before my name was announced, and the inquest on Miss Cashin occupied my attention for several days after, so that it was not until a very short time previous to the Election that I was enabled to commence my arrangements for the contest. Meanwhile, my numerous opponents had so far profited by this unavoidable delay, that three of them had gained a sufficient number of promises to give them, to use their own words, 'confident hopes of success.'

"But the great public question for which I have so long been contending was at last submitted to you. You were reminded that the duties of a Coroner required a MEDICAL, and not a legal education. Your decision was immediately given in my favour, and so distinctly was the voice of the freeholders heard, that, as the day of election approached, my competitors, in spite of all their advantages, one by one, with a single exception, relinquished the contest, turning over their several "interests," however, from candidate to candidate, by harter and trans-

fer, until at last the influence of all of them was united in one. To this unprincipled combination I could only oppose the good sense, the public spirit, and the independence of the freeholders who had not already promised their votes.

"It was soon confessed by my opponent, that against the declared feeling of the county he stood no chance, unless he resorted to means which entailed upon him a "ruinous expense," and to these means he was ultimately driven, though ineffectually. For, at length, notwithstanding all the advantages of an early canvass—notwithstanding all the coercive influence of landowners, and employers—notwithstanding the coalition of five or six candidates in favour of one,—and notwithstanding the "ruinous expense" incurred by my antagonist, the cause of principle and independence triumphed, and the real "victory" was ultimately ours. How at length this victory was torn from us, and the means by which your decision was forcibly reversed, can hardly be described with patience, or read without indignation.

"From the extraordinary and unequivocal character of many of the occurrences which were developed during the progress of the polling, I felt it to be an imperative duty to demand a scrutiny; but this demand, to my utter astonishment, was not conceded. I was offered, it is true, a scrutiny, to be commenced and completed on the instant, consisting merely of a comparison of the poll-books by the books of the check-clerks, and involving no investigation of the real character of the votes themselves. But such a scrutiny as this I naturally declined. A real *bona-fide* scrutiny of the votes, I was told, the Sheriffs were not by law either compelled or empowered to grant. I was aware of this defect in the law, but my appeal to the Sheriffs was not made on the ground of legal enactment, but on the broad principles of justice and impartiality.

"Thus have we been defeated; but whether I shall submit to a decision so unjust, or appeal to a higher authority, remains for consideration. Remember, however, that you may again, before long, be called upon to decide the same question in another case, and I pledge myself to stand forward as a candidate at the very first vacancy. \*\*\*"

So fervent was the feeling in favour of the medical candidate, that at the close of the election the horses were taken from Mr. Wakley's carriage, and that gentleman was drawn by the populace to his house in Bedford Square, attended by a concourse of at least ten thousand individuals.

## DINNER TO MR. WAKLEY.

(Revised from the Report in the Morning Chronicle of Sept. 29th.)

ON Tuesday the 28th, a public dinner was given to Mr. WAKLEY, at the Crown and Anchor Tavern, "to celebrate his able and manly advocacy of the cause of justice during the late contested election for the office of Coroner." THOMAS KING, Esq., D.M.P., in the Chair. About a hundred and thirty gentlemen sat down to dinner, the whole arrangements of which were highly creditable to the stewards and the proprietor of the tavern. A small band, and several excellent professional singers, were present.

The cloth having been removed, and *Non nobis Domine* chanted,

The CHAIRMAN rose and said:—In attachment to public virtue I think this assembly will yield to none; still less will it yield in attachment to our patriot Sovereign. Gentlemen, I give you "The King." [*Drunk with the usual honours.*]

The CHAIRMAN then said;—The best omens of the prosperity of a reign are to be derived from the events which mark its commencement. The Queen cannot be indifferent to any thing so intimately affecting the administration of justice as the conduct which we are met to celebrate. I am sure you will very cordially receive the toast it is my duty to propose, "The Queen and the Royal Family." [*Drunk with much applause.*]

Mr. HUNT then gave—"The people,—the only source of legitimate power."— [*Drunk with cheers.*]

The CHAIRMAN again rose, and said;—I am too deeply impressed with the importance of the next toast which I have to give, not to wish that it should be presented to your notice more worthily than it is in my power to give it, labouring as I now am under severe indisposition. It consoles me, however, to recollect, that the toast is one which requires no recommendation to you, and little comment from me; yet I cannot, on so remarkable an occasion, refrain from saying a few words. It is often my lot to observe the conduct of public men, and the difficulty there is in obtaining the support of gentlemen of talent where the public interests are concerned. The comforts of domestic society are often too numerous, and the cost often too great, to permit them to enter the arena in which their abilities would be of essential public advantage; and many good men thus withhold from their fellow-creatures the services they might render them. If then, Gentlemen, we find one man in the circle around us, who is

ready to sacrifice every thing he possesses to the public good, with what satisfaction should we hail his appearance amongst us. We have such a man amongst us now, an active, able, virtuous citizen, and I beg leave, with your permission, to propose his health to you as the future Coroner for Middlesex. [*Great applause.*] You are all acquainted with his entry upon public life; the obstacles he has had to encounter, the difficulties with which he has been surrounded. Alone and unsupported, Mr. Wakley has withstood the efforts of the most powerful public body in the state. You have seen how nearly he has been overthrown—you must have feared that he would be entirely overpowered; but, Gentlemen, by pursuing one honest, straight-forward, manly course, he has surmounted every one of the surrounding dangers, and risen superior to all his enemies. His first care on entering the profession was to see that the sick poor were properly managed in our hospitals; and no man in England will be so presumptuous as to deny, that ever since the establishment of THE LANCET, our public medical institutions have gradually been improving. Their officers have become more regular and assiduous in their attendance, and have exerted themselves more strenuously to save the lives of those who have been committed to their care. But THE LANCET has had another and equally important duty to perform,—that of securing the justice to medical pupils, to which all Englishmen are entitled, and that courtesy to them which is due to all gentlemen. Before the publication of THE LANCET, the medical pupil was at the mercy of the hospital surgeons—men who obtained their offices by intrigue, with whom all depends upon influence and favour, and nothing upon intelligence, knowledge, or capability. Prior to the period of which I am speaking, the young medical pupil was driven to the degrading necessity of submitting to all that was imposed upon him; but THE LANCET appeared—threw open its pages for the publication of every act of injustice or oppression that was committed, and afforded that best shield against the tyranny of the powerful—publicity. It has done still more than this for the profession, and I am proud to say it has had many assistants. It is a remarkable fact, that with the exception of Mr. Hume, and Sir James Mackintosh, the House of Commons does not contain a single member who has been educated to the profession of medicine. Yet the good that would be effected by their presence there would be immense. This gross fault in our legislature Mr. Wakley has often endeavoured to correct; he has repeatedly tried to stimulate men to come forward and support medical men as members of parliament. As he proceeded in his pro-

professional course he turned his attention to the great public offices of the country, and Mr. Wakley, and Dr. Gordon Smith, were the first to direct public attention in an effectual manner to the glaring abuses which arise from the appointment of non-medical men to the office of coroner. He was the first to trace out the lamentable errors which thus often occur in our courts of law. It is unnecessary for me to enlarge on this point; but it does appear to me that the good which would arise from reform in this respect, would be incalculable. Even one case will be enough to show the truth of this opinion. Let us take that which occurred only a few days since at Guy's Hospital. I saw by the papers, the other day, that a man, whilst running in the street with a pipe in his mouth, slipped and fell, and suffered a severe wound in the tongue from the pipe. He was soon taken to the hospital, where he died in forty-eight hours. It appears that a piece of the pipe penetrated his tongue, and there broke off; a portion was extracted, and I read that a medical gentleman, who was examined on the inquest, declared that it was impossible to discover whether any part of the pipe was still remaining embedded in the tongue. The man remained in the hospital, and appeared to be going on without any bad symptom, when of a sudden he died, and it was found that a long piece of pipe was actually remaining in his tongue. Now one of the jury was anxious to put some question to the witness, with a view to ascertain whether ignorance, or thoughtlessness, or neglect, had occasioned the want of discovery that this piece of pipe was still in the tongue, and the death of the man occasioned; but he evidently did not know what question to put that would elicit the truth, and the coroner knew as little. Now what a state of things is this. A competent coroner would have said, "Did you collect the various pieces of the broken pipe, and see whether the entire length was in your possession, without which you might have suspected that you had left a portion behind in the tongue?" This, of course, the medical man had not done, and do you not think that here was some gross dereliction of duty to the patient? When a foreign body produces a wound, the first question we should ask is, of what length was the instrument; what was its nature; and whether it was found externally. Now in the case I have mentioned, under a fit coroner a jury would undoubtedly have seen it right to append to their verdict a very proper censure on the attendant. But the officers of our hospitals are not elected by honest public competition, and are almost indifferent to the melancholy results which

their neglect occasions. The question of a medical coroner then is one of vital importance, and many others which have been regarded as paramount to it, are trifling on comparison with it. It was astonishing to me during the late contest, that any men could be found to support such an iniquitous custom as has hitherto existed. That they were unable to defend it, or did not dare, or did not deign, to do so, was evident enough. We gave them every opportunity of denying our statements and confuting our arguments, but not once did they come publicly forward to discuss the question. In the selection of a medical candidate, those who sought for one, acted most fairly. They wished to see a man in the situation who was profoundly versed in science, able in mind, conscientious in heart. They looked around. It was difficult to select such a man; but at last they fixed on one who had never scrupled to sacrifice his all to the public good. Prior to that time I had, gentlemen, but little acquaintance with Mr. Wakley, but now that I know him, I can speak of him without hesitation. I have lived in terms of intimacy with many of the greatest men of many countries, and I say it distinctly, that in the possession of great public qualities, Mr. Wakley is superior to any man I have ever known. For unbending integrity, for unwearied activity, and for social virtues—I say it from the bottom of a heart, which I hope is an honest one—I believe he has not many superiors living. I beg leave to propose his health. [*Immense cheering.*]

Mr. WAKLEY rose to return thanks, and said, Mr. Chairman, and Gentlemen,—Friends, I believe I may say; I should be something more or less than man, if I were not deeply impressed with what I have heard this night. The eulogy of your excellent chairman is far beyond any deserts of mine, and I am bound to say, that if my claims on your good opinion were very far greater than I feel them to be, I should not even then deserve the approbation he has bestowed on me. I can only say, that from the moment I first entered upon public life, I have endeavoured to discharge my duty, and that I have never suffered private interests of any kind to induce me once to swerve from that which I conceived to be demanded of me as a public journalist. THE LANCET has been mentioned to you. I saw with deep pain, that in conducting that Journal, my private interests were opposed to my public duty. I felt, that if I wanted to conduct the Journal for the benefit of the profession, I must make my own interests yield. Temptations were thrown in my way, but I had the power to resist them, and I pursued an upright purpose, with a firm assurance, that the result would at last

revert with honour on my own head. The day which I then foresaw has arrived, and I now receive from you the only reward that I ever wish to obtain on earth. I have often been assailed, I am still assailed, on the right hand and on the left; I am abused from behind, but few there are who ever venture to meet me in front. My dirty foes are ever at their work in secret. "Wakley," said they, "is a bad fellow;" and when they were unable to reply to my arguments, then it was found, for the first time, that I was all that was infamous in private character. When I commenced *THE LANCET*, it was worthy of note how well the work was received: there was then nothing whatever objectionable in it. The hospital surgeons said, "Oh it is a very good publication that *LANCET*; it will make us known; people in distant parts will hear of us; they will know who are the officers of the hospitals." Yes, Gentlemen, "and without hearing how we are elected," thought they. (*Loud laughter.*) *THE LANCET* went on, and we were "Hail, fellows! well met." Six months passed over, and the infant was still much approved; but no sooner did it attempt to toddle alone and move its hands and feet with an appearance of energy, than "The child was a very froward one—a most unnatural child. It whined; it was not quite so agreeable as it used to be; the public could hear its cries, and that was by no means pleasant." And why? Because there was no applause mixed with its cries. So long as it was silent, or afforded praise only, so long it was a most respectable work; but directly it began to expose a few of the misdoings in our hospitals, then *THE LANCET* was the worst publication under the sun, and Mr. Wakley the vilest fellow alive. There was no crime, no species of treachery, of which he had not been guilty, and they said, "He has no supporters." At first, we were on the most friendly terms, but this ceased when I thought it my duty to raise my voice in favour of truth and the public rights. Then it was, that abuse felt thickly around; but, Gentlemen, had I really been as vile a being as they described me, I should have been eating their mess this day, instead of feasting with you. I had the resolution to pursue an honest course, and now the man does not live who is happier. I cannot be otherwise. We have been engaged in an arduous struggle for a just cause, and I take it that you have invited me here to day, to say to me that I have discharged my duty to the public. I have gone through this contest with, I believe, the fairest feelings. I said to Mr. Baker at the first,—I do not mean to act vexatiously. I will not spend five pounds after I have good reason to believe that my chance is hopeless; and I assure you, that if after the first

day, I do not see that I have a fair chance of success, I will at once retire; but hearing from my friends, in every quarter, that the election must be mine, I should have acted basely towards the county if I had not afforded the freeholders an opportunity of recording their votes even to the last hour. I gave them that opportunity; they came forward manfully, and a greater triumph for principle never was achieved. It was the triumph of independence; for look at the expenses which I have incurred in the election. They are by no means large. On the other hand, attend to the confession of "ruinous costs" made by our opponent. The attorney coroner has got nothing by his election but a responsible situation and a large debt. And how do you think that debt was incurred? Not indeed in proving the independence of the county. I am quite satisfied that Mr. Baker was no voluntary sacrifice on this occasion, but that he was thrust forward by persons who remained in the back-ground. May be he is not the last unfortunate gentleman of whom a victim will thus be made. I do not know how many will volunteer to come forward on the occasion of another vacancy, but, whatever their numbers, I am prepared to meet them on the old ground, and promise them as good a dissection, as Mr. Baker has just experienced. Before, however, a fresh candidate thinks it advisable to ascend the ladder to which I was of necessity driven, I shall advise him to apply to Mr. Baker, and learn from that gentleman the pleasures of such a contest, for really it is nothing more than the strict truth to say, that during the election Mr. Baker was an object of pity, and the same may be said of most of his friends. There was Mr. Samuel Whitbread—"Soft Sam," as they impertinently call him at Bedford, who came to the hustings to propose Mr. Gude, and finding Mr. Gude had resigned, accomplished his mission by proposing Mr. Baker; to him it did not matter which; it was all one to Mr. Whitbread. He proposed then an attorney coroner, and enlarged on the "necessity" of a lawyer filling the office, and I need not tell you what an object he made of himself. Yet we gave our opponents every opportunity of supporting their doctrines by arguments. As for Mr. Baker himself, on questions connected with medicine, he would not encounter me at all, and on points of law I believe it will be admitted by all who are present, that I beat him hollow. He showed pretty clearly that he had no claim to your suffrages on the score of competency, and on what then did he depend? Why, on the excellence of his private character! But I ask you, Gentlemen, does private character alone present sufficient grounds to warrant the intrusion of any man into a vitally im-

portant public office? Is it an efficient apology for thrusting an attorney into the highest medical chair in the kingdom? Regard the office for a moment. There does not exist a more important one. It was specially appointed for the protection of the people, and demands something more than private character for the execution of its duties. Gentlemen, Mr. Baker the other day held his first inquest, and, if report be true, that inquest required such a degree of medical knowledge, that the verdict, however satisfactory to himself and to the jury, cannot by any means be deemed satisfactory to the well-informed portion of the community. The body of a woman having severe contusions upon the scalp was found hanging to the iron rail of a window, and this it seems was sufficient to enable the non-medical coroner and jury to determine, that the deceased had hung herself in a temporary fit of insanity. It did not appear, from the evidence of the surgeon, that the body had undergone any *post-mortem* examination. The head was not opened, the state of the lungs was not ascertained, at least according to report. But a rope having been found about her neck, and the body having been discovered hanging, these facts were considered to be conclusive that the woman had hung herself. It never suggested itself to the mind of the non-medical coroner, or to the jury, that the woman might have died or been killed first, and hung afterwards; and let it be fully understood that I throw out no insinuation that there was the least ground for believing that other persons had laid violent hands upon this woman; but as the coroner and jury had met for the sole purpose of investigating the causes of death, it was their bounden and imperative duty to seek for the best evidence, and surely that alone could be found in the internal organs of the body. The brain and lungs unquestionably should have undergone an attentive examination. Not many years since a body was found hanging in this way at a village in Ireland, the name of which I do not now recollect, and it was afterwards proved that the deceased had been murdered by her husband, who, in order to screen his own guilt, had suspended the body by a rope after he had strangled her, and had nearly by this artifice escaped punishment; but he was subsequently executed; not, however, until he had fully confessed the crime of which he had been found guilty. The consideration of this point brings to my recollection an article which appeared in *The Morning Herald* of this day on the subject of non-medical coroners, in which the writer—it cannot be the Editor of the paper,—endeavours to justify their appointment, and perpetuate the present injurious system. The first thing he is ingenious enough to find out

is this—and it will be worth while for me to give you a specimen of the reasoning which is employed on these occasions—that it was not proper to say anything on the subject during the election, but that it is proper to do so now. Pray, was the writer a prophet; that he foresaw the result of the contest, and, therefore, knowing what would happen, did not consider it necessary to put in the weight of his logic against medical coroners, until it could have no effect upon the election. Surely if there was a proper time at all, that time is gone by, and our opinions are not very favourably secured; for what the writer has further to advance. Let us observe what he says: “But if it be necessary, for the right administration of justice on coroners’ inquests, that the officer who has to sum up the evidence and state the law to the jury, should be a medical man, how much more necessary is it that the jury should be composed of the disciples of Galen!” Mark the tendency of this argument. It in reality goes to allege, that because a jury is ignorant of the nature of the evidence before them, it is of paramount importance that the head of the court should be equally ignorant! It is most unfavourable for the parties implicated; that there should be even one person on the inquest who is capable of eliciting the truth. That is evidently his argument, and he continues it by alleging, that if it be necessary for the Coroner to be a medical man, it is of course required that the twelve judges and all the recorders should be physicians or surgeons. The writer has forgotten that the Coroner has the power, the unconstitutional power, to exclude the public from his Court, and also that he has not the power to call persons before him, who are merely enabled to state opinions connected with the matter under inquiry; that his inquests are often held within the walls of close corporations, and that his witnesses are frequently the chief culprits; his Court being inquisitorial merely, and his power limited to the examination of witnesses of a particular class, a very profound knowledge of the duties connected with the coroner’s office, and of the demands of public justice, is not necessary to convince us that the presence of one person at the inquest, who is capable of eliciting the truth from the witnesses, is a desideratum of no trifling importance. And pray, how, is it that attorney coroners ever elicit the truth? Is there any medical man in the kingdom who cares a farthing for the cross-examination of such a personage? He may answer the questions put to him in the most absurd manner without detection. He might say that a sesamoid bone existed in the middle of the brain, or on the first joint of the great toe, and the coroner would not dissent. Suppose a patient in one of our hospitals be

killed by bad treatment or neglect: an inquest is held there; the hospital is a snug corporation; the treasurer is at the head of it; every thing goes on quietly; the coroner may take a glass of wine with the treasurer, and go into the inquest room; and who, pray, gives evidence there as to the cause of death? Who gave evidence in the case of the broken pipe mentioned by the chairman, which case, had it been so treated in private practice, would have ruined the attending surgeon? Why, a dresser in the hospital; not the surgeon, but a young gentleman. Now this is a case of everyday occurrence, and the witness might have said, that a brick-bat, or walking-stick, was in the tongue of the man, without fear of the Coroner. Gentlemen, I have seen the Coroner asleep over the body; and a case has lately been made public, in which three inquests were held on the body of one living woman. But our opponents say this is no fault of the coroner; it is his business to decide according to the evidence before him. Very true; it is his duty to do so, but surely he ought first of all to understand that evidence. Take the case of the man in Guy's Hospital. The Coroner hears that the man had a pipe in his mouth, that the pipe was broken, and penetrated the man's tongue, that hæmorrhage ensued, and the man died after some days; and thus he decided that it was "accidental death," without further consideration. It is true the wound was originally occasioned by the fragment of the pipe; but what if there were neglect on the part of the medical officers of the hospital? Gentlemen, a medical Coroner would not readily have recorded such a verdict as was returned in that case. The evidence of the dresser would not have satisfied a medical Coroner. He would have known that a dresser is an unfortunate youth, who generally comes up from the country with more money in his pocket than wit in his head, and who, yielding to the temptations of a corrupt body of men, pays a certain sum to them to be permitted to walk round the wards of the hospital, with a box of lint in his hand—no more. By the rules of the hospital, were he qualified, he could not operate: he cannot act as a surgeon, and you will scarcely credit it, when I tell you that Guy's Hospital with its enormous revenue, has no resident surgeon to attend to cases of emergency. But, gentlemen, if there were none but medical coroners, that institution would have a resident surgeon in two months, and the coroners would not hold inquests in the hospitals unless the doors were thrown open to the public, and then he would take especial care that the surgeon appeared before him; he would make him explain the treatment he had employed; he would demand his case-book, which instead

of a blank and empty document without a remedy or a prescription in it, would soon become a faithful and valuable record of the cases. I am speaking in the presence of a great number of medical men who are well able to correct me if I do not state notorious facts, and to the cases I have mentioned, I could add dozens of others. (Mr. Wakley here detailed several which he stated he had selected, because they had all been before the public, and had never been disproved.) Let us for a moment turn from the town to the country, and see what effect medical coroners would have there. Observe how it would operate in the case of medical pupils; what an impetus it would give to medical education. When pupils are in London, the only thing which they regard with apprehension, is the insignificant examinations at the colleges; but let them be aware, that after their return to the country, they may always be liable to undergo a strict medical examination before competent medical judges; the desire to do this with credit and honour, will act as a stimulus to study and scientific inquiries, to the last hour of their lives. Look, also, to the effect it would have upon the care of the poor in your workhouses. Observe its operation in the lunatic asylums. Who is the non-medical coroner that can discover whether the sudden death of a miserable patient, is caused by an accidental fall, or a blow from a keeper? Do you ever hear of an inquest in any of those institutions? Gentlemen, it is your duty to call for a pledge from the men whom you may elect to fill the office of coroner, that he never will hold an inquest in a lunatic asylum, because the public are never permitted to be present. Should I ever have the honour to fill the office, were their walls of adamant, or their chains strong enough to bind Olympus, nothing should deter me from exposing their proceedings to public view. How is it that such a state of things has existed so long in this country? The people of England are called a "thinking people," but they have a strange way of showing their knowledge. Our public medical institutions for sick, are as secretly managed as the harems of the east. You send patients there readily enough, but the moment they have entered—having on their way thither passed the doors of perhaps fifty competent practitioners,—you cease to take any further interest in their welfare, and leave them to the mercy of any-body into whose hands they may fall, competent or incompetent. Now, gentlemen, it was in consequence of these evils that I offered myself for the office of Coroner,—not to reform abuses, but to correct them, to remove them. I made the attempt, but failed. The next time, I trust, I shall be successful; but,

whether so or not, never shall it be a charge against me, that I have resorted to dishonourable means to secure success,—that I have endeavoured to ruin my opponent's reputation,—that I have brought forward charges which I could not, or was afraid to, substantiate,—that I misrepresented his words, and put falsehoods into his mouth,—conduct which, I am sorry to observe, has been pursued in a most unprincipled manner by those who have opposed me in the late election. Mr. Baker has been shamefully guilty in this respect. He alleged, as you know, that I uttered words of an unwarrantable description, and that he could prove them in a court of law. Mr. Baker, although he must have repeated the words he has described as having fallen from me,—must have written them,—must have read them again and again,—could not repeat them without reference. He was mute as death when I charged him on the hustings with base and unpardonable misrepresentation; nor has he yet had the manliness to acknowledge his error. It is most disgraceful that he has not since come forward for this purpose. Equal reason had I also for complaining of the letter in which Mr. Baker used the names of the Sheriffs to induce unqualified persons to vote for him. For, seeing the readiness with which many who had no right to poll came forward to take the oath of qualification and vote for that gentleman, it was a most unfair proceeding. Numerous are the instances of this in the poll-books. Many persons, it is said, voted twice in my opponent's favour; the name of one man, in particular, occurs to me at this moment, it is that of Ginger, and we shall probably see him, as well as some others, to answer for his perjury in another court before long. Never will we resort to these modes for securing an election. In the last of my opponent's advertisements, he is bold enough to repel the charges of unfair means, but in the same sentence he deplores the immense debt and expenditure in which he has become involved; but how, pray, was this debt incurred, if not in the purposes of bribery and corruption? [Many gentlemen in the room here stated their ability to prove instances both of bribery and perjury.] Gentlemen, I ought now to apologise to you for the length of time I have occupied your attention; but my head contains such a mass of matter on this subject that I scarcely know where to select or when to conclude. Permit me, finally, to call upon you for your strenuous exertions upon a future occasion. I request you all to be firm, to put your shoulders with vigour to the wheel, (*shouts of, "We will,"*) and secure the victory which awaits you. For my part, you shall ever find me ready to resume my old position at the hustings. Gentlemen,

this is one of the proudest days of my life. I shall ever remember it with gratitude. I rejoice that you think I have merited the honour which you have this day conferred upon me, and by every future act of my life, I will endeavour to deserve and obtain your esteem.

[At the conclusion of this address, which we have been compelled to reduce to its present limits, Mr. Wakley sat down amid several rounds of the most enthusiastic applause, with assurances of support at the next election from every quarter of the room.—*Rep.*]

The next toast was, "The 3534 independent Freeholders who had recorded their votes in favour of the principle, that Coroners should possess medical as well as legal knowledge."

The CHAIRMAN in proposing that toast, pressed upon their consideration the circumstances under which those men came forward—not merely to vote for Mr. Wakley, but against a combination of five candidates whose interests were blended into one, against that most righteous cause of which their honoured guest was the representative. Notwithstanding their lateness in the field—notwithstanding the leaning of all men in place towards Mr. Baker—he believed that they would have succeeded had not unfair practices been resorted to; and nothing could more deeply impress him with the conviction than did the late contest, that elections could never be pure till vote by ballot was legally recognised. (*Drunk with loud applause.*)

Mr. WALLIS then proposed "The health of Mr. Hume, the Member for Middlesex." It was the health of a man known not only to them, but to the whole kingdom, for every quality which could honourably distinguish a member of parliament, or a private gentleman (*applause*). "The Health of Mr. Hume" (*three times three*).

Colonel JONES, as the public and private friend of Mr. Hume, rose to return thanks, not only for drinking the health of a man whose public conduct he approved, and whose private worth he estimated, but for the very cordial and handsome manner in which they had paid him that distinguished compliment. Every one who desired reform must have rejoiced at the letter written by Mr. Hume with respect to the fitness of Mr. Wakley for the Coronership; but there was no one at the same time who knew Mr. Hume who did not feel perfectly satisfied that that letter was written solely upon public grounds, and not from any private consideration whatever. He knew that the two gentlemen were not even acquainted with each other. When he (Colonel Jones) went to the hustings for the purpose of supporting Mr. Wakley, he was

immediately surrounded by several of his acquaintances, inquiring what brought him there; many of Mr. Baker's friends saying to him, "Have we not brought in your friend Mr. Hume; have we not walked him over the course like a gentleman; and will you now turn round and oppose our friend, Mr. Baker?" To that his reply was, that the supporters of Mr. Hume must have acted from feelings of public duty, and that that ought to be their sufficient reward. Those were the terms upon which the representation of the County was accepted. He would tell them the motive which led him to the hustings; he went to give his vote to Mr. Wakley on strictly public principles; but he also felt bound to go as an act of justice. He had taken up the idea, in common with others, that the calumnies propagated against Mr. Wakley were not without foundation. Further inquiry satisfied him that he was in error, and he came upon the hustings for the purpose of reading his recantation; and he then begged to repeat that recantation there. He went again on the last day of the election, anxious for an opportunity of declaring his conviction that Mr. Wakley was an injured man. No doubt the base calumnies operated greatly against Mr. Wakley; but he had made the most minute inquiries, and was thoroughly persuaded of their falsehood. He, as a gentleman, and as a man coming forward in public life, hoped to be allowed to declare his conviction, and upon his honour, that they were false and groundless. (*Loud applause.*) In the name of his friend, Mr. Hume, he begged to return them his most sincere thanks.

The next toast was, "The healths of the Rev. Mr. Evans and Mr. Rogers, the Proposer and Seconder of Mr. Wakley on the occasion of the late memorable election."

Mr. ROGERS briefly returned thanks, assuring them that he became the seconder of Mr. Wakley upon grounds strictly public,—the course he adopted was influenced solely by a conviction that no man could be fitter for the situation. His first acquaintance with Mr. Wakley arose from that indignation against oppression, whatever form it might take, for which that gentleman was so conspicuous. He was not one of those who thought that a mere lawyer or a mere medical man was fit for the office, but from Mr. Wakley's knowledge of life, public and private, his decided leaning to the side of the people, and the rights of every man in the community, he thought that no-where could there be found a man better fitted to become a Medico-legal Coroner than was Mr. Wakley.

Mr. T. EVANS having been called upon by the Chairman, proposed "The Healths of the Ladies of Middlesex, and Thanks to

them for their exertions in behalf of the good cause of which Mr. Wakley was the champion." He could not help, upon such an occasion, alluding to the deep interest which Mrs. Wakley took in that great and memorable election, and he further could not help declaring his conviction that no inconsiderable portion of Mr. Wakley's almost superhuman exertions were inspired by the home department. (*Drunk with three times three, and great applause.*)

The Ladies then retired, and

The following toasts were then given in succession:—

"Those numerous Members of the Legal Profession who evinced their freedom from prejudiced and self-interested feelings, by the support they afforded to Mr. Wakley in the late contest."

Mr. THEOBALD returned thanks.

"The Members of the Medical Profession who exerted themselves to protect the interests of their fellow-countrymen in the late struggle."—"The Committee."—"The Chairman."

The company did not separate till a late hour.

#### CLINICAL LECTURES AT ST. BARTHOLOMEW'S.

##### To the Editor of THE LANCET.

SIR,—I feel it incumbent on me to point out an error, or rather an omission, in the prefatory remarks of the last number of THE LANCET, where it is stated, that several gentlemen, there mentioned, are the only physicians and surgeons who regularly deliver clinical lectures in their respective institutions. Now, I can confidently affirm, that Dr. Latham, of St. Bartholomew's Hospital, who observes the greatest regularity in his attendance upon that institution, not only always stays an hour longer than is necessary for seeing his patients, for the purpose of descanting upon each case as circumstances may require, but frequently retires from the beds of the patients and dilates fully and unreservedly to the students upon their cases, in a manner which it would be well for other hospital physicians and surgeons to adopt. I am, Sir,

Your obedient Servant,

A BARTHOLOMEW PUPIL.

Sept. 29th, 1830.

## THE LANCET.

*London, Saturday, Oct. 2, 1830.*

THE reign of WILLIAM THE FOURTH, we are told, has commenced most auspiciously, and that a rapid progress towards improvement is already evident in several of the arrangements connected with the royal palace. Although many winters have not rolled over us, we have nevertheless lived too long, and have witnessed far too often, the deep root which misrule has taken, to believe that the axe will be applied with any degree of energy to the tree of corruption, by those who subsist in indolent ease on the baneful fruit which it so luxuriantly yields. Ingredients of a very dissimilar character often make an agreeable homogeneous compound; but forming an opinion of the whole from any one of its parts, might lead to a very unsound and erroneous conclusion. It were alike ungenerous and unphilosophical, therefore, to select any particular class of officers connected with the ministerial and household appointments of the Court of William the Fourth; for the purpose of condemning, or of throwing reproach upon, the character of the whole. And it certainly is fortunate for our Monarch that it is not allowable that his general discernment should be questioned from having failed, in an individual instance, to exercise a sound judgment. Were it otherwise,—were it permissible, to decide upon the whole of the appointments connected with the palace, from those of one department, we should state most unfeignedly, and without hesitation, that the public would have little to expect from the Court of our present Majesty, either calculated to command respect, or to call forth feelings of admiration. But it is to be hoped that motives similar to those which have influenced the appointment of the *medical* officers of the court, have not been in operation in any

other department. The profession generally is not only astonished, but it feels scandalized, by the selection which has been made. It is true the appointments of the greater part are merely nominal, and are unaccompanied by stipends; but, nevertheless, the public and the profession have a well-grounded right to expect that, as they are offices of honour and dignity, those gentlemen who are named to occupy them should be selected from the first rank of the profession, from those who have deserved well of their country, by the benefits they have conferred upon mankind. In rewarding and promoting the members of the law and the church, talents and public services, we believe, are generally taken into consideration; and, unless counterbalanced by circumstances of a peculiar nature, seldom fail to have due weight in the scale. But after the most mature consideration, after having carefully, deliberately, and impartially investigated the merits of the “ordinary” physicians and “extraordinary” surgeons who have been gazetted as the conservators of his Majesty’s health, we are utterly at a loss to form even a remote conjecture of the principle which can have governed the selection. The example is a bad one. In a country like this, where the minds even of professional men are tainted with no small portion of commercial spirit, every inducement, every stimulus, should be employed to incite to scientific inquiry and as mankind owes more of its happiness to the cultivation of medical science, than of any other, the public might indulge in a reasonable expectation that honour and preferment would be awarded to those meritorious individuals who have most contributed to its advancement. A country cannot be powerful, if its people have not health. A wise government, therefore, would do every thing in its power towards promoting and securing this most valuable of all national attributes. In this country there is scarcely any inducement for men of charac-

ter and talent to engage in the medical profession; at least, there are scarcely any offices of honour and emolument connected with it, and the very few that really do exist, are occupied through the operation of a system of favouritism and intrigue, which is as disgraceful to our Legislature as it is dangerous to the happiness of the community. Men of spirit and enterprise can but ill endure the cold and chilling repulse of unprincipled, undiscovering, and ungrateful preference. No man would for one moment attempt, by offering a single remark, to check the inclination of the Sovereign in selecting his immediate personal attendants; but the "ministerial" medical offices, and the honorary medical officers connected with the Household, the members of our profession, and the public, have a well-grounded right to expect should be occupied by men of established character and of acknowledged scientific acquirements.

We have now directed the attention of the public to the late medical appointments, and have thus paved the way for an exposure, which, we suspect, will not add to the respectability of a courtier, who is more feared than beloved, and who is the depository of too many secrets to be conveniently dismissed.

#### WESTMINSTER HOSPITAL.

It will be recollected that the late F. Holland, Esq., bequeathed 10,000*l.* each, to several of the principal hospitals, and amongst others that sum was given to the Westminster. In one of the bequests it was specifically appropriated to the building fund of the charity. No such direction having been given in the bequest to the building fund of the Westminster Hospital, the legacy, when received, was invested by the treasurer in the permanent funds of the charity, agreeably to the usual practice. At a subsequent period, however, direc-

tions were given by three of the medical officers of the charity, and another trustee, to invest this important legacy in the names of the trustees of the building fund! A most extraordinary step truly, and one so fraught with danger, that if permitted by the governors, the entire income of the hospital will be placed in jeopardy. A job is evidently in the contemplation of the medical officers, who ought not to be allowed to act as governors during the time that they are the servants of the institution. Neither at St. Thomas's Hospital, Guy's, nor at St. Bartholomew's, have the physicians and surgeons any such dangerous privilege; and it would be well for the interests of the Westminster Hospital, if the medical officers were deprived of the opportunity of being masters and servants at one and the same time. The question, we believe, is to be agitated on Wednesday next, when we hope the public will have reason to applaud the good sense of the great body of the governors of the hospital.

#### MEDICAL REFORM AT PARIS.

Amongst the numerous abuses which are now about to be remedied in France, the state of medicine will undergo a complete reform, and the Minister of the Interior has accordingly appointed a committee, in order to inquire into the present state of the hospitals, the manner in which the medical officers are elected, the appointment of public lecturers, etc., and to propose the necessary alterations. The committee consists of MM. Cuvier, Dubois, Duméril, Landré Beauvais, Andral, J. Cloquet, Husson, and Guérin, and is expected soon to make its report. The principal alterations will, it is generally hoped, consist in the adoption of the "canon" for all public appointments, the election by medical juries from the professors of the faculty, the medical officers of the hospitals, and the members of the Académie Royale de Médecine. The duration

of the professorship at the faculty will also, it is hoped, be limited to a certain period. We shall not fail to acquaint our readers with the more interesting points of the report as soon as it appears.

#### ELECTION OF SURGEONS TO THE NATIONAL GUARD AT PARIS.

A GREAT number of practitioners of Paris lately addressed a letter to LAFAYETTE, urging the necessity of appointing the surgeons to the national guard in a similar manner as in the election of its officers. They propose that the appointment of every "Chirurgien de Bataillon" be made by the practitioners of the quarter to which the Bataillon belongs; that the "Chirurgien-Major de la Légion" be elected by the practitioners of four quarters, and that the "Chirurgien en Chef" be elected by all the medical practitioners in the national guard.

#### SOCIETY OF "GENERAL PRACTITIONERS."

THE following address to the members of the profession has just emanated from this society. It is extremely well written, and, what is of still more importance, it evinces that high tone and spirit which should have characterised the first address, and the whole of the proceedings. We take some credit to ourselves for having applied "a bush to the wise that required it." Fully persuaded, as we are, that the members of this society are most anxious to promote the best interests of the profession, we have only to express our deep regret that they have commenced operations on so narrow and limited a scale; however, we have been given to understand that they will, should an opportunity offer, merge themselves, without hesitation, into a National College of Medicine,—a College which the demands of the profession have long called for in a voice of thunder.

## ADDRESS

### OF THE

"METROPOLITAN SOCIETY OF GENERAL PRACTITIONERS IN MEDICINE," &c. &c.

AN association has been established in London denominated "The Metropolitan Society of General Practitioners in Medicine and Surgery throughout England and Wales," the nature of which is developed by this, its first code of laws, whilst its more general intentions and objects are briefly explained in the following statement.

Medical men, in this country, whose services are dedicated to the practice of their profession through all its extensive ramifications of medicine, surgery, pharmacy, and midwifery, have been aptly denominated "General Practitioners." The epithet, as distinguished from the appellations which designate those individuals who devote themselves to one branch only of the healing art, is as honourable as it is descriptive; inasmuch as it denotes the possession of qualifications adequate to all the emergencies of an arduous profession. It has, however, been said, that, in its relation with the titles of "physician" and "surgeon," the term "general practitioner" implies a *subordinate* in the social and intellectual ranks of the republic of medicine; but such an inference is at variance with the spirit of the designation, and presents a forced acceptance of its sense, to which no individual of the class will subscribe. It will hereafter be the duty of the Association now established under the denomination of "The Metropolitan Society of General Practitioners" to discuss the subject, and, after due examination and deliberation, to confirm this or adopt another cognomen. It will also be the province of the Society to institute an inquiry into the expediency of equalising the right to professional distinctions, and to adopt such policy as shall secure for its members the civil and literary respect to which their education, attainments, and practice, entitle them.

The position in society occupied by general practitioners, is one that demands their serious attention. Perplexed by multifarious duties—threatened by extensive responsibilities—oppressed by physical exertions—disturbed by conflicting interests—assailed by jealousies—harassed by intrigue and envy—injured by corporate privileges—insulted by legal enactments—and degraded by an opprobrious mode of remuneration,—the general practitioner has more extensive evils to cope with than he can hope to combat successfully by the unassisted force of his own mental and physical exertions. It

is, therefore, a subject of astonishment, that the members of a class, around whose banner more than ten thousand individuals are spread over the cities and provinces of England and Wales, have not sooner coalesced, and formed themselves into a deliberative body with executive authority and means, in order to render the knowledge, experience, and resources of the entire mass available to every member of the Association, who might seek or require its advice or support. By such a union, a concentration of the opinions, experience, talents, and influence of the whole class would be consummated, and its application directed, upon all occasions, to the necessities and emergencies of any individual; or to the promotion of the collective interest of the whole body. In aid of a co-operative system like this, the support derived from a pecuniary fund is not to be overlooked; in fact, it is an indispensable requisite for carrying into effect any political or legal undertaking—for defending individual interests—and for supporting a domiciliary establishment, which, to ensure success to the scheme, should offer, not merely a place for the conduct of business, but the conveniences for agreeable social intercourse.

Upon the foregoing principles has the Society of General Practitioners been begun; its prosecution may be understood by the following details:—

In the selection of a house for the Society's use, the Committee have been influenced by a prudent regard to economy, and a desire to restrict the extent of the chambers to the actual necessities of the Association. The Committee did not consider it justifiable, in the onset, to open an establishment upon a large scale, purposing to extend it, whenever an increase of the Society's numbers renders it necessary, or the members themselves may call for further accommodation. Such refreshments as can be prepared under the present circumscribed fitness of the premises, are served (at a moderate charge) at any time during the day, by the persons in attendance. It is in contemplation, however, to provide dinners and other refection, as soon as the magnitude of the Society will warrant the adoption of a plan for combining the comforts and conveniences of a social club with the more solid advantages to be derived from the Institution. The reading-room is open from ten o'clock in the morning till ten at night, and the daily newspapers, periodical journals, &c., regularly laid on the table. Notwithstanding the library offers at this time but a limited allurements, the Society has cause for congratulation in the prompt and handsome manner in which many eminent individuals, not belonging to the Association, have presented their works. The

members of the Society, also, have not been tardy in offering their respective donation of books. The library will be opened as soon as the necessary arrangements are completed.

The Committee have great pleasure in announcing, that the treasurer's statement of the Society's affairs shows a balance of cash in hand; and they take this opportunity of giving a pledge to its members and to the profession at large, that they will, on no account, incur any liabilities beyond the actual resources of their funds.

The pleasure and advantages to be derived by the metropolitan surgeons from the social and friendly intercourse established and confirmed through the medium of their chambers, are too apparent to need any comment; to the country members, also, they present a most convenient place of resort during their occasional sojourn in London, where they may meet their professional friends, mix with their unknown contemporaries, and, at leisure, contemplate the men, books, customs, manners, opinions, and feelings, of the medical microcosm of the metropolis. The associates, likewise, join in these literary and social meetings, forming and cementing those professional ties and private friendships which ought to subsist between all the members of a liberal profession. To the student in medicine, also, the Society's chambers afford peculiar advantages. He is supplied with books either of reference or general instruction; he has the accommodation of a comfortable room for meeting his friends, for his moments of leisure and relaxation, or literary studies; and, lastly, in addition to the mental and scientific improvement which he derives from attending the discussions of the Society, he associates daily with his seniors in the profession, from whose conversation and communications he receives both pleasure and instruction.

The amount of the annual contribution, in comparison with the advantages to be derived from it, has been fixed at a very moderate sum, the Committee feeling assured that the numbers of the Society will be equal, even at this small ratio, to the production of a fund amply sufficient for all the purposes required. The first care of the Society is the conservation of its own integrity, and the general interests of its members. Medical politics have decidedly taken a bias unfavourable to the general practitioner, and he stands, not only unprotected in his professional character by the fostering hand of a generous government, but legislative enactments have actually been passed which oppress and degrade him; his privileges are trampled down by the assumptions of unjust, self-created, arbitrary power, and the defence of his rights con-

founded by the hazardous jurisprudence of legal misinterpretation. These great and crying evils can only be redressed by parliamentary influence; and the chief strength of the fund arising from the contributions of the members of this Society, lies in the power which it gives of appealing to the legislature, and of persisting steadily against oppression and opposition until the general practitioner shall have obtained a distinct and legal recognition of his rights, privileges, and rank, and have burst every trammel that binds him down to a degraded subserviency. These are measures which the Society is pledged to pursue; the period of their commencement must, of course, depend upon the possession of means, and be fixed by the fiat of deliberation. For the purposes of individual protection, the fund will at all times be available in every instance where, upon due inquiry and examination, it shall appear to the Society, that one of its members sustaining any injury or wrong in his professional capacity, or is called on to assert his right, or defend his interest on any point that applies strictly and especially to the whole body. The subject of professional remuneration is of momentous urgency, and demands the most careful consideration. It is true that under the direction of the Lord Chief Justice Tenterden, a verdict was lately given in favour of the right of a general practitioner to charge for his services; but such a decision by no means necessarily becomes a law of the land, and though dictated by the opinion of one judge to-day, it may be reversed by the dictum of another to-morrow. When the Society shall have arranged a scheme for regulating a general mode of professional compensation, by which the medical practitioner may be emancipated from the odious necessity of balancing his remuneration by the charge for his medicines, it will be necessary to legalize the measure by an application to Parliament. In fine, the fund formed by the annual contributions will enable the Society to prosecute measures for obtaining such legislative interference as may be necessary in removing all disabilities, for the protection and support of the interests and welfare of its members, for bringing into operation those suggestions which the fluctuating influence of circumstances may give rise to, and for establishing the respectability and prosperity of the general practitioners of this kingdom.

The plan of the benevolent fund differs from any other heretofore established,\* being founded upon the principle of general benevolence. To the members of this So-

ciety, whose circumstances preclude them from providing for the contingencies of accident, old age, and death, it must surely be a consolation to contemplate a resource for such periods of desolation, whilst the more favoured individuals whom fortune has placed above the necessity for such aid, will not withhold their support to the efforts of humanity. It is therefore confidently trusted that the voluntary donations of all classes of persons will not fail to produce a fund adequate to the benevolent intentions of its philanthropic contributors, in aid of which the surplus of the general fund will be added to it as often as it exceeds the sum necessary for the exigencies of the Society.

To promote the objects contemplated by the founders of this Society, its members, wherever situated, are invited, at all times, to an unreserved communication of their opinions and wishes. By this means a splendid system of general co-operation will be established throughout the kingdom, and remedies devised and applied for evils of every sort, whether local or universal, individual or collective. In furtherance of the measures for improving the science of medicine, it is requested that the members will transmit to the Society in London, such papers, reports of cases, and other professional information, as they may consider conducive to the improvement of knowledge and the good of the public. The more important communications will be printed, as the "Transactions" of the Society; and as the literature thus collected will be regarded as the joint property of the association, it will be published for the benefit of its members; merely at a remunerating price for the expenses incurred.

Such are the principles and intentions of a Society to which all the general practitioners in the kingdom should attach themselves; and every individual of the class is hereby invoked, by the respect which he bears for himself, and the regard he entertains for the honour and interest of his profession, to give his aid in promoting the formation of an institution for establishing the prosperity and happiness of the medical community.

"Ex veritate causa pendetur."

By order of the Committee,

HENRY BOND, Secretary.

Society's Chambers, 4, Regent Street.

\* Extending relief to medical men who do not belong to the Society, and are not subscribers to any fund.

*A Treatise on the Nature and Cure of those Diseases, either Acute or Chronic, which precede change of Structure, with a view to the preservation of health, and particularly the prevention of Organic Diseases.*  
By A. P. W. PHILIP, M.D., F.R.S., &c.  
London: Longman and Co. 1830. 8vo. pp. 432.

It is much to be regretted that an author who has written so much and so well as Dr. Philip, should at last put forth a work like the present, the value of which, to say the least of it, is very questionable, and which can certainly add nothing to his reputation. A large portion of its contents consists of observations already repeatedly published by others, and facts with which every practitioner is acquainted; and the rest is, for the most part, taken from the author's previous publications, to which continual reference or allusion is made. There is little or nothing, therefore, in the work which can be called original, nor is this defect in any way compensated by convenience of arrangement or clearness of reasoning; on the contrary, many parts of it are written in language and style so obscure and confused as to be almost unintelligible to the medical, and entirely so to the general reader, for whom nevertheless, as the author has stated in his preface, it is at least equally intended. These remarks, it is true, apply more to the first part of the work than to the second, which contains observations on the treatment of the diseases in question, yet even here, mingled with some excellent directions to invalids with regard to diet and management, there is much which can be serviceable neither to them nor to any class of readers whatever.

Under these circumstances it would be altogether useless for us to make any long extracts, or to give any analysis of the work; there are, however, some particular passages which we cannot pass over without notice.

At p. 49, the author states that "we have every reason to believe that the sensorial is a power wholly distinct from that strictly called nervous." In the following page he enumerates sensation and volition among the "sensorial functions," and yet immediately afterwards observes "the following may be regarded as the nervous functions

properly so called, the excitement of the muscles of voluntary motion, by which, through the intervention of the nervous system, they in their usual functions are subjected to the sensorial power," &c. There is some confusion here between the words "power" and "function;" if they are not regarded as having a similar import, then the whole passage is unintelligible; and if they are, it then surely contains a manifest contradiction, for the "excitement of the voluntary muscles" is certainly an act of volition, and ought, therefore, according to the author's division, to be placed under the "sensorial functions." Throughout the whole chapter, indeed, on the functions of the nervous system, there is much obscurity and apparent contradiction, and if Dr. Philip himself understands these subtle distinctions, he has certainly failed in enabling others to do so. Why, for instance, "the nervous power is not, strictly speaking, to be regarded as one of the vital powers of the body," we are at a loss to comprehend; for the reasons which are adduced in support of this statement, if they have any force at all, will equally apply to all the other vital powers; and so far are we from agreeing with Dr. Philip, that we are rather inclined to reverse his statement, and to say that, strictly speaking, the nervous is to be considered as the only vital power, the principle which presides over all the functions of the body, and on which they all more or less depend.

Although much is said of the diseases of the heart and lungs, no notice whatever is taken of the stethoscope, except in the following sentence, which occurs quite at the end of the book.

"Nor are we assisted either by sounding the chest, by gently striking different parts of it, or the use of a lately-invented instrument; for although either of these means readily points out where and to what extent the lungs are obstructed, neither will tell us whether the obstruction arises from tubercles or other change of structure, or thick and viscid fluids clogging the air-tubes and cells."—p. 399.

The incorrectness of this statement must be very evident to any one but moderately accustomed to the use of the stethoscope, the author's ignorance and contempt of which are shown in other parts of the book, where statements are made relative to the

diagnosis of thoracic diseases, quite at variance with the results afforded by this valuable instrument, and which ought, therefore, at any rate to have been given in a somewhat more qualified manner.

Such strange phrases as pulmonary consumption being the *cause* of organic disease of the lungs, the *brain* being the *organ* of feeling, &c., may possibly be regarded as mere typographical errors; but what shall we say of the following sentence?—"They (the diseases of the heart) may be divided into two classes, those which weaken the power with which it propels the blood, and those which impede the passage of the blood through it; the former the diseases of the heart itself, the latter of its orifices and its valves."—p. 136. Of inflammation and of nervous irritability, it may perhaps be said, that they, if not immediately yet ultimately, have the effect of weakening the action of the heart, but this cannot apply to hypertrophy, in which the heart will continue to act with great violence, producing a full and strong pulse even for many months; and thus one of the most common of the organic diseases of the heart is entirely excluded from them.

But we have had enough of this ungrateful task, and we shall conclude our observations by extracting one short sentence which is equally true and important.

"Thus all the important tendencies in the cases we have been considering" (of disease in one organ inducing similar and different diseases in others) "depend on the direct influence of the nervous on the sanguiferous system, on the fact that continued nervous irritation always tends to produce inflammatory action."—p. 217.

---

"ARGUMENTS" IN FAVOUR OF THE PRESENT "ORDER OF THINGS" IN THE MEDICAL PROFESSION.

To the Editor of THE LANCET.

SIR,—For the satisfaction of some secret doubts, I beg to know whether the letter, in the last number of your journal, "in favour of the present order of things," was the genuine production of a Licentiate, or only a "solemn sneer" with which you sapped the pretensions of the "superior portion of medical men." If the former supposition be true, I hope, Sir, that the practice of your correspondent is far sounder

than his arguments; for, if it be not, the class of practitioners who are inferior to him must be contemptible indeed.

I would willingly make some remarks upon that letter, but am almost restrained by a serious doubt of its genuineness. Surely, Sir, no educated man can question your right to censure any evil, because you are not its personal victim. Such an opinion, if any one could entertain it, would be immediately refuted by the maxim, that "he who allows oppression, shares the crime." But, in civil society no evil can be entirely personal, we have all a common interest in destroying bad customs, and therefore the right to do so is common also. Let the "Licentiate" remember this, when he again wishes to intrude his imbecility upon your pages.

The "dinners and entertainments" to which your correspondent alludes, are certainly of a more substantial nature. But, Sir, are they not provided rather to ensnare the patronage of the apothecary, than to recompense him for it? If they are truly given in "return," the recompense is not very magnificent; it is only an occasional repast to those men from whom the physician virtually receives his daily bread. It is the generosity of a highwayman, who gives a shilling to the man whom he has plundered of a purse.

I do not see the applicability of that simile, which your correspondent has taken from the military profession. The distinctions in the army are natural and essential, the officer plans and directs that which his underling has to execute; but no such distinction can be formed in the medical profession, unless the "inferior portion" of it be confined to the mere preparation of prescriptions. If any such distinction should ever be made, our "superiors" may be confident of deserving, even if they should not obtain, the mechanical department.

As regards the fine of 100*l.*, if any such fine there be, the apothecary is in no danger of incurring it. His resistance will not be shown in an intemperate refusal to prepare the prescriptions of the physician; but in a gradual and rational influence over the mind of his patient. No penalties can punish such an opposition, and no paltry machinations can defeat it. When the zeal and ability of the general practitioner are fully known to the patient, he will have but little inclination for the ceremony and expense of a physician. Old prejudices in favour of a name will be easily and effectually removed by the remonstrances of reason. And as this is the kind of opposition which best befits gentlemen, it is that which will most probably be adopted. Let the "Licentiate and his acquaintances" abandon, therefore, their premature hope of he-

coming common informers; or refrain, at least, from publishing such a disgraceful intention.

If it be your opinion that these remarks may serve any good purpose, they are, Sir, at your service.

Your faithful servant,

J. C. J.

Blackfriars Road,  
September 12th, 1830.

[We hope that upon reflection, our correspondent will find in the character of this Journal sufficient evidence for assuring him of the authenticity of the document to which he has referred.—ED. L.]

#### TO THE PARENTS OF YOUTH DESTINED FOR THE MEDICAL PROFESSION.

GENTLEMEN,—Having been for many years an attentive observer of the state of the medical profession, and of the qualifications of the juniors who are commencing the practice of it, it has appeared to me, that in very many instances the education of these young men has been upon too contracted a scale, as regards the acquisition both of general and of professional knowledge. The general diffusion of science, "the march of intellect," if you please, is such among all classes of the community, as to compel those members of our profession who are desirous of upholding the honour and dignity of it, to exert themselves in keeping up our title to the pre-eminence which is so kindly conceded to us in society; and in taking care that we at least keep pace with the members of other professions in intelligence—in the possession of various knowledge, as well as of that which is directly essential to the practice of our art.

With this view, I would beg leave to recommend, that the preliminary education of our juniors should be more liberal and comprehensive than it generally is; that boys before they are apprenticed, should be well grounded in classical and polite literature—in the elements of the mathematics, and of natural philosophy.

In the accomplishment of this purpose, youth will commence their professional studies with great advantages: with well-regulated and disciplined minds; the faculties expanded and strengthened by having been accustomed to vigorous application, and therefore qualified to apply their powers with greater effect to the acquisition of the medical sciences, and those branches of knowledge which are immediately auxiliary to them.

That these are important truths, must, I think, be acknowledged by every candid and competent observer. Similar opinions have

been so admirably expressed by an able writer in a recent publication, that I beg leave to quote as follows:—

"That a young physician should commence his practice by becoming a professor of ethics, may, to some, appear an extraordinary mode of introduction to eminence in the art of healing. Few, however, have attained more practical skill, more intimate acquaintance with their own peculiar science, or more deserved success, than Pringle. To suppose that general attainments in knowledge, and even a predilection for polite literature, have a tendency to disqualify or enfeeble the medical practitioner, is to avow an ignorance of the character and private history of the most distinguished men who, in every age and country, have improved and elevated that profession. Variety of knowledge was never seen to encumber the possessor; on the contrary, it prepares an ampler space and a firmer footing for all that is to come after. In the numberless and unexpected emergencies which occur in the relief of the diseases of the body and the mind; in the ever-varying combinations of causes of character which present themselves, an almost universal acquaintance with nature and art would seem to be demanded. The power of making good observations, a retentive memory, a fixed attention, and the habit of generalizing, are among the most important qualities of the physician; and these can be acquired or strengthened, only by an early and extensive intellectual education. Some of the most enlightened governments of Europe have perceived this truth during the present century, and now exact from the candidate for medical honours, a course of more or less rigorous preliminary studies in general literature: we may cite France and Prussia in particular?"\*

In the great object of raising the standard of intellectual and professional attainment in our profession, I am of opinion that the University of London is likely to be eminently instrumental. Within its walls are taught all the branches of useful knowledge that enter into the composition of a polite and liberal education, and there youth, previously well initiated, will acquire a taste for dignified and intellectual pursuits, and become, eventually, valuable members of the profession, and men of enlightened minds. As a school of medicine, this university has already a high reputation, which will doubtless go on increasing under its eminent professors. Certain it is, I believe, that exertion must be made to extend and enlarge the education of youth intended for the medical profession, as regards early mental discipline, and the acquisition of

\* Lives of Eminent British Physicians—Pringle.

preliminary, as well as of professional, knowledge, if we are to maintain our position in the present advanced and advancing state of civilized society.

Yours, &c.

SURRIENSIS.

ARMY ASSISTANT-SURGEONS.

To the Editor of THE LANCET.

SIR,—Your correspondent R., whose letter appears in the last number of your invaluable publication, ought to have known that the late Secretary at War has made an effort to remedy the evil complained of by R.; and almost the first act of his present Majesty was to sign a royal warrant giving to assistant-surgeons of the army, after ten years' service, the daily pay of *ten shillings*, and allowing them also a retirement proportioned to their services on full-pay. But, Sir, how melancholy the reflection that the junior officers of this department should owe this boon to the good heart and sound judgment of Sir Henry Hardinge, and not to their own natural chief Sir James McGrigor! From the moment this latter gentleman got placed at the head of the medical department, up to the present hour, I defy his most favoured or partial friend to point out one act of favour or of advantage he has procured for the department, or any exertion he has ever made to improve the condition of medical officers, or to render them more respectable. He has, indeed, attempted to rule them with a rod of iron, and, where he could with impunity, has shown that Rob Roy's blood runs in his veins. But no-where under his government can I discover any-thing like the act of a noble mind, or the generous feelings of one who by good luck more than talent owes his fortune and his respectability to the service. All McGrigor's efforts have been for self, and the shameless manner in which his influence has been used to serve his son and heir, would have brought many before a court martial.

King William has increased the pay of all the medical officers in the army, and has arranged their ranks in a way that is more uniform, and gives a greater respectability than has hitherto been the case; and instead of being dressed more like monkeys than men, they have again been permitted to assume the British uniform. But I really believe, had it been proposed that the doctors should be dressed like "Paddy from Cork" with their coats buttoned behind, his honour the Knight Director General would have said, "Oh! by all means let it be so." I should be glad to see the new warrant for regulating the medical department of the army in the pages of THE LANCET, as no otherwise do I conceive can it become generally known to the profession.

I am, Sir,

Your constant reader and admirer,

A POOR ASSISTANT-SURGEON.

September 13, 1830.

PAY OF ARMY MEDICAL OFFICERS.

To the Editor of THE LANCET.

SIR,—I beg leave, with reference to the communication signed R., and inserted in No. 367 of your Journal, to forward you a statement of the rates of daily pay of army medical officers annexed to his Majesty's warrant, dated 29th of July, 1830 (from which day the same is to take effect), by which you will perceive that the benevolent wishes of your correspondent have been anticipated.

I am, Sir,

Your obedient servant,

J. H. P.

Sept. 15, 1830.

P.S.—There are, of course, other particulars in the warrant, but as the scale of pay contains the information relative to the increase of the assistant-surgeon's emoluments, I have thought it best to occupy the least possible space of your valuable work.

# RATES OF DAILY PAY.

RANKS.	RATES OF DAILY PAY.			
	After 25 Years actual Service.	After 20, but under 25 Years actual Service.	After 10, but under 20 Years actual Service.	Under 10 Years actual Service.
Assistant-Surgeon.....	£. s. d. 0 10 0	£. s. d. 0 10 0	£. s. d. 0 10 0	£. s. d. 0 7 6
Regimental ditto .....	1 2 0	0 19 0	0 15 0	0 13 0

Deputy Inspector General of ditto .....	1 10 0	1 8 0	1 4 0	—
Inspector General of ditto	2 0 0	1 18 0	1 16 0	—

## UNJUSTIFIABLE OPERATIONS.

To the Editor of THE LANCET.

SIR,—Allow me a small space in columns which have never yet been closed to any appeal on behalf of suffering humanity. I entreat the attention of overseers and guardians of the poor to a practice which has gained ground to an alarming extent; I mean the dismemberment of the poor in parish workhouses and infirmaries. It is the custom in these places to do what is never done in large hospitals, namely, to perform mutilating operations at the instance of one individual—the operator, without the consultation, sanction, or concurrence, of any other practitioner.

Before any operation be undertaken (except for hernia), I think that it is the duty of the lay authorities to receive the most satisfying and convincing proofs of such necessity from more than one competent authority.

I remain yours, &c.

A FRIEND TO THE POOR,

And an Enemy to all close Hole-and-Corner Proceedings.

Sept. 2nd, 1830.

## ANTIDOTE TO PRUSSIC ACID.

MR. W. H. POTTER, of Old Compton Street, has forwarded to us some observations with a view "to corroborate the use of chlorine as an antidote to the deleterious effects of prussic acid," and adds the following experiment:—

"I prepared a concentrated hydrocyanic acid, of the specific gravity of 89, at 60° temp. Fahrenheit; I placed one drop in the eye of a cat; she walked about in a staggering manner for the space of a minute, she then fell on her side, and was convulsed; her eyes appeared large, and starting; the pupils much dilated, fixed, and covered with a kind of glaze; her breathing was deep and laborious. Chlorine was now administered, diluted with several times its bulk of water; a few drops were placed in her mouth, and plentifully scattered round about. It seemed for some time to produce no effect, but, by using it assiduously, and *splashing the animal with cold water*, sense at last returned, and she turned her head to where the bottle containing the chlorine was held. Respiration now became more regular, with starting and throwing out of the limbs; the animal seemed to pant for the fresh air, and to take as large inspirations as possible. After about an hour had elapsed from the exhibition of the poison, water was placed under her nose,

when, as by the influence of magic, before it could be let down from the hand, she seemed suddenly to resume all her powers, started up, ran several yards, and hid herself." The cat entirely recovered in four or five hours.

Our correspondent does not seem to have borne in mind, that cold effusion has been recommended as of itself sufficient to counteract the effects of hydrocyanic acid, and that the conclusions at which he would arrive in favour of the efficacy of chlorine in this case, are completely neutralized by his employment of the water. In a previous volume of this Journal, he will find an account of the results obtained by Dr. Herbst, of Gottingen, who first recommended the shock of cold water, and practised it on animals most successfully. His experiments have been repeated by Orfila with similar effect.

## DERBYSHIRE INFIRMARY.

To the Editor of THE LANCET.

SIR,—I think you will like to hear that a long discussion took place yesterday (Monday Sept. 27th) at the Weekly Board of Governors of our Infirmary, as to the necessity of calling on the coroner for the borough of Derby, to inquire into the cause of the sudden and unexpected death of one of Dr. Baker's patients; but after much argument, particularly from a limb of the law on the doctor's side, the Board agreed that they could not inform the coroner, *without causing an imputation against the doctor*, and it was therefore very considerably determined to let the matter rest! The house apothecary, the apprentice, and some patients, were examined before the Board, and the cause of death did not appear. We thought of "the pent-up-house of darkness;" we did just manage to collect, that the deceased was a woman of middle age, who had been treated for a tumour in the belly, had been "rubbed" with iodine ointment for *three days*, and the plan *changed*, but death stopped the intended course of *physic*.

The woman was extremely sick for two days before death, in short nothing would stay upon her stomach, and the apprentice said "there was a good deal the matter with the stomach;" we have heard the stomach was in a highly inflamed state, as much so as if poison had been taken; the woman looked of full habit of body, and the tumours did not give her "much trouble;" we understand she had not been treated for inflammation of the stomach, either by general or local bleeding, or by blistering the pit of the stomach. Hence these questions arise, What caused the inflammation? and why were no

remedies used to subdue it? was it overlooked, and all the attention directed to the indolent tumour in the belly? Dr. F. Fox told the Board, he suggested at the examination of the body after death, that there was as much reason for preserving the inflamed stomach, as for keeping the tumour, when Dr. Baker immediately exclaimed, "I will not allow any impertinent interference, for I do not wish to have my cases cooked up for the Lancet;" so the crimson stomach was sewed up in the body to be covered by the sod! We think this case wants no cooking.

We do not know what physic this stomach had received, but we think the doctor should be looked after, in his doses at least, since he ordered two teaspoonfuls of compound colicium powder to be taken three times a day by one of his out-patients a short time ago, but the man had sense enough to discontinue the dose before he had repeated it so as to produce any *very serious* effects upon his constitution. This compound contains eight grains of the powdered colchicum-root in half a drachm, the rest being sulphate of potash.—N.B. Two teaspoonful not much heaped up, weigh more than THREE DRACHMS, so the doctor ordered his patient forty-eight grains, at least, of the colchicum-root for a dose, terdie! The pharmacopœia of the hospital states the dose of this compound to be from *one scruple to half a drachm*; it would be well to know the particulars of this colchicum case,—must not the patient have had a very fortunate constitution?

The fishes get no physic now (thanks to Mr. Wright). Dr. Baker seldom changes his medicines, and his out-patients do not repeat their attendances as they used to do before "the smell of gunpowder." The physic bill this quarter is about 30l. instead of 88l. What will the druggists think of this? They must look for assistance from the self-supporting dispensary now getting up in this town, where patients are to be doctored for a penny per week! Midwifery, 7s., paid two months in advance!

PHILANTHROPIST.

### COUNCIL OF THE COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—In your able observations on the Council of the College of Surgeons, wherein you have introduced my name, you truly intimate, that there "is a point beyond which human endurance cannot go, and whence reaction springs." I feel the justice of your remark, "that when the yoke of tyranny is felt upon the neck, a man, if

ever so enslaved or debased, is stimulated to shake it off." I am not one of those tame spirits who will silently submit to gross injustice; I have been treated with such by the Council of the College of Surgeons, therefore I shall send you a few letters for the information of my professional brethren, and the public at large, stating their proceedings against myself, and four other members of the College, to whom they have thought proper to deny their covenanted rights. My name stood first on the list of those declared, by the preceding meeting of the Council, to be perfectly eligible, in point of talents and abilities; it was followed by Mr. W. B. Lynn, Mr. Harding, Mr. Broughton, and Mr. Jessy. The form of ballot was gone through, I believe, in the three first cases, but that was deemed too troublesome in the two last, in their indecent haste to get to the *little person*, Mr. Earle, whom the commanding influence of the old man of the council had pre-arranged should be brought into it. Of qualifications I have yet to learn, that Mr. Earle possesses one that is not equalled, if not surpassed, by all the gentlemen over whom he has been *unjustly* placed. For myself, I fearlessly assert, that my professional education has been such as few men have been fortunate enough to enjoy, and certainly such as few members of the Council can boast of; for, after having studied in the London schools of anatomy, surgery, and medicine; attended as pupil and house-surgeon for two years one of the London Hospitals; passed my examinations, and received my diploma from the College, I spent three sessions in Edinburgh studying medicine, and one anatomical season in Dublin, and have since visited Paris with a view to acquire the knowledge of any improvement in the healing art that our continental compeers may have made. I have only to add, that my school and hospital-acquired knowledge has been fiated by an experience of twenty-four years' active practice in different parts of Europe, part of which time was passed in the Peninsular army, where the great operations of surgery became matter of daily practice; and that I have now been some years settled in London, in a not very confined exercise of our honourable and useful art. Thus I beg to demand, in what single point does Mr. Earle possess an equal claim with me for the honours which, by the by-laws of the College, I am justly entitled to? One single point may be urged, viz., that he is the nephew of the late Mr. Earle, and fortuitous circumstances have made him the successor of his *uncle* at one of the hospitals. For a moment allow this title of his to be fatal to my claims; Mr. Lynn's claims on this point are equal to Mr. Earle's, but he too is passed over by the Council of (should

be) just and honourable men. Mr. Earle, a *junior* member of the College, is dragged over the heads of his five *seniors*, and *more experienced* professional brethren, by the secret conclave, who machinate at midnight under their dark corporate mantle, assassinating the character of any individual member of the College before whom they may choose to exercise their private professional jealousy and malignant spleen! And who are these men that have thus dared to commit such flagrant injustice? I will endeavour to give you fearlessly and truly the best information of each individual that I am possessed of.

The President, Mr. Headington, is a scholar, a high-minded, independent, and honourable gentleman, and of great professional acquirements. Of the two Vice-Presidents I can say little as to high-mindedness, independence, or great professional acquirements. They appear to me to have been fortunate in a successful worship of, and bowing to, persons, but that the homage has been much devoted to the sciences I shall not be bold enough to assert, though they may have sacrificed very largely to the graces, and even to the muses. Of Sir William Blizard I could wish to say much; but there are *causes* which operate on organised beings, and some which place all moral consideration in abeyance; not that I think the *good* Sir William Blizard has ever suffered under *restraint*, which, however morally good, might be considered a physical evil. But, Sir, I have a great idea, that had Sir William put under *restraint* his *feelings*, they would not have got the better of him so altogether, as they have been known to do in the course of his long life; and his *FAMILY*, and the few enlightened members of the Council, would not have suffered from his *talons* those ugly scratches which they have occasionally received, when he has been in a desperate fit of that terribly wicked disease, the mania senilis, under which the *good* Sir William has so long laboured, although some of his warmest friends still assert, that the disease has not impaired his intellectual faculties, which, they say, are as bright as ever. As to that fact I cannot speak, but I pray God to keep me from such praise from *my* friends, because I did hope, in mercy to his weaknesses, that in early years the *good* Sir William did possess more vigour of mind and body than he at present retains. How is it, I may be asked, that he has still such influence over the Council; is it that intrigue is a part of the disease under which he labours? or that eternal fidgetty do-nothing, that every man feels when the gulf of death yawns before him? Or is it that respect for senility which the members of the College were called on to exercise at the Hun-

terian orations delivered two or three years ago? It is one, it is all; such an exhibition as the latter would not be permitted in any scientific institution throughout the civilized world! because the colleagues of such a man would have boldly and independently interfered to prevent any fellow man making such a public exhibition of the decadence of his powers! But the peculiar constitution of the council is inimical, most especially, to independence; for half the members of the council are aspirants for the honour, and, more important still, the emoluments, of the examiners; to this goal they cannot arrive but by courting and flattering, therefore any canvass that is refused by one of the council to an examiner, is never to be forgotten, when said councillor aspires to become a member of the court of examiners. Thus sycophancy and subserviency to what has long been considered the head, the old man of the college, are encouraged. I put it to the profession at large, Is such a head, said to be, 93 years old, fit to guide and direct the numerous members, much less to advise the legislature, on all matters connected with the health and preservation of his Majesty's liege subjects?

In my next letter I shall proceed to give you a little information of the other members of the council individually. Indeed their neglect of duty as a body is most apparent:—they were appointed to watch over the interests of the public, and the profession; how they have fulfilled this great and important duty, may be seen in a thousand ways; one in particular I recollect. Mr. Peel ordered a commission from the council of the College of Surgeons, to sit upon the state of Ilchester jail; three of its members went down, staid there three or four days, made their report, and accompanied it with a demand on the *public purse* of *seven hundred and fifty guineas*! which Mr. Peel, I believe, *reluctantly* was obliged to give an order on the treasury for, to be paid out of the taxes of the people. If this tale is not strictly true, Sir William Blizard can tell, as he was one of that *disinterested, virtuous* triumvirate, who pocketed his full share, to the eternal disgrace of the profession generally, and to the college in particular.

Never was a more disgraceful act, in my opinion; for, if those men did not deem it a part of their college duty, for which they receive five or six hundred a year, they should at least have looked to the corporate funds of the college, which amount to 80,000*l.* rather than have demanded it from the treasury of an over-taxed people.

I am, Sir, yours, &c.

J. R. ELMORE.

9, New Cavendish Street,  
Portland Place.

## ST. BARTHOLOMEW'S HOSPITAL.

## TRAUMATIC TETANUS.

EDWARD HESAN, labourer, aged 29, admitted into St. Luke's Ward under Mr. Vincent, on Saturday, 25th September. The terminal phalanx of the index finger of the right hand was severely lacerated; the integuments divided along its outer side and across the articulation; the bone fractured, and its ligamentous connexions extensively torn. The middle finger of the right hand was also slightly injured. He stated, that the injury had occurred that day, and resulted from the fingers having been caught in a windlass, at which he was employed. His health, previous to the accident, was very good, and the several functions were regularly performed.

Some difference of opinion, we understand, arose as to the propriety of at once amputating the injured phalanx. This measure, however, was not proceeded with, and the common poultice was applied. Under this treatment suppuration ensued, and on Tuesday morning, 29th September, the wound discharged abundantly, and looked well. The bowels were at this time rather torpid. During the day he complained of pain from a "gumboil," and difficulty of deglutition; but this circumstance escaped particular notice till the evening, when it had become more severe; the internal fauces were relaxed, and rather tender to the touch, and the back of his neck was stiff, uneasy, and slightly swollen. The sister gave him an alum gargle, and rubbed his neck with the common liniment.

29. Rested badly. At seven A.M. was suddenly seized with a violent tetanic spasm, assuming the forms of trismus and episthotonos. After the spasm had continued some time, the house-surgeon was called, who directed a drop of croton oil to be repeated every two hours, till the bowels should be relaxed. From that time several spasms occurred, until Mr. Vincent's visit at half past twelve o'clock. The wound was then found dry and pale; the countenance anxious; breathing oppressed and hurried; the neck and abdomen tender to the touch; pulse quick and rather full. Croton oil had not operated. Mr. Vincent ordered the patient a warm bath, two drops of croton oil every second hour till dejections should be procured, and drachm doses of laudanum also, every second hour. The red precipitate to be applied to the wound.

30. Eleven A.M. Seven drops of croton oil taken, and two common injections administered at alternate periods. Four doses of laudanum used. Bowels scantily moved by the croton oil; injections returned as soon as given. Has slumbered at intervals since

the second dose of laudanum. No tetanic spasms through the night, but had one at seven A.M., and another about ten A.M., but of less severity than before.

One, P.M. No recurrence of spasm; pulse 120, full; breathing hurried; coughs much, with viscid expectoration. Complaints of thirst, but experiences extreme difficulty in deglutition, and the fluids enter the larynx, exciting great distress. The face is flushed, and the conjunctivæ injected; the tongue clean, but dry; skin warm and moist; less tenderness of abdomen; but the neck still feels stiff, and the lower jaw can with difficulty be relaxed. The sternomastoid muscles are prominent and rigid; he trembles much, and his countenance is expressive of great anxiety. Croton oil and injections to be repeated as before, and the same doses of laudanum to be resumed if the spasms should recur.

Two, P.M. Another episthotonic spasm has just taken place, which lasted three minutes, exhibiting the usual phenomena, but with diminished violence; mental functions completely undisturbed.

When we returned, at four P.M., he had just expired in a spasm, a few minutes after leaving the warm bath.

## WESTMINSTER HOSPITAL.

## REMOVAL OF AN EXOSTOSIS OF THE NASAL BONES.

JOHN CHAER, about 30 years of age, a chimney-sweeper, admitted 16th August, under Mr. Lynn, with fungous growths arising from the palatal plates of the superior maxillary bones, extending downwards into the mouth, and upwards so as to fill almost entirely the inferior meatus nasi; an excrescence of the size of a marble occupied the situation of the left lacrymal sac. An exceedingly foetid smell emanated from the mouth and nares. He was ordered by Mr. Lynn to have the parts washed with warm water, and the bowels well and regularly opened. The lad gave this story of his disease. A year ago, whilst at play, he received a scratch of a finger-nail in the septum of the nose; the inner parts of the nose swelled and became painful, and the passage of air through the nasal meatus was much impeded. Whilst in this state, he received a violent blow on the nose when in a crowd. The painful consequences of this compelled him to apply for relief to a parochial infirmary, where many and various remedies were resorted to without effect, and the disease gradually took its existing form.

Aug. 22. Mr. Lynn determined to remove the fungous excrescence from the roof of the mouth with a scalpel. The boy was for that purpose brought into the theatre, and the

judgment of the surgical officers required. This being in the affirmative, Mr. Lynn having depressed the upper jaw to the utmost, introduced the scalpel with the left hand into the mouth, and opposing the index of the right hand as a fulcrum on the other side of the tumour, cut towards its middle as close to the parent bone as possible. The knife was then changed to the right hand, and the other half of the tumour cut in like manner. Two of the superior incisor teeth were removed with the mass. No hæmorrhage occurred. Mr. Lynn postponed the excision of the other fungi until the effect of the present operation should be determined. On cutting into the tumour it was found to be cartilaginous in its circumference, but bony in its centre, being a specimen of true exostosis. An astringent lotion was applied; and the bowels were kept open.

Sep. 20. The patient has very much improved since the operation; his speech is more distinct; his appetite and spirits good; and he is well disposed to submit to the removal of the other fungi.

### HOPITAL BEAUJON.

#### POLYPOUS TUMOUR IN THE UPPER PART OF THE PHARYNX.

A ROBUST young man, 17 years of age, was admitted on the 26th of February last, with the following symptoms; the uvula was forcibly pushed forwards and downwards, and on lifting it up by a spatula, a round polyposus tumour of the size of a walnut, of white colour, and apparently of great consistence, appeared behind it; it was loose and pendulous; its pedicle could not be traced, but it seemed to be fixed to the lower portion of the septum ærium; the patient complained of difficulty of breathing, and during sleep was heard to snore very much; his voice was of a nasal kind, the passage of the air through the right nostril was much impeded, that through the left was entirely suspended. On the 27th, M. Blandin applied a ligature according to Desault's method; the change which was observed in the colour of the tumour immediately after the operation, evidently showed that the pedicle was well comprised in the ligature. On the 4th of March (the ligature having been repeatedly tightened during the interval), the polypus was detached and thrown up with a small quantity of blood; the difficulty of breathing, the nasal sound in the voice, etc., immediately disappeared, but the patient complained of much pain in the left ear, from which there was some purulent discharge. A small abscess was discovered to have formed at the posterior part of the pharynx; it was opened,

but the pain in the ear continued, and was for some days even accompanied with so much febrile excitement as to require the use of the lancet. A large abscess formed at the left mastoid process, and being opened on the 20th of March, discharged a very large quantity of purulent matter: the discharge from the ear had evidently been from the same source, for on examination, a communication was found to exist between the abscess and the meatus externus. From this time the patient rapidly recovered, the wound healed up, etc., and towards the middle of April he was discharged well.

### HANDEY v. HENSON.

#### COSTS OF THE TRIAL.

SIR,—After the apparently spirited manner in which some members of the profession seemed at first to notice the signal victory obtained by them through the instrumentality of Mr. Handey, in the case of "*Handey v. Henson*," I did hope that some men of note would have come forward and headed a subscription for the purpose of presenting that gentleman, as a sense of the obligation we owe him, with a piece of plate, but the feeling appears to have lived but for "nine days." Like many others I have been waiting for a leader, none appearing. I have presumed, though but little known, to take the duty on myself.

I know that Mr. Handey has lost, owing to the insolvency of the defendant, the whole of the debt and costs, and that the latter amounted to upwards of seventy pounds. This is a loss that I think the profession is called on to share, and here with forward a sovereign to prove the sincerity of my feeling, trusting others may be induced to follow the example. Should the liberality of the profession get together a subscription beyond the amount of the costs, and I cannot doubt but it will do so, I should suggest that the surplus be laid out in a piece of plate to be presented to Mr. Handey.

Your readiness to stickle for the rights of the general practitioner, renders, I trust, any apology unnecessary for troubling you to receive the subscriptions.

I am Sir, &c.

HENRY EDWARDS.

Oakham, 30th August, 1830.

#### YOUNG BAT CLUB.

A MEETING of some miserable young Bats took place on Tuesday last, at 3 P.M., at the London Hospital. Their movements, like themselves, were very feeble and irregular; we have an eye upon them; it is a pity the poor little creatures have not sense enough to know who are their best friends.

**Experimental Philosophy.**—Although every branch of science has now been extensively investigated, and generally extended to the Medical profession and the public through the medium of lectures, neither the Mechanics nor the Hydrostatics of the animal frame have yet received any distinct degree of notice in this way. The deficiency is now, however, on the point of being supplied by Mr. Barry, whose lectures on Chemistry are delivered at Guy's Hospital. The same gentleman has also introduced a separate lecture on Electro-chemistry and another on Volcanoes; the former intended to familiarize the student with the nature and extent of electrical agency in the production of chemical decomposition;—the latter to elucidate the geological theories of Hutton, Werner, and Cordier, and the electro-chemical theory of Sir H. Davy on the same subject. The lectures will be illustrated by a very extensive apparatus, and the fee is low.

#### MEDICAL TUITION.

**Examinations at the Hall, &c.**—Mr. Knox, No. 26, St. Thomas's Street East, Borough, and No. 1, Well Yard, Little Britain, near St. Bartholomew's Hospital, prepares gentlemen for public examination at the Apothecaries Hall, and other Medical Boards, by a methodical course of instruction and examination. Terms, including assistance in Latin, perpetual, 5*l.* 5*s.*; three months, 3*l.* 3*s.* Complete tuition in Medical Latin. Terms, first quarter, 3*l.* 3*s.*; second and each after, 2*l.* 2*s.*

#### TO CORRESPONDENTS.

COMMUNICATIONS have been received from Dr. Moreton—Mr. Allen—Mr. Mallocks—Mr. Houston—Mr. Green—An Admirer, with the King's Bench Observer—Dr. J.—W.—Edger—Zeta—Mr. W. Dobson—Candidus—Mr. James Waller—Mr. C. Smith—Mr. Wm. Travers Cox—An Apothecary's Apprentice—F. W.—M. H.—Veritas—Mr. Richard Edwards—Mr. J. B. C. Fletcher—An Assistant—J. F. C.—Mr. W. Blennerhasset Fairman—Mr. Dewhurst—An Enemy to Quackery—Mr. George Rees—Mr. J. Curtis—Dr. Theekston.

**L. X. A.** The frequent application of cold water.

The state mentioned by *A Subscriber* is not at all uncommon.

**An Admirer.** Yes, most decidedly; and a chemist can recover in a court of law for medicines actually sold.

**Z.** The brethren have only to assert their rights, and the paltry little creature of brief authority, will sink into nothing before the arm of justice.

The letter of *A Sincere Graingerite* would injure rather than benefit the school.

The pupils who enter to St. Thomas's Hospital, are entitled to see the practice at Guy's. The two hospitals are not at a distance of one hundred yards from each other.

**A Pupil.** The Apothecaries' Act came into operation on the 1st of August, 1815.

**An Apprentice.** It is the duty of a master to conduct himself towards his apprentice in the same way after his indentures are signed, as he did before that period. The law will give relief to the injured party when there is any deviation from that course.

We wish to hear from *Humanitas*.

Private notes will be addressed to several of our Correspondents, and many of the above communications will be inserted next week.

Will a pupil who favoured Mr. — with an account of the meeting that was held at the London Hospital on Tuesday last, favour us with his name and address confidentially. His compliance will be esteemed a favour.

We have yielded to —'s request and inserted the paper, but we cannot publish any others of a similar description. We must say that it has neither point nor argument.

#### BOOKS RECEIVED.

**Practical Observations on Leucorrhœa, Fluor Albus, or "Weakness," with Cases illustrative of a New Mode of Treatment.** By George Jewell, M.R.C.S., &c. London, Wilson, 1830. 8vo. pp. 108.

Two Memoirs on the successful Inhalation of Diluted Chlorine in the early stages of Pulmonary Consumption, &c., with Cases. Translated from the French of M. Gannel, by W. H. Potter, M.R.S. London, Callow and Wilson, 1830. 8vo. pp. 93.

**A Treatise on the Venereal Diseases of the Eye.** By William Lawrence, F.R.S. &c. London, Wilson, 1830. 8vo. pp. 337.

**Traité Pratique sur les Maladies des Yeux, ou Leçons données à l'Infirmerie Ophthalmique de Londres en 1825 et 1826 sur les Yeux.** Par le Docteur W. Lawrence. Traduit de l'Anglais avec des Notes, et suivi d'un précis de l'Anatomie Pathologique de l'Œil. Par le Docteur C. Billard (D'Angers), &c. Paris, Baillière, 1830. 12mo. pp. 499. Translated from THE LANCET.

**Practical Remarks on the Nature and Effects of the Expressed Oil of the Croton tiglium, with Cases illustrative of its Efficacy in the Cure of various Diseases.** By M. J. Short, M.D. London, Longman, 1830. pp. 63.

[1830-31.]

IMPROVED MODE OF OPERATING

IN

LITHOTOMY.

By GEORGE WALKER, M.R.C.S.

ABOUT six years ago I operated for the stone upon a boy two and a half years of age (in the presence of several medical gentlemen of this neighbourhood); upon this occasion I used a beaked knife instead of the gorget (otherwise the operation was conducted after the usual manner); after the incisions were made into the bladder, the forceps were introduced and search made for the stone with them, but not being able to find it, after two or three seconds I withdrew them and introduced my forefinger, when upon curving it and turning it up towards the pubes, I immediately felt the stone at the front and upper part of the bladder, when I introduced the forceps and extracted it; upon examining the stone, a small filament was found attached to it, by which I make no doubt it was suspended from that part of the bladder before described; although, upon this occasion, I was successful, I resolved that when again called upon to perform lithotomy, I would avoid, 1st, the use of the beaked knife, which, after it was introduced into the groove of the staff, I found inconvenient in determining the exact extent of the incision I wished to make; and, secondly, although I had made a moderate-sized opening into the bladder, I found it most advisable to withdraw my finger before I passed the forceps again, rather than run any risk of lacerating the wound by passing them (the *usual* lithotomy forceps) along my finger as I had originally purposed. I therefore, preparatory to two operations which I performed on the 2nd ult., had forceps constructed resembling very much in *size* and *curvature* the common polypus forceps; but in the union of the blades, action of the joint, hollowing out and roughness of the jaws, in every respect the same as the lithotomy forceps. I operated upon these boys, the one being

four the other eight years of age, in the presence of my friend Dr. Warden, surgeon to this dockyard, and several other professional gentlemen of this place in the following manner:—after the usual incisions into the groove of the staff with the scalpel, I continued the incisions with the same instrument under the guidance and guardianship of the fore-finger of my left hand, through the prostate gland, &c., until it (my finger) passed *readily* into the bladder, when I desired the staff to be withdrawn, and my finger came *instantly* into contact with the stone; I then passed the forceps (before described) along my finger, and grasping the stone as soon as they were introduced, I extracted it without any delay; the operation was conducted after this manner in both cases. The boys both rapidly recovered. What I infer then is, that instead of feeling (ineffectually) with the forceps as I did in the first case, and as is usually recommended, I had a very superior advantage by passing my finger through the wound immediately after the knife, and by feeling the stone therewith, was enabled to pass the forceps and grasp it at once, without any delay or difficulty whatever. The forceps I have had made give the advantage by their curvature of being readily passed over the finger upon the stone, let it be found in whatever situation it may, and by their smallness are easily so conveyed without fear of laceration, and are equally as strong as the common forceps.

Sheerness, 1830.

## INSTRUMENT

FOR DIVIDING THE CORNEA IN  
EXTRACTING CATARACTS.

PERMIT me, through the medium of THE LANCET, to publish the plan of a new mechanical contrivance for making the incision in extraction of cataract. The number of instruments which for this purpose have been from time to time devised on the Continent, where the subject receives more at-

tention than it does here, sufficiently proves, that to obviate the difficulties of the ordinary method is yet a desideratum, and render it unnecessary to insist here on the fact, that long practice only can confer the address requisite for guiding the knife with safety, by the ordinary process, through the delicate structure of the eye.

If by the means I am about to propose, security and facility be attainable without an experience injurious in its first essays, surgery will be much indebted to mechanics, and an operation, now confined to a few who have gone through a tedious probation, will be placed within the reach of any one who gives but ordinary attention to the subject.

#### *Description of the Instrument.*

Fig. 1, front view. Fig. 2, back view.

*A*, the blade, acting upon a centre at *B*, and impelled by a spring. *C*, a perforated plate, with bevelled edge, through which the cornea is to project. *D* (fig. 2), another perforated plate, with a larger aperture, and edge more bevelled, which rests upon the globe of the eye. *E*, a screw, by turning which, the upper plate, together with the blade, is raised or depressed, as the varying convexity of the cornea may require; it is, however, seldom found necessary to alter the elevation of the plate.

In using the instrument, the blade is first to be set up by pressing it from the position shown by the dotted lines to its present position, *A*. The operator then opening the lids with the left hand, places the instrument on the eye, having the forefinger of the right hand on the button, and taking care that the edge of the cornea corresponds with the circumference of the hole in the upper plate; or, in other words, that the surface of the plate be brought to a level with the plane of the iris: this is accurately performed by means of the screw. The instrument being thus adjusted, it is only necessary to keep it close upon the eye, when, by pressing on the button *G*, fig. 2, with the forefinger, the blade is liberated, and the spring carries the point through the cornea, making a section of half its base. This being done, the instrument should be removed, and extraction proceeded with in the usual manner. If, however, after the introduction of the capsule needle, it be necessary in order to protrude the lens, to make slight pressure on the eye, it cannot be more equably and safely performed, than by the reapplication of the instrument.

The advantages of this method of operating, may be briefly enumerated as follows: The use of the instrument being of easy acquirement, and capable of steady and accurate adjustment, the important advantage of an incision of proper size is ensured,

the want of which is not infrequently a cause of failure. The smoothness of the incision is of consequence in facilitating union and preventing the cicatrix being, as sometimes happens, a great bar to vision. The rapidity with which the blade passes through the anterior chamber, does not allow time for the aqueous humour to escape before the incision is completed, and thus the most frequent cause of the iris being wounded is avoided; the quickness of the motion also, by causing little or no pain, prevents the mischief which sometimes arises from the swerving of the patient. Another advantage is, that while the eye is rendered immovable, the distortion produced by the ordinary method of steadying with the finger is avoided, and the chance of giving exit to the vitreous humour, is thus diminished.

In conclusion I have only to add a hope, that if the instrument be adequate to the end proposed, it may not be sacrificed to a prejudice against mechanical contrivances, which, because they render skill unnecessary, are thought unworthy of the skilful. If, on the contrary, there be solid objections to its employment, I shall regret its failure, only because there will still remain a difficulty unobviated, and a source of evil to the afflicted unremoved. I remain, Sir,

Your obedient humble servant,

THOS. R. WILLIAMS.

17, Norfolk Street, Sept. 1830.

#### DISEASE OF THE VALVES OF THE RIGHT SIDE OF THE HEART.

*By WILLIAM THOMPSON, Surgeon.*

If the editor should consider the following case worthy a column in *THE LANCET*, he will oblige me by its insertion. It appears to me important, as illustrating a rare occurrence in pathology, viz. disease of the valves of the right side of the heart, a disease which, I believe, many experienced morbid anatomists have not had an opportunity of observing.

The lady was forty-eight years of age; the principal symptoms which were observed, connected with the disease of the heart were, orthopnoea, increased on the least exertion, occasional attacks of palpitation and faintness; the heart's action more extended than natural, but the impulse not increased; the pulse feeble and irregular. The patient gradually sank, and died on the 16th of last month.

On examining the chest, about two pints of amber-coloured fluid were found in the right cavity, but none in the left. The

Fig. I

Fig. II.

right lung was almost universally hepatised, some parts presenting the appearance of what is called pulmonary apoplexy. It may be right to mention, that the patient had hæmoptysis during the last few days of her existence. The left lung was perfectly healthy; a small quantity of fluid was found in the pericardium; the right auricle was of about double its natural size; the right ventricle also was dilated and somewhat thickened; *the tricuspid valves were thickened and cartilaginous throughout*, and the foramen of communication between the right auricle and ventricle, would admit of the introduction of four fingers. The left auricle and ventricle were healthy, but the mitral valves were thickened, and the foramen of communication would admit with difficulty a full-sized thumb. The semilunar valves of the pulmonary artery and aorta, were perfectly healthy, as likewise was the aorta.

The patient was attended by Dr. Blundell, who was also present, and assisted at, the post-mortem examination.

Lambeth, Oct. 2nd, 1830.

#### AMPUTATION OF THE LEG AT THE KNEE-JOINT.

At the sitting of the Académie des Sciences on the 15th of September, M. Velpeau, of the Hôpital St. Antoine, read a paper on the above operation, which, according to him, is not so dangerous as is generally believed, and ought even to be preferred to ordinary amputation, where the joint is healthy. He has himself performed it twice with complete success, once in January, 1830, on a young man affected with necrosis of the tibia, part of which it was M. Velpeau's intention to remove, when he found, after having made a transverse incision, that the bone was throughout diseased, so that it was necessary either to perform the amputation of the thigh, or the exarticulation of the leg; he preferred the latter, as, in fact, a part of it was already performed by the transverse incision. The operation did not afford any-thing of interest; the wound speedily healed, and the patient was quite well after eight weeks. The second case was that of a robust man, 29 years of age, with fracture of the left leg: when he was brought into the hospital, twenty-four hours after the accident, considerable hæmorrhage had taken place, and almost the whole of the limb was covered with ecchymosis; the fracture appeared, however, simple, and there was but a small wound at the inner angle, and scarcely any swelling. The limb was carefully dressed, and a favourable result of the case was anticipated, when, on the following night, the patient was suddenly seized with furious

delirium, the cause of which could not be ascertained until the fifth day, when it was discovered that mortification began to take place, and three incisions having been made over the fracture, the tibia was found to be minutely fractured, and its fragments surrounded by a gelatinous mass of very offensive smell. Profuse suppuration of an unhealthy kind ensued, accompanied by excruciating pain and hectic fever, so that the removal of the limb did not admit of any longer delay. The success of the above case determined M. Velpeau to perform the exarticulation of the leg at the knee-joint, as amputation below it was inadmissible. The operation took place on the 4th of June, and the patient was perfectly cured on the sixtieth day. The third case which had come under M. Velpeau's observation, was that of a young man whom he happened to examine at the Bureau Central, and who in his twelfth year had undergone the operation at the Hôpital des Enfants, on account of gangrene. From these instances, and others related by medical writers, M. Velpeau concludes, that exarticulation of the leg ought not to be entirely excluded from the index of surgical operations, as it has hitherto been done by most modern writers on surgery.

#### SINGULAR CASE OF MONSTROSITY.

At the sitting of the Académie Royale de Médecine on the 2nd of March, M. Olivier, of Angers, reported the following case of congenital monstrosity:—The appearance of the eye-lids was very striking, they were closed, and instead of being prominent, were flattened, and their edges adherent. They were accordingly divided, but when M. Olivier raised the eyelids to examine the eyes, he was astonished to find, that in their stead there was only a mass of adipose cellular tissue, with some reddish fibres. The child moves the eyelids, and there is a slight discharge of whitish fluid from between them; it is in other respects well formed, and had at the time of the report attained its fifth month.

On the 30th of March, M. Luzardi communicated to the Academy the description of two cases similar to that observed by M. Olivier. In one of them both eyes were wanting, and their places were not even filled with cellular tissue: the eyelids were not adherent. In the other case the child had been born with closed eyelids, and was two months old when the adhesions were divided. The left eye was completely wanting, the right not deformed, but very small, atrophic, and affected with membranous cataract.—*Bullet. d. Sc. Med.*

REMOVAL OF A TUMOUR ON THE TONGUE  
BY THE LIGATURE.

A peasant girl, in the neighbourhood of Wilna, had, from her birth, a small bluish tumour on the right edge of the tongue near its root. It was of the size of a bean, but gradually became larger, and at her seventh year had attained the size of a plum; from this time it remained stationary till her fourteenth year, when it suddenly became much larger and very painful, so as almost to impede swallowing and speaking. On the first appearance of the menses, its growth seemed again to be arrested, and the pain in it was considerably relieved by a profuse hæmorrhage from a slight laceration of the tumour by the teeth in eating. In 1828, when the girl had attained her sixteenth year, the growth of the tumour increased so rapidly, that she was in danger of being suffocated whenever she attempted to lie down. At this period she first applied to Professor Galengowsky, of Wilna; the tumour began at about eight lines from the tip of the tongue, and extended as far as the root; it filled almost the whole of the mouth, leaving only an interval of three lines to the roof of the palate; it was flattened anteriorly; behind, its form was entirely adapted to the cavity of the mouth. It was of blue colour, soft, and somewhat elastic, but without perceptible pulsation; mastication and swallowing were almost impossible; articulation was less impeded, though she spoke like a person who has something in his mouth. Professor Galengowsky decided upon extirpating the tumour, and with that intention passed a thread through the posterior part of the tongue, in order to fix it in the necessary position; the puncture caused, however, such a violent hæmorrhage, as to induce the operator to give up all hopes of removing the tumour by the knife, and he accordingly resolved to apply a ligature. A strong double silk thread was passed through the healthy part of the tongue from one side to the other; the ligatures were then separated, and the tumour comprised between them; the tongue immediately became of a livid colour; the patient complained of a violent shooting pain in the pharynx, lower jaw, and the right temple; a slight hæmorrhage ensued after the operation; when it had ceased, and the tumour was again examined, it was found that a small portion of it had not been comprised in the ligature, and it was accordingly necessary to apply a third. After the operation the tumour was covered with ice, and the cheeks were kept cool with an evaporating lotion. After a few hours the pain subsided, the tumour became larger, and a new hæmorrhage supervened; the ligatures were accordingly tied more firmly.

On the second day, the right side of the face became violently inflamed, so as to require the repeated application of leeches, but the tumour of the tongue was quite insensible, and being much less tense than on the previous day the ligatures were again drawn more tight. This was repeated every other day; on the eighth the tumour spontaneously came off in a state of putrefaction. The wound was repeatedly washed with solution of the chloruret of lime, which had such a good effect that it soon became of a healthy appearance, and was completely cicatrised within three weeks. It was, however, in June, found necessary to apply the actual cautery to a small portion of the tumour, which had not been comprised in the ligature. At the beginning of July, she was quite well; the only trace which the tumour had left was a small depression on the right edge of the tongue; the patient had however, some difficulty in moving it, and was unable to pronounce *h, l, t, g,* and *v*.

On examination of the tumour, it was found to contain a nucleus formed by concentric strata of horny structure, the centre of which was occupied by a drop of a limpid water-likeliquid.—*Graefe u. Walther Jour. d. Ch. u. Augenheilk.*

## DEATH OF MR. HUSKISSON.

To the Editor of THE LANCET.

SIR,—The newspapers have already, no doubt, made you acquainted with most, if not all, of the particulars connected with the accident and death of Mr. Huskisson. Many are now speculating upon the surgical treatment of this case, and the general opinion of the faculty here, so far as I have been able to ascertain it, is, that it was unscientific, inefficient, and imbecile. Indeed there is some foundation for believing, that had amputation of the limb been early undertaken, the life of this great statesman might have been saved. A writer in *The North Briton* of Wednesday last, thinks that a navy surgeon, had he been on the field at the time, would not have suffered the opportunity of operating to escape, and this was the man most likely, he concludes, to have effected what was omitted, and what, in all probability, would have ensured the safety of the patient. Another writer, in *The Liverpool Albion* of this day, exclaims, "Why was not the operation of amputation instantly performed?" He sarcastically alludes to the invention and skill of the "Great Oldfield Lane Doctor;" in contradistinction, and by way of comparison, with the men and measures concerned

in this affair. Many of the remarks of this anonymous writer, who is evidently a medical man, are feasible and conclusive, but he indulges in a vein of satire and sportiveness which might bespeak, according to the estimation of some, no suitable feeling of the heart, while they do not heighten the interest among those who may read with a view to obtain information. An army, or a navy surgeon, might have saved the life of Mr. Huskisson, and so might any other surgeon, whose head and hands knew how and when to do their duty. However, I am decidedly of opinion, that had prompt and energetic measures been undertaken, the patient would have, in a great degree, been spared the torture of those spasms and twittings of the muscles and tendons, which are reported to have been so severe, and which proceeded from the loss of blood, and not, as has been stated, from the torn and mangled state of the nerves and other soft parts. Amputation, therefore, might have rescued the victim.

Mr. Huskisson bled profusely for a length of time, and until his clothes and all about him were literally drenched in blood; and although the *great blood-vessels of the limb were entirely denuded and exposed*, I am informed no means beyond placing a handkerchief round the leg were taken to stop the flow of blood; surely the hæmorrhage might have been instantly arrested by securing those vessels; or, if this could not have been done (a circumstance not very likely), I should have immediately decided, as the only alternative left, upon removing the extremity with the knife; this would have been following the directions and practice of the most eminent surgeons of the day, and if it had failed of success, the expediency and exigencies of the case justifying the measure, there could be no blame attached to any party.

Nothing is more easy than to get up whys and wherefores, and to call in question the theory and practice of any man; and of all the arts and sciences, the art and science of healing, as they have been taught and followed in every age, have been, and are, perhaps, the least famed for any thing fixed and unalterable in their economy. But then this does not arise from the constitution of medicine, which in itself maintains facts and laws, as effective and unchangeable, as are to be found in any other business or pursuit of life. After all, therefore, it might be urged in defence of the mode of procedure by the medical men in attendance upon this case, that they had the advantage of seeing it, and, consequently, it may reasonably be supposed they were in a situation the best qualified to judge and act correctly.

Notwithstanding, it is my conviction, as I have stated elsewhere, that those same

medical men might, and *should*, have done more in this affair than they did.

Your well-wisher,  
And very obedient servant,

THOS. WEATHERILL, M.D.  
Liverpool, Sept. 27, 1830.

P.S. Might not a medical coroner have been of use at the inquest upon the body of Mr. Huskisson? The jury brought in a verdict of "Accidental death."

Your late struggle for the vacant office of Coroner for Middlesex demands my most unfeigned admiration and applause, and in this I am joined by the voice of a large body of the profession in Liverpool. Like Othello, the lawyers may now exclaim,—That their occupation, in this respect, is gone.

## SOCIETY OF "GENERAL PRACTITIONERS."

*To the "General Practitioners" of the  
United Kingdom.*

BROTHER PRACTITIONERS,—It is a satisfaction to me, and it ought to be a satisfaction to you, that we have a channel always open for disseminating our communications extensively among the members of the profession; and I gladly avail myself of it, by addressing this letter to you, in the certain expectation of its meeting your eyes in the pages of THE LANCET. Every general practitioner who has read that journal from its commencement, as I have done, ought to know that it is his proved friend, the advocate of his rights, the supporter of his reputation, the champion of his battles; and he who does not feel this, is either an ignorant blockhead, or an ungrateful knave. I have been, sometimes, rebuked for my adherence to this publication, on account of its "naughtiness;" I inquire how it has offended, and I am told that it calls "nicknames" and abuses persons unceremoniously! I must tell these squeamish friends who are so dainty in picking up truth, that a nickname must be appropriate to the character before it will attach to the person; and, if applicable, the individual has but to blame nature or fortune for the consequences. To call the Duke of Wellington a "little cock-sparrow," would be senseless, while another man might be cut down by the sarcasm to the proper measure of his insignificance. Our doughty Editor knows the power of ridicule, and wisely prefers its application to those persons upon whom reason and argument would be thrown away. THE LANCET offends by the *plainness* of its speech, does it? What! ye silver-tongued hypocrites, who frost poison with sugar, and

robe your malignity in the silken drapery of ambiguous courtesy, does science hold its court in a language framed to conceal the thoughts; or does honesty teach our manners to "smile, and smile, and smile, and murder while they smile?" THE LANCET attacks fiercely, but it bites without venom.

Brother Practitioners, the subject that I have to mention to you is the new association denominated the "Metropolitan Society of General Practitioners." I have read over its address with great attention, and I confess that its views and promises merit deeply our regard. I am desirous of knowing what the profession thinks of the scheme, and how it is inclined towards the undertaking. After making the above remarks upon the conduct of THE LANCET, it will be inferred that the Editor's strictures upon the address, published last week, will dispose me favourably to the Society; I admit that it did so influence me, for after I had read the articles I went to the Society's chambers for further particulars. The porter only, was in attendance, from whom I could learn but little; I could not even obtain a copy of the laws, every one of which, the man informed me, had been issued; this, I will take leave to remind the Committee, is bad management. The rooms seem convenient and comfortable for sipping coffee, and social chat, but are certainly not sufficiently commodious for large meetings. I am given to understand that the address is the production of one of the officers of the Society, and I, therefore, for your information and my own, request of this gentleman some explanations that I think we all require.\*

1. Who are the gentlemen at the head of affairs?

2. Is it intended to legalise the Society by procuring a charter?

3. What plan is formed for prosecuting the views held out in the address?

4. Are the places of trust and office open to the whole body of the Society?

5. Are the acts of the Committee or Council cognizable to the members generally, and is that body responsible to, and elected by, the Society at large?

6. Is the Society to have a veto in the construction of laws, and in the application of its funds?

7. In the event of the formation of a complete club-house system, will the whole of the members be called on to support it by additional subscriptions?

These are questions, Brother Practitioners, which it is necessary should be

\* Mr. Scott of Regent Street, is, we understand, the author of that eloquent and comprehensive paper. This gentleman has evinced so much liberality and spirit in all the matters connected with the Society, that he will, we are persuaded, feel satisfaction in replying fully to the whole of the questions of our intelligent correspondent.—ED. L.

answered; if the replies be satisfactory, I think it is incumbent on us to give our support to the plan, and I shall immediately propose to become a member of the Society. But before I close my letter, allow me to intreat the Committee to give attention to any suggestions offered by our friend THE LANCET, and to be assured that whatever opinions proceed from that quarter, arise from a knowledge of the wants and wishes of the profession, and are prompted by a sincere desire to promote the prosperity and respectability of the general practitioner.

I subscribe myself, Gentlemen,

Your friend and servant,

A SURGEON,

London, October 4, 1850.

I am glad to observe symptoms of retreating courtesy between Dr. Johnson and Mr. Wakley; an adjustment of all differences would do credit to their good feelings, and benefit the cause of those in whose service they are engaged.

---

"PASSAGES FROM THE DIARY OF A LATE PHYSICIAN."

---

*Note to the Editor of Blackwood.*

"SIR CHRISTOPHER,—A letter under the title of "Blackwood's Magazine v. the Secrets of the Medical Profession," appeared in THE LANCET of the 28th August last—"the most influential and popular organ," it says, "the profession possesses,"—a paragraph from which, I beg to extract, and call the attention of your numerous readers to it. I do this in justice to myself; because in the event of my name, insignificant perhaps as it is, happening to be disclosed, the said letter is calculated to work me much prejudice with my professional brethren, and also with the public in general; for I need not tell you, Sir Christopher, of the extensive and miscellaneous circulation of the publication alluded to. After some complimentary remarks, the writer proceeds—

"But I enter my protest, as a physician in some little practice, against the custom of disclosing to the public the sacred secrets which are communicated to us in perfect confidence by our patients, and ought to be preserved inviolable. The Editor of Blackwood happily enough says, 'What periodical has sunk a shaft into this rich mine of incident and sentiment?' True: the value has been, and is yet, I hope, to be proved, in the honour of our profession, and the determination of its members to merit the confidence of their patients, by continuing, in the language of Junius, 'the sole depository of their secrets, which shall perish with

them.' If the writer of the paper in question, or the Editor of Blackwood, should see this letter, they are *implored* to consider its purport; and thus prevent the public from viewing their medical attendants with *dis-trust*, and withholding those confidential disclosures which are essential to the due performance of our professional duties. The very persons who would read such a series of articles as the 'Passages from the Diary of a late Physician' promise to be, with intense interest, would be the first to act on the principle I have mentioned.'

"If I were not credibly assured, Sir Christopher, that this letter is the production of a distinguished member of the profession, I should have felt inclined to compress my commentary on it into one emphatic little word—*humbug*! As it is, however, I beg to ask the writer who is so ready at starting the grave charge of a breach of professional confidence, what I do more, in publishing in your Magazine these papers of my late friend, with the most scrupulous concealment of every thing which could possibly lead to undue disclosures, than is constantly done in the pages of *THE LANCET* itself, as well as all the other professional journals, text-books, and treatises, which almost invariably append *real initials*, [I appeal to every medical man whether such is not the fact] and other *indicia*, to the most painful, and in many instances, revolting and offensive details?" — *Blackwood's Magazine*, Oct. 1830.

---

MR. LYNN AND MR. ELMORE.

To the Editor of THE LANCET.

"When thieves fall out, somebody comes to his own."—*Proverbs*.

SIR,—Proverbs are not the most elegant vehicles of wisdom, but we ought not on that account to reject them; by this mode Solomon and Sancho Panza gave us more practical truths, than we have derived from any other source since the deluge. Deprecating your objections to these plebeian morsels of morality, let us see how far my motto will apply to the present question.

For the Council of the College of Surgeons I have the most profound contempt; for their principles and proceedings I have an abhorrence even to loathing; therefore I shall not be suspected of the infamy of attempting their defence or justification. Yet cannot help thinking that the disappointed candidates for seats in the council, are not entitled to the sympathy or support of their brethren the members. On what grounds do the rejected gentlemen found their

claims to the *honour* to which they aspire, and to what uses would they apply the power when obtained? They demanded to become councillors on the ground that they were "pure surgeons;" and doubtless, as councillors would do nothing to expose the fallacy of their claims to distinction, they would do nothing to procure for the members at large equality of honours and emoluments; they would not vote for the admission of those members who are general practitioners; they would not, on the exclusion of one of this much-injured body, resign their seats, rather than herd with men whose public acts are a reproach. Under these circumstances, I cannot allow that the complainants deserve the countenance and assistance of their fellow members.

From the "pure surgeons" the councillors are selected; from the council are elected the examiners, and from the examiners is chosen the president; the claims of the disappointed are founded on corruption, and they ought not to be assisted by the independent. The point at issue reminds me of Sir Robert Walpole's definition of a "certain kind of patriot." This *patriotic* minister boasted he could make forty patriots in a night; his recipe was simple, and must be known to the council of the Royal College, "Refuse a man a favour, and up starts a patriot."

Your faithful servant,

WM. AUGUSTUS WALFORD.

Oct. 2nd, 1830.

---

DRS. GORDON SMITH, RYAN, AND  
A. THOMSON.

Note to Dr. Ryan.

DR. GORDON SMITH presents his compliments to Dr. Ryan, and desires to inform him that he has seen the article in the *Medical and Surgical Journal* for this month, in reply to Dr. Smith's defence of Dr. Thomson's medico-legal document. It is Dr. Smith's design to insert a few words on the subject in the forthcoming number of *THE LANCET*; but in consequence of the unauthorised use which Dr. Ryan has made of Dr. Smith's *private* communications, the acquaintance between them necessarily terminates.

Oct. 1, 1830.

To the Editor of THE LANCET.

Having forwarded the above to you, Mr. Editor, I may as well take public leave of Dr. Ryan, by adding the following explicit statements. Dr. Ryan certainly did join me in an application to the Court of Examiners at Apothecaries' Hall, on the sub-

ject of enforcing the study of forensic medicine; but the strictures on Thomson's report had not made their appearance when I admitted Dr. Ryan to this co-operation. I have in my possession, however, satisfactory evidence that Dr. Ryan's aid was neither required nor effective in the accomplishment of the important object. I should nevertheless have left him in possession of all the merit he might have supposed himself entitled to, had he not gone the length of saying, that he suggested great alterations in the letter (which were adopted by me of course). Now as that letter was neither private nor confidential, any person who may think an inspection both of the letter as it was sent, and of Dr. Ryan's *rejected* emendations, worth the trouble, may see copies of the same, as they have existed since the 14th of August last.

J. GORDON SMITH.

P.S. I have just looked at the copies in question, and find that the Doctor's emendations occupy nearly three columns in the MS. in his own hand-writing, *the whole of which* appears to be dashed out; and I can assure you, that with the exception of very few words indeed, which I adopted from Dr. Ryan's *version*, merely because I had made a promise to that effect, the whole letter is my unassisted composition, as the idea of transmitting it was my own original conception.

INQUEST AT THE WESTMINSTER HOSPITAL.

[We publish the following letter precisely as it reached us.—ED. L.]

To the Editor of THE LANCET.

SIR,—Accidentally glancing over one of your interesting numbers (No. 367) I cast my eye on the proceedings of an inquest which contains very unjust strictures on my professional character. Not intending to animadvert on the opprobrious epithets used by an anonymous writer in THE LANCET I shall only express my feelings as a medical man concerning the erroneously imputed charge of accompanying and co-operating with a Mr. Mills pretender to medical science. Far is it from my intention to notice and exclaim against the ungentlemanly calumnies *coined* by some humorous correspondent and issued to a credulous public thro' the keen and almost super-intelligent media of some periodicals!—but my solitary wish is to state (with manly candour and open sincerity as a sincere well-wisher of the medical profession) that so far from associating with the untutored imps of empericism or patronizing the ragged rabble of illiterate pretenders, I shall

always consider it an imperative duty to destroy the fatal deacon of imposition and proclaim open warfare against the pseudo-illustrious descendants of quacking ancestors. In THE LANCET it is affirmed that I am shielded by the ægis of my patron's surgical reputation; but I can assure the generous reader that my *professional* ægis is in actual dissection in the proper rendezvous for surgical skill my *moral* ægis is the 'mens conscia recti' which will uphold every advocate for truth and scientific 'induction' altho at the same time I am proud of the splendour which my able friend Mr. Lynn's professional acquirements spreads around the very humble name of

Yours respectfully  
WILLM. ORD.  
Broad Way  
Westminster.

Sept. 29, 1830.

NON-MEDICAL CORONER'S INQUEST AT  
PORTSEA.

To the Editor of THE LANCET.

SIR,—Observing in the 369th No. of the LANCET, a letter signed "Philander," containing a statement relative to the question of non-medical coroners, which happens to be very wide from the *truth*, I forward you the following, convinced that *truth* alone can benefit any question. The discovery of Winney being murdered, chiefly arose from the suspicions of the surgeon who gave evidence on the first inquest, and led to a second inquest. It was twenty-four hours after this discovery by the first surgeon and the others present, that the borough Coroner, by direction of Ed. Carter, Esq., mayor, and the surgeon named in your Correspondent's letter, had the opportunity of having a view of what was already discovered. One day before this, the first surgeon and the others present had found the head fractured, and more extensive injury in the throat than had been at first suspected; but the vertebrae of the neck were *not* partially severed, as has been stated. It is very wide from the truth, that a *small* effusion of blood proved that life was almost destroyed by the blow on the head; as there was an *immense* pool of blood found by the body, and the clothes also were bathed in blood. Your Correspondent has not been candid enough (probably from his ignorance of many material facts) to state, that before any surgeon saw the body, it was conveyed a distance of near a mile by water; in being jostled about, the blood, yet fluid, of course stained many parts it would not otherwise

have touched, and thus misled surgeon, coroner, and jury.

The paragraph "of the convicts' reasoning, that the man had not committed suicide, &c." has its foundation only in your correspondent's account: such never was the case, as a laboured investigation of four days could with the greatest difficulty lead to detection; and this I do not hesitate to say would never have been known, had it not been for the medical evidence, as the testimony of the convicts went no further than to establish *suicide*, not *murder*. Of the other two cases I have no knowledge except from report,

I remain your obedient servant,

VERITAS.

Portsea, Sept. 27th, 1830.

### CORONER'S INQUEST AT HAMPTON.

FRANCES CLARK, the wife of a labouring man residing in the parish of Hampton Wick, was taken in labour of her sixth child on Saturday the 25th of July last. Ann Ellam was in the house a few hours after the pains first came on, and shortly after Mrs. Elliott, a laundress, and Mrs. Chilman, a midwife, were sent for. The labour being tedious, and the midwife anxious, a surgeon of Teddington was, after the lapse of some time, applied to, and on his declining to attend, Mr. Bowen, a surgeon of Hampton, was called in. A long period having elapsed from the commencement of the labour, and but little progress having been made, the husband and attendants wished Mr. Bowen to obtain further advice. The presence of another medical gentleman, however, was not to be had without a request by "note" from the surgeon himself, and this note Mr. Bowen refused to give. Several hours after this suggestion, the patient died undelivered, both arms of the fœtus having been first removed. After the usual period the woman was buried, but rumours were spread highly unfavourable to the treatment adopted by Mr. Bowen, and a statement that a boot-hook had been used by that gentleman during the attempts at delivery, increased the feelings of prejudice. Some inquiry was then entered into by the parish officers, but this only went to ascertain how far the surgeon of Teddington had been culpable in declining to attend; and as it appeared that he was not in any way bound to comply with the request of the messenger, nothing further was done to elucidate the truth, until the proceedings were adopted in order to obtain the present inquest, the warrant for which was not issued, we understood, until after the

coroner had been threatened to be served with a *mandamus* by Mr. Guy, who acted as the solicitor for the husband of the deceased. A jury, of which Mr. Everett the banker was foreman, accordingly assembled on Saturday morning last, October 2d, at the Bell Inn, Hampton. Great interest was excited by the proceeding, and between those who attended from curiosity, and those who were summoned as witnesses, almost every medical gentleman residing in the neighbourhood was present. Mr. Wakley was also in attendance at the special request of some parties who were deeply interested in the inquiry. Objections were made to some of the jurymen by Mr. Guy, but these were over-ruled by the coroner.

After the jury had been sworn, some dread of examining a body which had been so long interred, was expressed by them, and Mr. Everett, the foreman, contended that there was no necessity for opening the coffin, and that the remains must be in such a state of putrefaction, that it would be impossible to collect any satisfactory evidence from them, the body having been buried nearly ten weeks. After some remark from the coroner, which we could not hear, Mr. Wakley said, that it surely was not necessary that he should remind Mr. Stirling and the jury, that it could be no inquest at all if they omitted to take a view of the body. The coroner and jury accordingly proceeded to the church-yard, and the body was taken from the coffin: most of the jurymen speedily removed from the scene. The medical men gathered round, and at the suggestion of Mr. Wakley the body was opened. This operation was kindly performed by Mr. Mitchell, of Richmond. The progress of decay had not been great, and the integuments of the fœtus, to the apparent astonishment of all persons present, were natural in colour and firm in texture. Upon opening the abdomen, the anterior part of the uterus appeared sound. On cutting through this viscus, and completely turning aside the uterus, the fœtus was at once exposed to view. The body of the fœtus was lying across the pelvis, the right side of the face resting upon the brim of the pelvis, the chin being nearly opposite the symphysis pubis, the head doubled considerably upon the chest; the thorax much distorted by compression, and considerably sunk into the pelvis. On slightly turning the head, there were seen some jagged portions of integument and broken muscular fibres, which proved to be the remains of the left shoulder-joint, the arm having been removed. The fœtus was now raised, and it was found that the remains of the right shoulder-joint were low down in the vagina, a small strip of integument even protruding at the os externum. The entire right upper extremity, together

with the scapula on that side, had been removed. Immediately opposite to the axilla on the right side, the vertebræ were separated and fractured, the ribs broken, and a considerable aperture was made into the right cavity of the thorax, where some instrument, probably the boot-hook, appeared to have freely passed. The spine appeared to have been pulled with considerable force, the apex of the angle thus produced, presenting to the os externum. Upon looking at the head, the cranium did not appear to be at all compressed, but was of the natural form and size. On carefully examining the scalp, an aperture about the size, as stated by Mr. Jewell, of the tip of the middle-finger, was observed upon the occiput, and there was a fracture of the posterior inferior angle of the right parietal bone, which was here broken into three or four portions. The scalp over this part was darker than in other situations, but there was no wound in it; indeed, the broken bones maintained their natural position, and there was no communication between the fracture and the small opening in the scalp found upon the occiput, the cellular membrane between the fracture and aperture being found uninjured. The bone immediately under the hole in the scalp was perfectly sound, and thus it was evident, from a careful external examination, that the head of the fœtus had not been opened in the attempts to procure delivery, although it was alleged that craniotomy had been performed. As the external examination had established it as a fact beyond all dispute, that the brain had not been removed by means of any surgical operation, much surprise was depicted on the countenances of many of the medical gentlemen, when, upon separating the bones of the skull, the cranium was found to be not half occupied by a thickish light-grey fluid matter, of about the consistence of cream. It was probably unknown to many of the gentlemen present, or it had entirely escaped their recollection at the moment, that the fœtus had been dead for very nearly ten weeks. The contents of the cranium, then, were in perfect conformity with the appearances which are known to present themselves after the lapse of so long a time. The soft parts of the mother did not appear to have been injured at all by instruments.

Amongst the gentlemen who attended the inquest, Dr. Hunter of Richmond, Mr. Jewell of Sackville Street, and Mr. Neville, were stated to have been invited on the part of Mr. Bowen. Mr. Bowen was not himself present at first, but at the request of the coroner he was sent for to the jury-room. Sir Andrew Halliday had also been summoned, but he stated that he did not know why. Previous to viewing the body, a protest was made by Mr. Jackson, solicitor

for the parish, against the inquisition, on the ground that it was invidious, unnecessary, unjustifiable, and expressly against the wish of the curate and churchwardens. Many of the friends of Mr. Bowen also warmly deprecated the inquiry. The first witness called was

ANN ELLAM, a widow residing on Hampton Common, who occasionally assisted Frances Clark as a washerwoman, and was with her on Saturday the 25th of July last. On that day Mrs. Clark, who was then in good health, first felt the pains of labour. Mrs. Elliott was there soon after, and on Sunday evening at six o'clock, witness went for a midwife, Sarah Chilman, on whose arrival Mrs. Clark retired to bed, where she remained crying and screaming the whole night. Towards morning she, witness, inquired of the midwife if the labour advanced at all. The reply was, that it did not, and Mrs. Chilman added that if the delivery did not take place before ten o'clock on Monday morning she must have some assistance. Mrs. Clark accordingly wished for the attendance of a surgeon from Teddington, for whom witness immediately went. She told him that Mrs. Clark had been in labour all Sunday night, and that the case was now so difficult that the midwife and friends wished him to visit her, but he refused to do so. He said they owed him five pounds already, and might go to Hampton for a doctor. The witness accordingly returned, and to save Frances Clark's feelings told her that the surgeon was not at home. She subsequently went to Hampton for Mr. Bowen. Mr. Bowen promised to attend, and came at half-past ten on Monday morning. Mrs. Elliott went into the room with him. He remained there half an hour. On leaving he stated to witness that "he had put every thing fair and straight for the midwife, in case any thing occurred." He came again at nine in the evening (Mrs. Elliott was not then present), and inquired of witness for the instruments he had left in the morning, and of these he made use. He inquired for Mrs. Elliott, saying, however, that Frances Clark was doing very well at present; that he should want her by and by and would then send for her, giving them every hope that the labour was proceeding properly. At ten that evening Mrs. Elliott came, and continued with Mrs. Clark until her death, which took place at about a quarter past ten on the following Tuesday morning in witness's presence. Mr. Bowen, while with the deceased, requested to have a boot-hook lent to him, which implement was procured at a neighbour's. On further examination of this witness, the following testimony was given. Frances Clark said, between three and four o'clock on Monday morning, that she believed her child was

dead. Fearing that all was not going on right, the deceased was asked by the witness, in the presence of Mr. Bowen, if she would not like to have some other medical gentleman. The deceased replied urgently in the affirmative. Mr. Bowen said nothing to this, but on being referred to for his consent replied that the labour was going on perfectly right, and he did not seem to think any other advice necessary. The husband also made the same inquiry, and Mr. Bowen said the labour would soon be over. The wish of the deceased was, however, complied with by the friends, and Mr. George Taylor, surgeon, of Kingston, was sent for. While the messenger was gone Mr. Bowen had recourse to his instruments, and these he "used with very great force; the perspiration poured off him; he put his back against the wall, and his feet against the bed, and pulled with a napkin with all his force." (It was observed by a medical gentleman in the inquest-room, that an accoucheur could hardly attend a difficult labour in the month of July without perspiring freely.) "Something then gave way, the sound was like a bit of stick breaking and the witness saw a child's arm pulled off. Mr. Bowen gave a nod to Mrs. Elliott, produced the arm from under the bed-clothes, and laid it on the floor." After this the messenger who went for Mr. Taylor returned, and stated that Mr. Taylor declined coming unless Mr. Bowen sent a note requesting his attendance. This request Mr. Bowen refused to make. He said that Mr. Taylor might come if he liked, but when he, Mr. Bowen, wanted skill, he would send for it. If they could find any one who could do more for Mrs. Clark than himself, they might send for that person, but he would give no note to any-body. Witness had had ten children, but never before knew of so difficult a labour. Frances Clark had had several very fine children. Witness did not see more than one arm removed. To a question,—Did Mr. Bowen show any disinclination to attend at the first?—witness replied, No, none at all.

*Examined by Mr. Jewell.* You said Mrs. Clark cried and screamed very much; is not that very common with women in labour? Yes; but I never heard so much.—Did Mr. Bowen say why he used a boot-hook? No.—Are you aware that an instrument very like a boot-hook is often used in midwifery, and that force is often necessary? Witness did not know. Some gentlemen present here adverted, in palliation, to the facts of the deceased having said that the fetus was a dead one, that a great many hours had elapsed before Mr. Bowen's presence was procured; that the statements of Mr. Bowen that Mrs. Clark was doing well, were justified by the practice of always

encouraging parturient women; that Mrs. Clark had had a fall a few days previous (no injury was complained of from this); and, finally, that it was not imperative on Mr. Bowen to send a note to Mr. Taylor.

MARY ANN ELLIOTT, a widow, residing on Hampton Common, was then called. Her testimony corroborated that of Ann Ellam. She saw Frances Clark first between five and six on Sunday evening, and found her very ill. On Mr. Bowen's arrival in the morning, he made examination, and said "the child was lodged at the hips," turned it, and added "that he had put it in a fair way for the world," but that it was dead. She saw Mr. Bowen use the instruments on the Monday night. Of their nature she knew nothing. He was very much out of temper, because another medical gentleman was spoken of. Witness told him that it was of no use to say—Send for any one you like—she knew of nobody that would come without a note; there was a man waiting at the door, if he chose to send him to another doctor, or if he named any gentleman whom he wished to come, she would send for him. He said he would do no such thing. The friends then sent for Mr. Taylor, as the only one they could think of; and the reply of that gentleman was, that he would come instantly on receiving a note. Mr. Bowen continued to use his instruments until three o'clock on Tuesday morning, and then said he must go home and get some more from London. He returned in less than an hour and asked for the boot-hook, which he used, placing his feet against the bed, and pulling with violence. She heard "a slushing noise" when the hook was used. (The boot-hook was shown, and compared with the blunt-hook.) Witness saw him take off both of the arms; one he pulled off, the other he cut away. The manner of Mr. Bowen was extremely cross and snappish, both to Frances Clark and herself. She had attended many labours before, but none like this.

SARAH CHILMAN, the midwife, a widow, residing at Kingston, was next examined. She said she had practised thirty years, and assisted at the births of 4000 children. To questions—Since your experience has been so great, why did not you deliver the deceased? Because it was not my work; a man was sent for, and then the business was taken out of my care. Have you ever delivered Mrs. Clark before? Yes, several times.—Were the labours difficult? Always; two nights have sometimes passed.—Why did you send for a doctor now? Because it was not a fair labour, and I always send for a doctor in proper time, as his advice is better than an old woman's; when Mr. Bowen came, he said Mrs. Clark would do very well, and there must be patience.

This was when he attended in the morning. In the evening he still said there must be patience, but witness thought not. She said nothing at first, for she was "glad of somebody, to get her own neck out of the halter." At last she spoke, and said that in these cases they always had another doctor, but Mr. Bowen said they did not want any more. Witness then mentioned Mr. Taylor to the deceased, who had "helped her out once before." Mr. Bowen said, that if Mr. Taylor came he would go out of the house. This was not a hand case; it was what witness would call a face case. The face filled the cavity, and there was no room for an arm. The arm had not protruded when Mr. Bowen came. When the arm came off he had got a napkin round it, and was pulling very hard, and witness said "the Lord a' mercy on us, what are we to do now; we must have more assistance." The pelvis was sufficiently large for any child.

*Examined by Mr. Jewell.* When were you called to the case? Between six and seven on Sunday night. The membranes gave way at eleven. Discovered that it was a face presentation next morning at eight. The pains came on at periods of half an hour, and never bore down. Saw nothing whatever taken away but the arms.

Here the evidence of the witnesses present at the labour closed, and—

Mr. GEORGE JEWELL was examined. He is a surgeon and a teacher of midwifery, and was present at the examination of the body this morning, and had heard the evidence. As to the position of the child, he should imagine that the only part which could have been felt was the cheek. It could hardly be called a face presentation, and he should say from the position of the body that the arm must have fallen down. As to the practice of removing the arms under such circumstances, he considered it to be perfectly justifiable. When the arm is presented in that manner it is not always usual to perforate the head, but sometimes it may be done with great advantage. The practice in general is to bring down the breech by an instrument of this kind (exhibiting the blunt hook), and if there be not one at hand, and the practitioner thought proper he might use a boot-hook in its place. From the spine being broken in the fetus in the present case, he should think that Mr. Bowen had used the boot-hook for that purpose. He (Mr. Jewell) would use it himself if the patient were sinking for want of an operation of that kind. There did not appear to have been any injury done to the soft parts or the uterus, from the use of instruments. [To questions.] Is it your opinion that the medical man was, or was not to blame in the treatment he adopted?—I have stated

my opinion already.—In case of the head being so impacted in the pelvis, that the hand could not be introduced, would it, as in this case, be proper to introduce the instruments?—No answer. What was the size of the hole in the scalp?—Large enough to admit the point of the middle finger. Was it easy to extract the brain through that hole?—If the brain were broken down it could escape through a very small orifice. Is it usual to take off the arms?—The child was unusually large. Could you discover from the state of the fetus that it could not have been turned?—It could have been turned only with difficulty; the chin was towards the pubes. Is it usual to take off the limbs without further advice?—I have expressed my general opinion. How could both arms have been taken off?—When one is off, then there is more room to take off the other. Should you, from the evidence you have heard, and the position in which you found the fetus, have pursued the same course?—(There was no direct answer to this question; the further examination of Mr. Jewell was very much opposed by some friends of Mr. Bowen.) Do not you in your lectures require your pupils to ascertain the position of the child?—(Not replied to.) Do you think that Mr. Bowen acted properly in this case?—I do.

Mr. GEORGE TAYLOR, of Kingston, was called and examined. Is a surgeon and an M.D., has been eighteen years in practice; attended Frances Clark's first labour; she had a full-sized pelvis. In that case he turned the child, and there was a fair delivery. On the present occasion he received a message between one and two o'clock on Monday night, to go to Hampton. He asked the messenger what was the woman's name, and the duration of the labour, and heard that Mrs. Chilman and Mr. Bowen were in attendance. He inquired whether the messenger came from Mr. Bowen or the attendants; they said, not Mr. Bowen, for he refused to send. Did not know Mr. Bowen, nor does he now, and his opinion therefore was, that Mr. Bowen did not wish it, nor said any-thing about it. His reply accordingly was that he could not go unless invited by Mr. Bowen himself. In the morning he wrote to say what had passed, and presumed all had gone off well. He had never heard any more of Mr. Bowen until now. He had been present at the examination of the body. He thought it impossible that the arms came down naturally. The face might have righted itself. Thinks the arms came down in an attempt to get hold of the feet. It is not usual to take off the arms of the fetus, and should not readily be induced to do such a thing himself; cannot call to mind a case in which he saw the propriety of such an operation.

Sir ANDREW HALLIDAY, examined by Mr. Guy. The questions put to Sir Andrew went to show that Mr. Bowen had stated to Sir Andrew that he had not taken off the arms of the fetus, and had safely delivered the woman. The following is the substance of the reply of Sir Andrew. Mr. Bowen called on him shortly after the death of Frances Clark, to explain the reports which were in circulation. His language to Sir Andrew went to prove that he was not to blame in the treatment he adopted. He did not say that he had not taken off the arms and delivered the woman. It was impossible for him (Sir Andrew) to recollect now exactly what passed, but the impression left on his mind, by the statements of Mr. Bowen, was, either that he *had* delivered the woman, or that he was in the act of delivering her when she died from exhaustion. He (Sir Andrew) did not mean to deny that Mr. Bowen had said this or that, but his impression was as he had already described. [To questions.] Did you not tell Mr. George Taylor, and Mr. Sells, that Mr. Bowen had said to you he had not removed the arms and had delivered the deceased?—I told them that Mr. Bowen told me he had not *twisted* or *torn off* the arms. (Objections were here made to what was termed a "personal examination," and it was therefore stopped.)

Mr. Wm. Sells of Hampton, Mr. George Cooper of Brentford, Mr. James Smith of Richmond, Mr. Thomas Litchfield of Twickenham, and Mr. John Watson, Surgeons, were now sworn, but the coroner and the jury seemed to think, that farther evidence was not required. Mr. Smith and Mr. Cooper said they should be obliged to give evidence which would be of a contrary nature to some of the medical opinions which had been given by Mr. Jewell, and Mr. Cooper remonstrated with great force and justness against the custom of requiring the attendance and evidence of medical men on coroners' inquests, without remunerating them for the valuable moments which they were often compelled to devote to it. He had put a lady to bed at ten o'clock the night previous, and had not seen her from that hour to this (six p.m.), in consequence of the summons he had received to attend here, though without one particle of previous knowledge of the merits or demerits of the case. The justice of the complaints made by Mr. Cooper were fully acknowledged by all the gentlemen in the room. We are sorry that want of space prevents us from appending the whole of his remarks on the hardship to which medical men are thus subjected.

Amidst the discussion which ensued some reflections were thrown out against the mode in which the warrants were filled up by Mr. Guy, who was justified by the

coroner. The mode of selecting the jury, adopted by the curate of the parish, Mr. Merrywether, as it appeared, was also deprecated, and upon very just grounds.\*

The coroner "summed up" about seven o'clock. He commented very briefly on the evidence of the witnesses. It was impossible to say why (he observed), but some men were naturally more careful, some more timorous than others; and so it was, he supposed in midwifery cases; some went forcibly to work, and some gently, but they were not therefore to think of bringing every man to the bar of public opinion because his mode was not so successful as that of others, else they would have enough to do with all the medical men and old midwives in the kingdom. He did not mean that it should be bruited about that the arms of "children"† were to be cut off on all occasions, but he considered that there were occasions in which it might be done with great propriety. The Princess Charlotte had, he had no doubt, the very best physician when she was in child-bed; how much more excusable then, was an unfortunate result to a less eminent man. Now the medical man, in the present case, had evinced great anxiety, and had shown himself desirous of doing all he could. He procrastinated the use of instruments as long as he could, and they (the Jury), knew the fatal result. Let them observe the length of attendance he gave to the patient; he did not shirk the case at all; he did not make a half business of it, but persisted to the last. As for the boot-hook, it was so similar to the blunt-hook, that a man would be happy to have such a substitute; yet this had made a great impression out of doors. He had used his best skill, and it had turned out unfortunately, and could not be helped. It was for the jury to say whether Mr. Bowen stood in the case of a man who ought to be tried for the course he had pursued.

After a consultation of a quarter of an hour, the jury brought in a verdict of "Died by the visitation of God, and the medical attendant did all he could to save life," or, "there was no blame attached to the medical attendant."

\* The Rev. Mr. Merrywether, in the course of examination, admitted that he gave the constable, who was appointed to summon the jury, a list of twenty-four names. He also admitted that he had never interfered in a similar manner on any former occasion. The juryman appeared to be far above the class of persons who usually act on coroners' inquests.

† The non-medical coroner swore all the witnesses to give true evidence "touching the death of Frances Clark and her infant child!"

## THE LANCET.

*London, Saturday, October 9, 1830.*

Few institutions of modern times have so strongly excited the hopes of the *litterati* of Europe as the UNIVERSITY OF LONDON. The proposition for founding this splendid national establishment was hailed by every liberal mind with unqualified delight, because it was expected that it would freely shed the light of knowledge over the immense mass of uninstructed beings resident in this densely-populated metropolis. If the expectations of the friends and supporters of the new University have not been fully realized, still we believe that enough has already been accomplished to satisfy the public that incalculable advantages must, ultimately, result from the intellectual labours displayed in such an establishment. Of the success of one department we can speak with much confidence; we mean, the medical. That its utility has in some measure been retarded by the influence of private pique, and the workings of jealous malignant bickerings, we shall not attempt to deny; but these are incident to all infant establishments, in which a mass of ill-assimilated and incongruous matter must at first be associated, and the difficulties which the University has already proved itself equal to surmounting, afford the strongest ground for believing that the medical department, will become the first institution of its kind. The two great difficulties under which this department has laboured, have arisen, it must be confessed, from defects in the government. We allude to the election of the professors by private testimonials and in secret, instead of by competition and in public; and to the extreme, the culpable negligence, manifested in the absence of a hospital. Had the professors been elected by *concours*, as in Paris, the University would at once have

furnished a splendid exception to the secret, and unworthy method, universally adopted in this metropolis, of appointing professors, teachers, and officers, to the whole of our medical establishments. Mr. BROUGHAM openly declared, even at the preliminary proceedings, that any other consideration than ability should only weigh as dust in the balance in appointing the professors. Yet, in defiance of this excellent declaration, all the professors have been selected in secret, and the council, we believe, have been guided in their choice, solely by testimonials that have been written in private, read in private, and discussed in private. Many of the professors in the medical department are gentlemen of the highest attainments in their profession, and they would have been delighted at having had an opportunity afforded to them of displaying their talents before a scrutinizing, and liberal, public. The council must now deeply regret that election by public competition was not adopted, for to that fatal omission are to be traced, the charges of incompetency which have been so freely and so extensively circulated against some of the professors. In the present day the gown of a professor is not deemed a sufficient guarantee for intellectual attainment, and, in spite of all that can be said to the contrary, the people will assuredly believe that there is something wrong, something corrupt and underhand, if those who appoint important public officers select them in the closet, instead of in the open face of day. In the choice of professors, therefore, we fear it must be acknowledged that the Council of the University of London are not one step higher in the scale of good government, than are the ill-informed and idle managers of our ill-officered dispensaries. This is a subject of vital importance to the interests of the University, and we would seriously urge it upon the notice of the proprietors at their next annual meeting.

The consideration, however, of the other

difficulty, under which the medical department has laboured—the absence of a hospital, must not be delayed until February, unless the council and proprietors are really desirous that the medical school should never embrace a greater number of students than it contains at present. The success which this department has already attained in the absence of a hospital, speaks loudly and decidedly in favour of the exertions and qualifications of the professors, who, without such a prop, such an auxiliary to their labours as a hospital would afford, are, in fact, endeavouring to stem the torrent of prejudice that has been opposed to them, with a millstone around their necks. The support which we have, by our humble exertions, endeavoured to yield to the University from the first moment of its establishment, justifies us in speaking boldly; without then attributing bad motives to any one, we declare unhesitatingly, that those who have opposed the foundation of a hospital in connexion with the University, are utterly unqualified to take any share in the government of the institution. After the hopes that were originally held out, is such conduct honourable to the public? Is it just towards the proprietors? Is it fair towards the students—the anxious, the hardworking, student? The public will, by-and-by, declare that they have been deceived; the proprietors, when the shares shall have sunk *fifty per cent.*, will declare that they have been cheated; and the students will quit an institution in disgust, in which they will have too much reason to complain of the non-fulfilment of their just expectations. A medical school, upon an extensive scale, cannot exist without a hospital. As well might an animal be expected to live without nutriment. In the wards of a hospital there are all the materials upon which the principles and practice of the curative art are founded; but theory, in the absence of an opportunity for observing the facts upon which it is founded, assumes the character of vague hypothesis, and is equally worthless. But it were a waste of time to dwell upon the propriety of attaching a hospital to any medical school. Nearly the whole of the medical students visit the metropolis for the express purpose of “walking the hospitals,” as it is termed. They consider, in fact, that the hospital is the school, and the lecture-room only the appendage. It should be remembered that the best works on medicine, surgery, physiology, and pathology, have been always open to them during the period of their initiatory studies; and in the lecture-rooms of this town they have little more repeated to them in the course of each day, than the discourses contained in established works, and with which they have long been familiar. They come to London to see disease, and to see those means applied which the accumulated experience of ages has decided to be the most judicious and efficient. But, at the London University, there is no disease to be seen, no disease to be cured, no experience to be acquired. They can observe the shadow, but the substance is beyond their scan. It will be said, we are aware, by the enemies, not by the friends of the University, that the pupil can attend the Middlesex Hospital. But the practice of this institution has long been in ill odour throughout the kingdom, and the Hospital was not erected with a view to the formation of a medical school. Its regulations are obnoxious to the adequate instruction of students, and the governors, when the prospectus of the University was first issued, even took the opportunity of disclaiming, in the public papers, any connexion between the hospital and that institution. This proceeding ought, indeed, to have goaded the Council to the performance of their duty. The insult, however, for it was one, has passed unheeded. We have heard two grounds alleged to explain the cause of the absence of a hospital; first, the opposition offered to the measure by Mr. CHARLES BELL, and, secondly,

the want of adequate funds. If it be true that Mr. BELL has opposed the establishment of a University Hospital, the Council must have been particularly short-sighted not to have perceived that it was possible, quite possible, that his hostility to the measure arose from motives not entirely disinterested. The erection of a hospital upon the foundation of the University might not have proved agreeable, or even profitable to Mr. C. BELL, who, it ought to have been remembered, is one of the surgeons of the Middlesex, and, hence, he is the only anatomical professor connected with the University, who is in receipt of the fees paid by the students for witnessing the surgical practice of a hospital. It is, we say then, barely possible, that Mr. BELL's opposition may have been stimulated by motives not the least calculated to add to the honour of the University, or to promote the interests of the students. If there were a University hospital, Mr. Bell would not be the only medical professor holding the office of hospital surgeon; he would not be the only professor whose coffers would be benefited by the fees paid by hospital students. Besides, Mr. BELL may be apprehensive that the enlightened views and liberal opinions of the Council might induce them to act upon the Parisian principle, and throw open the wards of the hospital to the students, free of expense. In this case the surgeon of the Middlesex Hospital would be *minus* his fees. Mr. BELL, therefore, sees much hazard in the enterprise, and he has invariably touched the subject with a cold and chilling hand. However careful Mr. C. BELL may be of his own interests as a hospital surgeon, we think he might have paused, as one of the professors, before he had taken upon himself to issue a document, the tenor of which, if it were left unexplained, might injure, if not ruin, that department of the University which he is bound, by every principle of honour, to uphold to the utmost extent of his capability.

Having derived our information from the most authentic sources, we are bound to credit the report that Mr. BELL has thrown difficulties in the way of establishing a hospital in connexion with the University. If the reports be unfounded, then, of necessity, the whole of this part of our argument falls to the ground; but assuming them to be correct, what inference are we to draw from the following *verbatim* copy of a paper which is exhibited in the lobby of the Middlesex Hospital?

“CLINICAL LECTURES. SURGERY.

“Mr. Bell has delayed saying any-thing about Clinical Lectures on Surgery, in the hope that he will be able to make an arrangement with Mr. Brodie, that the pupils of the Middlesex and St. George's Hospitals, may have the mutual benefit of more extensive opportunities for learning the principles which direct the practice of the hospital surgeons of London.

“The surgeons of St. George's Hospital have expressed themselves most liberally on the subject.”

Here, Mr. BELL in so many words announces to the pupils, that no clinical information is to be obtained at the University, and not sufficient at the Middlesex Hospital, but that he hopes to be enabled to make an arrangement with the surgeons of St. George's, which will be attended with advantage; thus drawing off the attention of the student from the University, and directing it to a school situated at a distance of two miles. Now, if Mr. BELL be so ready to acknowledge that the University affords no materials for conveying clinical instruction, that the wards of the Middlesex Hospital are also inadequate to the purpose of teaching medical students how they are to practise their profession, why does he—and the council have a right to demand an answer to the question,—why does Mr. BELL oppose the erection of a hospital in immediate connexion with the University? It certainly is very consolatory to those students who have paid to be instructed at a school in Gower-street, to be told by one of their

own professors, that they can obtain a little knowledge by walking to St. George's Hospital, situated at Knightsbridge, where the surgeons, "express themselves liberally on the subject!" Would that we could say as much for Mr. BELL, and we regret, exceedingly, that the members of the council should have been at any time influenced in their decisions, by a person who appears to be so little desirous of securing the success, and promoting the great objects, of their institution. Mr. BELL is an able anatomist, and an acute physiologist, but we fear that he is wanting in those high qualities of the mind which should alone regulate the principles of government in such an excellent establishment as the University of London.

The second alleged obstacle to the formation of a hospital, viz. the deficiency of funds, has, we believe, had much greater weight with the council than the opposition of Mr. BELL; but it is a difficulty which energy and talent, might long ago have surmounted. Within very little more than the time that the council have been lamenting over the sadly empty state of their coffers, some persons of very questionable character and intentions, have contrived to collect "building funds" sufficient to erect a new St. George's Hospital, a new Westminster Hospital, and another institution, which is to be called the Charing Cross Hospital. In the list of proprietors of the University of London are to be found the names of noblemen of wealth, character, and influence; also the names of merchants, and tradesmen, of great opulence. Who can believe then, that had the necessity and utility of the measure been properly explained to them, they would have withheld from such a scheme either their personal exertions, or their pecuniary contributions. Besides, if the public have subscribed so liberally to the hospital building funds now accumulating, is it to be supposed that the benevolent part of the community would have with-

held their donations from an object of so much more importance than either of the institutions now in progress?

The expense of maintaining a *well-governed* hospital, is much below what is generally conceived to be adequate for such a purpose. Three or four thousand pounds *per annum* would be quite sufficient to support a hospital large enough to afford instruction to the students of the University,—a sum, we should think, not difficult to be collected amongst even the proprietors and their friends. In a pecuniary sense, indeed, we are decidedly of opinion that the shareholders would be benefited by individually subscribing five or ten guineas towards the erection of a hospital; for one of the speedy results of founding such an institution, would be an increase in the value of the shares of not less than from five to ten *per cent*. If a hospital, indeed, connected with the University, were to be governed upon liberal principles,—if its officers were to be elected by public competition, and if its doors were to be thrown open, free of cost, to the medical students, it would receive warmer support than any other eleemosynary medical institution in this metropolis; because it would be soon acknowledged that it must eventually confer incalculable advantages upon all classes of the community.

Let us hope, then, that the members of the Council will at once bestir themselves, and devise some plan for accomplishing this great national work. The measures, if judiciously taken, must prove effective. In order to stimulate the Council to the performance of this duty, and in order not to add to the numerous fatal effects which have already arisen from delay, we would suggest to the students the propriety of addressing the Council on the subject, urging in strong, but respectful language, the disadvantages under which they labour from the absence of a hospital, and imploring that measures may be immediately adopted for founding

such an institution,—without which, they can unhesitatingly state, that it is not in their power to acquire a competent knowledge of their profession.

### WESTMINSTER HOSPITAL.

THE scheme for rebuilding the Westminster Hospital at Charing-Cross was discussed by the Governors at a tolerably full meeting on Wednesday last. After a warm debate, it was decided by the casting vote of the Chairman, who was himself the Treasurer, that “the Treasurer’s report should be brought up.” And this appears to have been done merely out of courtesy to that respectable gentleman. The jobbers, therefore, are in *statu quo*. There is no district in London where a Hospital is more decidedly necessary than the one in which the Westminster Hospital now stands. We shall publish two or three documents on the subject of this transaction in our next number; meanwhile we hope the intelligent and independent Governors will not fail to perform their duty to the subscribers and to the afflicted poor.

A REPORT of the Coroner’s Inquest which was held on Saturday last at Hampton, will be found at page 74. The facts disclosed in the evidence of the females, require no comments; but we must acknowledge that we are utterly at a loss to comprehend the evidence of Mr. JEWELL. Should there have been any young and inexperienced practitioners present, who may have formed an opinion from the testimony of that gentleman in favour of using great force in the practice of midwifery, we beg to submit for his careful perusal the following extracts on the subject; the first taken from Professor DAVIS’s splendid work on the “Elements of Operative Midwifery,” and the second from the invaluable lectures of Dr. BLUNDELL, published in the volumes

of THE LANCET for 1827-8. This was another nice case for a non-medical coroner!

“The requisite amount of force to be used in obstetric operations, should be applied by degrees, very cautiously and slowly, according to the demand for it; but the whole of the extracting force, in order to be safely, and, therefore, successfully exerted, must be confined within very moderate limits.”—*Elements*, p. 201.

“When the arm of the child is presented in the way I now show you, provided the woman have reached the full time of gestation, you cannot in this position abstract the child. If, with FEROCIOUS IGNORANCE, you lay hold of the arm and pull, torturing the innocent child, like Damien the assassin, you break, you tear it, limb from limb.”—LANCET, p. 284.

Passages bearing on the same point might be multiplied *ad infinitum*, but a very small portion of common sense, without the authority of any established writer, must be quite sufficient to deter any man from following the example of Mr. Bowen in pulling off the arms of a full-grown fœtus, after he had “set every thing straight for the world.”

FROM a report which M. LARREY lately made to the Académie Royale, it appears that, of about 500 wounded who were admitted at the Military Hospital at Gros Caillou, after the three memorable days, not more than seven had died on the 29th of August, although a great number of them had undergone very important surgical operations.

With respect to the personal exertions of M. LARREY during and after the three days, the French journals are unanimous in their praises, and it gives us great satisfaction to find that this venerable man, who, during the old regime, was purposely neglected, merely because he had been the personal friend of Napoleon, has lately received from the present government the most unequivocal proofs of a frank acknowledgment of his merits.

*On the recent Improvements in the Art of distinguishing the various Diseases of the Heart, being the Lumleyan Lectures delivered before the Royal College of Physicians in the year 1829.* By JOHN ELLIOTSON, M.D.F.R.S., &c. &c. London. 1830. Longman and Co. Folio. pp. 36.

ALTHOUGH some years have now elapsed since the invention of the stethoscope, and several treatises, besides the translation of Laennec's original work, have been published in this country respecting it, its value is by no means so generally acknowledged as it deserves to be; and there are yet many practitioners, and some writers, who either reject it altogether as worthless, or maintain that it is only to be used with advantage by such as have a peculiarly nice ear, and have devoted to the study of it an extraordinary degree of time and attention. It is therefore with great satisfaction that we find such strong testimony in its favour from a physician whose statements are justly entitled to confidence, and who himself furnishes a refutation of one of the objections which have been adduced against auscultation, having first begun to employ it after many years of practice, and when it can hardly be supposed that he could devote to it more time than almost any practitioner might bestow. Without noticing this objection, Dr. Elliotson, in the commencement of the first lecture, successfully combats those which have been raised against the utility of auscultation, and his observations here are so excellent, that we cannot forbear making as long an extract as our limits will allow of.

"The discoveries made by Laennec in the symptoms of these disorders are great enough to entitle him to all the honours which have ever been acquired in our profession. He has enabled us to judge of diseases, often not otherwise with certainty distinguishable or not at all, and this with an accuracy inconceivable to those who are unacquainted with his investigations; to distinguish diseases of the heart, which were formerly, and are still too often all, either expressed by the easy term disease of the heart, without a specification of the parts affected in this complicated organ; or as often passed over entirely, while the case is mistaken for hydrothorax, or some pulmonary affection, and to distinguish diseases

of the lungs, which, in many cases, could not be pronounced upon with accuracy, of which, in others, the diagnosis was always uncertain, and moreover to point out the very part affected.

"But the very accuracy of Laennec's discoveries is objected to. We are asked *Cui bono?* The answer is plain. It is universally allowed that every disease should be described, and its nature ascertained, as accurately as possible. Now with every advance in accuracy of description, and in knowledge of the source of symptoms, diagnosis imperceptibly and inevitably becomes more accurate. To condemn accurate diagnosis is therefore to condemn accurate knowledge—to rest satisfied with imperfect information when industry would give us more—to admire ignorance when knowledge is within our reach. Besides, diagnosis ought to be universally cultivated without reference to its utility in particular instances. It is a part of our science; every part must be cultivated for the perfection of the whole, and what may not be practically useful to-day, may become so to-morrow, &c.

"But there is immediate utility in the discoveries of Avenbrugger and Laennec. No one will pretend that the diagnosis in chronic diseases of the chest is, with the exception perhaps of phthisis, generally satisfactory. Before I adopted auscultation, I know that I frequently discovered disease of the heart after death where I had not previously suspected it, and frequently found the organ sound when I had supposed it diseased. When I was correct in expecting to see organic affection of the heart, I was often wrong as to the precise nature of the lesion. Too often has auscultation at once revealed disease of the heart to me, when, by good practitioners, no affection of the heart, or even of the chest, had been suspected, or the case had been named nervous palpitation or asthma, when the lungs had been regarded as the seat of the malady, or the case been treated with the more violent remedies of hydrothorax. Repeatedly have I seen chronic bronchitis, with extreme congestion of the lungs, mistaken for hydrothorax, and unavoidably so, from the omission of percussion and auscultation, because the symptoms were precisely the same, with the exception of those which percussion and auscultation only could disclose. Inflammation of the substance of the lungs takes place continually during other diseases, without being obvious before death to any but the auscultator and percussor. Without the aid of the ear, who can ever distinguish emphysema of the lungs, or in every case pneumato-thorax? Both may be readily mistaken for hydrothorax," &c.

Although these lectures cannot be con-

sidered as forming a complete account of the diseases of the heart, and are intended more especially to show the importance of auscultation, they are by no means exclusively devoted to it, and contain much valuable information on the morbid anatomy of this viscus, and on the other means of distinguishing its affections, the employment of which Dr. Elliotson is not inclined to dispense with, even where the diagnosis might appear to be firmly established by the stethoscope alone, observing,

"The general symptoms may each, however, be highly useful, when viewed by the side of the symptoms discovered by auscultation; they may confirm the diagnosis, or, rather, they may unite with these into a satisfactory theory of the nature of the nature of the case. They should never be neglected, because all the phenomena of every disease deserve the attention of a good practitioner."

It would answer no good purpose were we to follow the lecturer in his descriptions of disease, or the details of cases, in support of his statement, for these are scarcely capable of condensation, and ought to be read in connexion, to be fully appreciated. We shall, therefore, conclude our review with some of his observations on the natural and healthy action of the heart, in which he defends Laennec's theory from some objections which have been recently started, and especially against the opinions of Dr. Corrigan, which we had very lately occasion to lay before our readers. After describing the nature and rhythm of the sounds of the heart, according to the statements of the French physician, and the changes which are induced in them by disease, the lecturer goes on to say,—

"Laennec's correctness, in ascribing the first of the two sounds of the heart's action in health to the ventricle, and the second to the auricle, has been called in question, some asserting that the first sound is the result of the auricular contraction, and the second of the ventricular; some that they occur at the moment of the dilatation, not at the moment of the contraction of the cavities; and some that Laennec was right in regard to the ventricular sound, but that the second sound cannot arise from the contraction of the auricle, as Harvey, Haller, Senac, all declare that the auricle may be seen to contract immediately before the ventricular action; and they consider, therefore, the sound which follows the ventricular, to be produced by some unknown

cause, and the auricular contraction to be without sound, two very singular and very considerable suppositions. The alteration of the sound in narrowing of the respective openings proves, I think, that Laennec is right; for if the opening from a ventricle is narrowed, the healthy sound ascribed by Laennec to the ventricles is altered; and if the opening from an auricle is narrowed, the healthy sound ascribed by him to the auricle is altered. An argument, in favour of the priority of the auricular contraction, has been deduced from the veins of the neck, in some cases, regularly swelling, immediately before the pulse is felt. But the obstruction in the auricles causing this swelling does not, I apprehend, occur during their contraction, for at that moment there is a free space in the ventricles to receive the auricular blood, and it is only a part of the auricle that has the power of contraction. The obstruction which produces the swelling must take place as the ventricle becomes filled, and the auricular blood consequently accumulates, and therefore the swelling of the veins must be expected when the ventricles will receive no more, viz., immediately before they contract, or while they are contracting. There is no wonder, therefore, that the arteries, according to this account, beat first; then a second sound of the heart is heard, I presume the auricular action; and then a short interval occurs before the veins pulsate—before the blood accumulates in the auricles previously to their contraction. The jugular veins are said, by some, always to be dilated quite synchronously with the pulse of the arteries."

"Since the delivery of these lectures, Laennec's accuracy has been called in question by others, and the stroke of the heart's apex, and the first sound of the heart, declared to happen before the pulse, and to be produced by the dilatation and repletion of the ventricles; and the second sound to occur at the moment of the contraction of the ventricles, and to arise from the flapping of the parietes of the emptied ventricles together.

"I would reply in the first place, as before, that when an obstruction exists at the mouth of the aorta, or pulmonary artery, a morbid sound occurs at the moment Laennec supposes the ventricles to contract, and when at either auriculo-ventricular opening, at the moment he supposes the auricles to contract. This could not happen had he mistaken the periods of the ventricular and the auricular contractions. Secondly, when the pulse at the wrist follows the stroke of the heart, it does so after only a very minute interval—such as may be explained by the distance of the radial artery from the heart—and actually occurs decidedly *before*

the auricular sound, that which is now declared to be the ventricular. Moreover, when the pulse at the wrist is observed to follow the stroke of the heart, the pulse at the innominata (so much nearer the heart) may be found to precede that at the wrist, and to occur all but simultaneously with the heart's stroke, so that the relative distance of the parts explains the whole difference, and the pulsation of the arteries in all cases clearly arises from the stroke of the heart. If an artery is observed still nearer the heart than the innominata, no interval between its pulse and the stroke of the heart is perceptible. In four cases of aneurism of the ascending aorta, producing a strongly-pulsating tumour to the right of the sternum, this and the heart, when the fore-fingers were placed upon both, were felt, and by all seen to pulsate quite synchronously. When the obstruction is at the mouth of the aorta or pulmonary artery, the preternatural sound I have always noticed synchronously with the pulse; when at an auriculo-ventricular opening, in the intervals of the pulse, after or before it. It sometimes, in the latter case, is so prolonged as to last till the pulse is again felt, so that there is no interval, but merely an equal alternation of the ventricular and the preternatural auricular sound; or even an interval occurs after the ventricular stroke, probably from the auricle not being disposed for contraction at the usual time, on account of its contraction having been so lengthened by the difficult escape of its blood, that a longer repose is required than just during the ventricular contraction; here the auricular sound occurs first, then the ventricular, and then the interval.

“Thirdly, the sounds considered by Laennec to be auricular and ventricular are heard loudest both in health and when morbid, at the seat of the auricles and ventricles respectively.”

The only fault we have to find with these lectures is, that they are published in the folio, rather than the more convenient quarto form, when the plates, which are very well engraved from beautiful and accurate drawings by Mr. Alcock, might have been equally well contained in the latter.

---

*Practical Remarks on the Nature and Effects of the Expressed Oil of the Croton Tiglium, with Cases illustrative of its efficacy in the cure of various Diseases.* By MICHAEL JOHN SHORT, M.D. London, Longman. 1830. pp. 63.

In the construction of this little treatise, Dr. Short has shown considerable industry,

and an intimate acquaintance with the older literature of medicine; the first division of his pages, is, in fact, a miniature cabinet of the several curiosities connected with the history and applications of the croton tiglium, authenticated by the venerable names of Rumphius, Rheed, Jacob Bobart, Bergius, Laureiro, and a host of similarly euphonous appellations. The ponderous Latin of these writers, Dr. Short has faithfully (we fear injudiciously) committed to his pages, and certainly to the few who can understand the monastic barbarisms these quotations present, he has afforded a curious and entertaining compilation.

In the second division of his pamphlet, the author adduces a body of irresistible modern evidence, in proof of the superiority of the genuine croton oil over other cathartics, in the treatment of the several diseases in which remedies of that description are required. On this point, however, we are inclined to believe, that the minds of medical men are already sufficiently decided, such of them, at least, as have kept pace with the improvements in their profession, and whose studies have not terminated with the receipt of their license to kill, from the beadle of a College. There are still in existence, it is true, some hundreds of medical “old wives,” who, under any circumstances, would as readily administer a drachm of arsenic, as a drop of Dr. Short's purest cold drawn croton oil, and for the consternation of these ladies, we are forced to mention, that Dr. Short's heretical innovation on the supremacy of Glauber and jalap, even extends to the administration of the oil of croton in abdominal inflammations.

“If there be any inflammatory action,” he says, “going on in the intestinal canal, either from external causes, or from the presence of irritating matter within, the oil will be found the most effectual application, as it will remove the cause or irritation sooner than any purgative with which I am acquainted, and at the same time diminish inflammatory action more speedily, and in my opinion more effectually, than even the abstraction of blood. As a proof of these assertions, I have selected the following case from many similar ones, which occurred to me in my practice in Madras, during a period of four years; not because the effects of the exhibition of the oil were more obvious or satisfactory, but because, as the ordinary mode of treatment had been fre-

quently applied before in the same patient, and under the same circumstances, we are thus enabled to institute a comparison, and this case is consequently more conclusive.

"*Case.*—A lady of nervous temperament and bilious habit, aged about 35, came under my care, labouring under a severe attack of bilious cholera, a complaint of which she had had frequent and serious attacks. I found the vomiting of black bilious matter and the purging excessive. Wishing to evacuate the contents of the bowels as soon as possible, I ordered one drop of the oil, *tiglii*, in *zij* of syrup, to be given every four hours, and told the lady to drink freely of barley-water. Three doses of the medicine completely cleared out the bowels, removed the spasmodic action, and appeared to have restored the healthy action of the liver, for, on the next day no ailment existed, the appetite had returned, and on the evening she said she felt quite well. In all her former attacks, she had been treated with large doses of opium, which produced great stupor without relieving spasm. Calomel, and the other usual remedies, had also been applied, and it was generally upwards of a month before she had perfectly recovered."

To many, we believe, the "inflammatory" character of this case may appear by no means a decided matter, and we must admit that it is deficient in what should be considered the strongest contradictory symptom of the use of any *acid* cathartic, namely, abdominal tenderness. Dr. Short, however, advances other cases, which we have not space to quote, but in which this symptom was strongly developed, and in which the cure seems to have been mainly effected by the liberal administration of the croton oil.

The motherly members of our profession will further be not a little amazed at Dr. Short's homicidal audacity in prescribing this medicine in sundry diseases of infancy and childhood; yet so it is, and numerous are the records of its effects which the Doctor details. What will the tender prescribers of manna, and of rhubarb and magnesia, and of peppermint-water, and castor oil, say to this atrocious mode of curing convulsions and hydrocephalus? Still we must make the confession, that we have been accomplices in such practices ourselves, that like Dr. Short we have given the croton oil to children two years old, and in every instance had reason to acknowledge its beneficial virtues. In truth, we know no medicine so admirably adapted to the numerous disorders which arise at this early age from

over distension of the alimentary canal, whether we regard the quickness and certainty of its operation, or the extreme facility with which, for obvious reasons, its administration can be effected.

But perhaps the most remarkable character in Dr. Short's publication is his recommendation of the croton oil as an *external irritating* application. On this important subject the author's words are as follows—p. 63.

"It will be perceived also that I have employed it in some cases externally as an irritating liniment; I am not aware that its application in this way has been practised or noticed either in this country or India.\* I am however decidedly of opinion, from the experience I have had of its efficacy as a counter-irritant, that it is preferable to all those now in use; superior to the cantharides in the quickness and certainty of its operation, and in the permanency of its effects to the ointment of tartarised antimony, for the same reasons, as well as for not producing that excessive pain and constitutional irritation which usually attend the application of the last preparation, and to the common sinapisms, because it stimulates the skin much sooner, diffuses more warmth, and can be better regulated as to the extent of its effects. I have employed it in this way in cases of acute and chronic rheumatism, it gout, in tic 'douloureux, in glandular and other indolent swellings, and in all these cases with the most satisfactory result."

With these remarks and quotations we close our notice of Dr. Short's *treatise*. On Dr. Short's *croton oil* we are however obliged, in justice to that gentleman, to offer a passing comment. There is scarcely a drug the apothecary purchases, but before it reaches the consumer is liable to be subjected to the basest and most thwarting adulterations; it is with pain we add, that in Great Britain there is not more than one establishment in twenty, free from this deadly and abominable traffic. Thus, in the instance of the croton oil, we have known it to be simply diluted with castor oil, or with sweet oil; to have been imitated by euphorbium resin dissolved in castor oil, by the expressed oil of the *Jatopha* *Circas*, and, strangest of all, by common

\* Dr. Short forgets that the external application of the croton oil is expressly mentioned in the *Materia Medica* of Hindostan as a part of the treatment of rheumatism, by the native practitioners.

train oil allowed to become rancid, in order to acquire an acrid flavour. To detect these adulterations, Dr. Nimmo, of Glasgow, proposed a test just as fallacious as its certainty was desirable; and as no other has yet been pointed out, the profession and the public are left without any resource but the dependence they may place on the quarter whence they obtain their supply. We are happy, therefore, to be enabled to recommend the oil prepared by Dr. Short to the notice of our readers. We understand he imports the seeds, and prepares the oil himself; and from our own knowledge we can declare it to be perfectly free from adulteration, and, consequently, entitled to the highest confidence.

---

*The Edinburgh Medical and Surgical Journal.* October, 1830. Edinburgh, Adam Black. pp. 442.

We have just perused the present Number of this periodical, and, in justice to Dr. J. C. Gregory, we feel bound to admit that it has raised him considerably in our estimation, inasmuch as, *inter alius*, it contains two infinitely more stupid papers than his memorable attempt on the reputation of the stethoscope, which we alluded to on a recent occasion. We shall dispose of these, before we notice the very few articles which deserve our approbation. The first is an elaborate inquiry by Dr. John Davy, Physician to the Forces, corresponding member of a hundred societies, &c.—“Whether the putrefaction of animal matter is attended with an elevation of temperature?” On this most important and disputed topic, Dr. Davy favours us with twenty-six pages of observations and experiments, and at length ends in a conclusion, in which it may be truly said, that “nothing is concluded;” for after involving himself and his readers in innumerable perplexities, after submitting every fluid and solid, whether simple or compound, in the animal body, to the operation of ill-devised and apparently worse-executed experiments, he seems to find out, that heat may actually be generated by animal putrefaction; an opinion which he propounds with as much philosophical *naïveté*, as if the worthy author, or his readers, had never seen or heard of, a hot-bed or a dunghill. The next of these very

original communications, is a *second-hand* document of most ample dimensions, by Dr. Carswell, on the chemical perforation of the stomach, and which has already appeared in French in the *Journal Hebdomadaire*; it consists, in the first place, of a minute recapitulation of the various opinions held by all the authors who have ever written on this occurrence, and in the next, of a few experiments on rabbits, repeated by the author himself, from which he draws the conclusion, that if one of these animals be killed suddenly while digesting food, the stomach and adjacent parts in contact with the gastric juice, are also liable to be digested; and, moreover, that their stomachs, when opened, emit a sour smell, and litmus paper becomes reddened when applied to the corroded parts. To elucidate and enforce this single inference, the author spins us twenty-nine pages, apparently careless, or ignorant of the fact, that for the last seven years there has not existed a medical jurist who was not entirely aware of the circumstances which he wastes so many words in narrating.

The Number, however, is by no means destitute of interesting matter; at any rate it contains two papers worthy of attentive perusal; one of them by Mr. Syme, of Edinburgh, on the quarterly progress of his new surgical hospital, and a second by Dr. William Stokes and Mr. Hart of Dublin, corroborative of Dr. Corrigan's new opinions on the motions of the heart; besides these, there is a memoir by Dr. Shortt, on the treatment of amaurosis by strychnine, which, though deprived in a great measure of the reputation of novelty by a scandalous forestalment, to which we shall again advert, still contains information of no ordinary practical value. Such are the leaders in the original department, and these, by a skilful editorial manœuvre, are disposed in the front and rear of the publication, the main body being filled up with all sorts and sizes of materials. Thus Art. 6 is pompously styled, “Contributions to Pathology and Practice of Physic,” by Drs. Henderson, Messrs. Graham, Lawrence, Ranken, and Bodkin, separate cases from Chelsea, and Wick, Ayrshire, and Tuam, and, luckily for the editor, sent just in the nick of time to fill up space, and save the necessity of making another extract from the *Jour. Hebdomadaire*.

We shall now proceed to the consideration of the three papers referred to in the preceding remarks. Of Mr. Syme's quarterly report, we again feel called on to speak in terms of the warmest approbation. We quote, beneath, Mr. Syme's brief statement of the sources whence the expenditure of the establishment was supplied, and to this we would request the special attention of our readers. Let them contrast this record of benevolence with the sordid and selfish gripings of many of our hospital surgeons, who, possessed of treble the income of Mr. Syme, refuse even a sufficient portion of their time to the necessities of their patients; again let them place the manner in which Mr. Syme courts the scrutiny of the public on his treatment of diseases, in juxtaposition with the mystery with which his brethren would veil their proceedings, and then let them deny, if they can, that there is a necessity for reform in the administration of our hospital affairs. We feel great pleasure in noticing the just compliment paid to Mr. Syme by the Edinburgh College of Surgeons, which is modestly alluded to in the following extract:—

"In commencing this report, I have great pleasure in stating that the College of Surgeons of Edinburgh now recognise, not only the clinical lectures, but also the attendance on the Surgical Hospital, as qualifications for their diploma.

"I may take this opportunity of explaining the sources from which were derived the 800*l.* that appeared in last report as paid by me to the support of the institution.

Fees of students attending my clinical lectures .....	£ 400
Board of two house-surgeons for six months, and one ditto for twelve months .....	200
Surplus of expenditure required from myself .....	200

£ 800

"Since last report, 545 cases of surgical disease have been presented for relief. Of these 82 have been admitted into the house."

Nearly the entire of this report is occupied by various diseases of the joints; we select some interesting notices relative to Mr. Syme's recent practice in the excision of the elbow-joint:—

"Elizabeth Johnston, ætat. 16, from Falkirk. In the first of these reports I

mentioned the case of this girl, who entered the hospital last summer on account of a diseased elbow-joint, which exhibited the most formidable appearance of any that I have yet met with, but which, nevertheless, was completely cured by the operation of excision. She returned home, and remained perfectly well, using the arm for all ordinary purposes until December last, when, after exerting herself too much, her wrist swelled and became painful. Tartar-emetic ointment was applied, and afterwards blisters; but an abscess soon formed, which opened, and has continued to discharge ever since. A probe introduced into the sinus, which is situated over the lower end of the radius, enters a large carious cavity of the bone, and can be pushed downwards into the wrist-joint.

"As amputation appeared the only resource, it was performed on the 24th of June above the elbow, by the method of double flap. She recovered most favourably, and is now well.

"The elbow being dissected, afforded a specimen of the union which is established between the bones in such cases. When the integuments and muscles were dissected off, the appearance presented was wonderfully little different from that of a natural joint, owing to a great mass of fibrous ligamentous-looking substance which connected the bones together. This connecting medium, which was above an inch in length, and perfectly flexible, did not constitute anything analogous to an ordinary articulation, and more resembled the structure that usually exists in the false joints that result from fracture of the bones. My friend and pupil, Mr. Charles Bell, made a sketch of the preparation, which gives a very good idea of its appearance, and which, therefore, I have caused to be engraved to illustrate this description.

"The unfortunate occurrence of disease in the wrist after that of the elbow had been removed, certainly affords no objection to the operation of excision. In one of these reports I mentioned the case of an old woman whose hand I removed on account of caries of the wrist, and who afterwards required amputation of the arm for disease of the elbow-joint. No one, I suppose, would consider that case any objection to the operation of amputation.—In the last number of this journal, Dr. Christison has stated that, from what I have seen of excision of the knee-joint, I am not inclined to practise or recommend it any more than M. Roux, who also thought it right to satisfy himself as to the advantages of the operation in regard to this joint by actual trial. But in the diseases of the shoulder and elbow-joints requiring removal there cannot be a doubt that the introduction of excision in-

stead of amputation is a very great improvement. Most of the patients on whom I have operated now use their arms for all the purposes, and with the same facility, as formerly. It has seemed surprising, that in the course of eighteen months I should have had occasion to perform the excision of ten elbow-joints. To account for this, it will be sufficient to recapitulate the places from which the patients came.

"Edinburgh, 3; Aberdeen, 1; Lanark, 1; Falkirk, 1; Auchtermuchty, 1; Arbroath, 1; Cupar, 1; Perth, 1.—Total, 10.

"Janet Burns, *ætat.* 26, from Lanark, was admitted on the 23d of June, on account of a flat fluctuating tumour, about the size of the palm of the hand, on the inner side of her right knee between the patella and condyle of the femur. It had existed for several years, and was increasing. It gave her no particular uneasiness, except apprehension as to its consequences.

"This patient was one of the first cases in which I cut out the elbow-joint, and was a very unpromising one, as may be seen from the account I have given of it in the first of these Reports. The cure is nevertheless so complete, that she can use the arm (the right one) for sewing or knitting the whole day long, and when she was adjusting her dress, or arranging the applications to her knee, it was difficult for a stranger to decide which arm had been the subject of operation. I have repeatedly seen mistakes committed in doing so.

"I may here remark, that a girl who came from Auchtermuchty, to have a small encysted tumour removed from her cheek, stated that her brother, James Page, who had his elbow-joint removed last spring, (see Quarterly Report for February 1830), now uses both arms equally; thus, for going to the well for water he carries a pitcher in each hand, and that when he requires only one hand, he uses the arm operated upon, as it is the right one."

Dr. Shortt's paper on the treatment of amaurosis by strychnine, is an interesting practical detail of the results of this peculiar treatment, of which he, it appears, was the first to make trial. As we before noticed, the effect of his memoir has been not a little diminished by the greater part of its substance having already appeared in print (the meanness of the act will sufficiently demonstrate where) through the low and impertinent officiousness of an empty understrapper connected with the Royal Infirmary. Scarcely had Dr. Shortt set his train of experiments in motion, before, with their anticipated conclusions, they were

hurried to the press, without the sanction or knowledge of their deviser. Such contemptible interference is, it is true, almost beneath reprobation, but it is really too bad, that the merits of a skilful and scientific man are to be filched from him by such a medical puppet as figures on this occasion. Of these cases Dr. Shortt now furnishes us with an ample and satisfactory detail. He asserts his belief, that the Endermic method of treating amaurosis by strychnine is only efficacious when the disease depends on functional paralysis of the nervous apparatus of vision, but that in this form it is a method of unquestionable power. The success of the treatment is rendered not the less valuable, that in all his cases the application of the strychnine gave rise to no serious constitutional disturbance, as might have been apprehended in consequence of the terribly virulent effect that poison is capable of exerting under appropriate circumstances. It will, besides, be noticed, in the case we select for the illustration of Dr. Shortt's practice, that blisters had already been applied without effect, so that the cure cannot be referred, as some have imagined, to the counter-irritation which they by themselves would have produced.

"CASE IK.—Janet Barclay, *ætat.* 28, admitted June 18th, 1830. Two years ago symptoms of incipient amaurosis commenced in her right eye. These continued gradually increasing till a few months ago, since which time the amaurosis has been almost perfect, a small portion only of the retina retaining its sensibility, so that at the distance of six inches from the eye, the sphere of vision does not exceed a circle of half an inch in diameter, and in that small space sight is very imperfect, from a constant appearance of *muscæ volitantes*.

"The left eye became similarly affected, but in a much less degree, three months ago. In it the *visus reticulatus* is now very perfect, rendering her unable to see objects distinctly at a very short distance, or to read the largest print.

"The pupils are moderately dilated, and slightly sensible to light. The posterior part of both eyes seems somewhat opaque. The amaurosis, at its commencement in the right eye, was accompanied with deep-seated pain in the eyeball, which, after a short time, disappeared, but recurred when the left eye became affected, and has continued more or less since. Bowels irregular; other functions natural. Blisters have been applied to her temples and nape of

neck, without effecting any improvement in the vision.

"The application of extract of belladonna to the eyebrows produced its usual effects. The system was affected slightly by mercury, and purgatives administered without any beneficial effect. Blisters were then applied to her temples, and one grain of strychnine sprinkled on their surfaces. This application was continued till it occasioned considerable vertigo, headach, tremours, &c. Vision rapidly improved under the above treatment, which was at different times repeated with the same success, so that on July 26th, the sphere of vision in the right eye was restored to almost its natural size, and the appearance of *muscæ volitantes* removed. The *visus reticulatus* in the left eye had likewise almost completely disappeared. Had no pain in the eyeballs, or headach, and she was dismissed cured."

Notwithstanding the apparent safety of this application, we still think that Dr. Shortt has underrated its dangers. There are many poisons, it is well known, which act with much more deadly energy when applied to a bleeding surface, than when taken into the stomach or great intestines. This has been especially noticed with regard to wounds of instruments poisoned by the juices of the *Upas anliar*, and other plants closely allied to the *Strychnos nuxvomica*, from which the strychnine is obtained; even in Dr. Shortt's cases some approach to their peculiar effects was observed, though never, as we before observed, amounting to serious or alarming indications. On this point we do not think Dr. Shortt has sufficiently dwelt, and we therefore think it necessary to advise such practitioners as would imitate his treatment, to be especially cautious never to apply the strychnine but to a suppurating surface, and to disturb the granulations as little as possible while renewing their dressings.

In conclusion, we have to notice another *coincident* corroboration of Dr. Corrigan's opinions, namely, the brief memoir of Dr. William Stokes and Mr. Hart on this subject. It appears that about the same time that Dr. Corrigan remarked the non-synchronism of pulse and impulse, that Dr. Wm. Stokes made the same observation, and, assisted by Mr. Hart, submitted the matter to experimental investigation. The result of this inquiry was, that, without any knowledge of Dr. Corrigan's opinions, they sent their conclusions to the "blue journal" for publication,

which conclusions we subjoin, and which were just in time to be committed to press. Just as the whole impression was struck off, Dr. Corrigan's paper appeared, and Messrs. Stokes and Hart immediately wrote to the editors, requesting the suppression of their article; but this being, under the circumstances, utterly impossible, the memoir now stands an almost irresistible proof of the truth of Dr. Corrigan's views on this important subject. We present our readers with the conclusions of these gentlemen in their own words:—

"1st. That in a state of health the impulse of the heart precedes that of the arteries.

"2d. That the interval between the impulse of the heart and the pulse in the arteries is in the direct ratio of the distance of the vessels from the centre of the circulation. Thus the interval between the impulse of the heart and that of the arteries in *innomina* is often so slight as to be scarcely perceptible; the pulse of the carotid presents a longer interval, and so on with the rest.

"3d. The pulsations of arteries in different parts of the body, but at equal distances from the heart, are synchronous. Thus between the pulsations of the femoral and the radial artery, as felt at the wrist, no difference could be observed.

"4th. The greater the distance the longer will be the interval; thus the pulsations of the radial artery always precede those of the tibial.

"5th. That, although the actual pulsations depend on the systole of the left ventricle, yet the diastole of the vessels does not occur synchronously in all parts of the body, but is progressive.

"All these observations are most easily made on a healthy adult subject, whose heart is acting slowly, but at the same time strongly."

We congratulate Dr. Corrigan sincerely on the corroboration thus afforded to his talented, original, and deeply-interesting opinions. Dr. W. Stokes is known to be the most accomplished stethoscopist in Britain, and Mr. Hart's reputation as an anatomist and experimentalist, is also entirely unrivalled. To us further confirmation appears totally superfluous, and we shall accordingly, in a subsequent number, devote a sufficient portion of our pages to the consideration of the new diagnostic and pathological data which Dr. Corrigan's researches have thus supplied.

## ST. BARTHOLOMEW'S HOSPITAL.

## LEPRA VULGARIS.

THOMAS MARIGOLD, ætat. 21, admitted into — Ward under Mr. Vincent, 25th of September, 1830.

The scalp, trunk, and extremities, are thickly covered with a scaly eruption, varying in intensity in different situations on the thorax, loins, and flexures of the great joints; it forms one general uninterrupted coating of a deep-red colour, and sprinkled with small whitish scales; the skin is stiff and wrinkled, and from its dryness, causes considerable uneasiness on the motion of the respiratory muscles. On the thigh and arms the spots are more distinct, strictly circular, varying in size from a quarter of an inch to an inch in diameter; in some places the spots are entirely covered with scales; in others, in which partial desquamation has taken place, the margins alone are scaly, and the centres of a deep-red colour.

He states that the disease is of sixteen years' duration, and appeared at first in the form of minute scales of the scalp, and spots over the trunk and extremities; since then the eruption has progressively increased, and though occasionally rather less in quantity, has never for any period been entirely absent. He has been, before admission, subjected to various plans of treatment without relief, especially to a course of the liquor arsenicalis about twelve months, since which he thinks the disease has been rather aggravated.

His previous health has been good, and his functions are generally well performed, but his bowels are habitually costive; his tongue on admission was foul but moist; skin natural; and he states that sweating is readily induced by exercise or warmth. His grandfather, father, and brothers, have all been affected in the same way. There is no evidence of any syphilitic contamination.

Since admission he has been treated with mercurials and the warm-bath, but as yet no improvement has taken place; on the contrary the eruption appears, Sept. 30, rather increased, and no additional desquamation has taken place.

October 6. Some tenderness of the gums; no change of symptoms.

"*Habt. pil. hydr.*, gr. v, mane et vespere descendatim balneum tep." To have soda water and milk diet.

## WESTMINSTER HOSPITAL.

## FATAL CASE OF ERYSIPELAS IN A DEBILITATED SUBJECT.

FRANCIS WARREN, ætat. 27, admitted March 31, 1830, a gentleman's valet, has

lived rather freely, but has generally had good health. During the wet weather, some weeks back, he got his feet very wet, but felt no inconvenience until about seven days ago, when his throat became sore, which occasioned difficulty in swallowing. On Sunday evening (March 29th) he observed his throat much swelled externally, just under the base of the lower jaw at the right side; the next morning he felt exceedingly unwell, and he was obliged to keep his bed; in the afternoon he found his right ear red and swollen, and suffered a burning pain in the part; the redness gradually spread over the right side of the face and some part of the neck.

On his admission, the right side of the face and nose were uniformly of a dingy-red colour; the redness extended about half way down the neck; the pain he suffered was of a pungent kind; the parts were much swelled, especially beneath the base of the right side of the lower jaw; the ear was vesicated. He complains of difficulty of swallowing, but has no headach, or any other mark of increased action in the brain; surface of the body heated; pulse 110, soft and oppressed; tongue much furred; his bowels had been freely opened by jalap, which he took of his own accord. The patient was seen by Mr. Guthrie in the morning; was ordered to take antim. tartar. gr. vi, pulv. ipecac. ʒj, immediately, and afterwards calomel, gr. x, to act freely on the bowels, and to follow it with a mixture of liq. ammon. acetatis. Dr. Roe saw him afterwards, and the man was taken in under the physician's care. Dr. Roe ordered hirudines no. xii, faucibus externis, warm-bath fomentations, and hydr. submur. gr. v, pulv. jalap gr. x. He was not put into the bath on account of the depression which he manifested.

10 P.M. The redness of the face less; swelling somewhat reduced, but the inflammation had extended further on the neck to the left side; pulse weaker than it was in the morning.

April 1. He is this morning very low; pulse 120, and feeble; vomits frequently, and answers questions in a low tone of voice. The redness, which is of a paler hue, now occupies the ear, the whole of the right side of the face and neck, extending to the left side, and also to the breast; the surface is not vesicated. He passed a very restless night, talked incoherently, and was purged by the powder. Ordered, by Mr. Edwards, a tablespoonful of brandy occasionally, and to take the following:—

*Conf. aromat.* ʒii;

*Sp. amm. aromat.* ʒiv;

*Decoct. cinchon.* ʒi, ʒi 4tis horis.

The inflamed surface to be powdered with flour.

10 P.M. Pulse 140; excessively feeble; has great difficulty of swallowing; the neck more swollen.

*App. emp. lyttæ callo.*

Continue the brandy.

April 2. Has passed a bad night; he took his brandy regularly during the night, which he says composed him for a time; the parts are not so much swelled, nor so red; complains of great soreness of his throat and inability to swallow; voice scarcely audible; there is a great discharge of muco-purulent matter from the eyes and nose; pupils dilated; tongue dry, chopped, and brown pulse 126; has more fever; vomiting somewhat subsided; bowels not opened since yesterday morning.

*Cap. hydr. submur. gr. v;*

*Pulv. rhei, gr. xv, statim.*

Four P.M. The powder opened the bowels freely; surface of the body much heated; pulse has risen; it is now firm and fuller, beating about 100 in a minute; complains of not being able to swallow, from the great collection of mucus in the throat; external inflammation diminished. Omit the brandy. Continue medicamenta.

*Gargarisma ex liq. potass. liq. ammon. aa ʒii. Aqua thi.*

10 P.M. Not so well; pulse 120, and very feeble; surface cool; countenance anxious, and he talks incoherently.

April 3, 10 A.M. The nurse states he was very restless all night, was affected with delirium, and she could not get him to take his medicine. The external inflammation has quite disappeared without vesication; internal fauces more affected; is delirious at times; the patient is more debilitated; pulse 130, very feeble; bowels not open since yesterday evening.

*Appl. emp. lyttæ nuch. Hydr. submur., gr. x, statim.*

Apply fomentation to the face, in order to restore the superficial inflammation.

Two A.M. Ordered by the physician to discontinue all the remedies hitherto exhibited, and to be immersed immediately in a warm bath, and to take the following:

*Decoct. aloes, ʒss, o. h. donec, alvus respond.*

*Ammon. carbon. ʒi;*

*Aq. menth. pip., ʒvi. M. ft. haust.*

*Cujus cap. ʒss, 4tis horis.*

*Enema commun. injic. stat.*

The warm bath was not used, and Dr. Roe ordered it to be postponed until seven P.M. At that time the patient was in a state of great depression; pulse frequent and weak; surface of the body cold, especially at the extremities. When the ammonia draught was administered, the patient was almost thrown into convulsions, by the suffering which the attempt at swallowing so

strong a stimulant excited; the power of deglutition, however, was previously so much impaired, that he was incapable of swallowing, without great difficulty, even the aloetic draught. The ammonia mixture was now diluted, and the patient succeeded in swallowing a little, but this produced so much disturbance that it could not be repeated.

As the patient's vital force was rapidly ebbing, it became necessary to apply stimuli of some sort, and the apothecary accordingly had brandy administered in arrow-root, and fomentations assiduously applied to the part; the patient's difficulty of deglutition, however, prevented any great quantity of brandy being given. A great quantity of black fetid matter was ejected from the bowels.

Nine P.M. Dr. Roe visited the patient; the brandy to be continued, as well as the fomentation.

Ten P.M. The superficial inflammation appearing to decrease, the surface was covered with mustard plaster, which remained on for some time. Fomentations were afterwards resumed, and the patient was well covered up with blankets, and an injection of brandy, laudanum, and tinct. assafoetid. with gruel, was thrown up the rectum, but not retained.

The patient was persuaded to take ʒiss of the liq. op. sedativ. or lump-sugar, and it is supposed the greater part of it found its way into the stomach; the surface, however, was still cold, and the patient offered the most violent resistance to every attempt at giving stimulants, in consequence of the pain the act of swallowing excited. These applications were continued from ten till two o'clock A.M. At this time Mr. E. introduced, with some difficulty, a gum-elastic tube into the œsophagus, and injected by this means ʒvj of brandy, mixed with hot water; qualified with sugar and spices. The temperature of the patient at this time was a little augmented, but the pulse unimproved. In consequence of the restlessness of the patient, a difficulty was experienced in making the fomentation efficient, and about twelve o'clock a large poultice was applied over the whole inflamed surface of the head and face.

Two o'clock A.M. The patient evinced a disposition to rest, which was attributed to the effect of the opium, and he was consequently left, with appropriate directions, to the care of the nurse. He afterwards continued in a quiet state, and no change was evident to the nurse until near seven in the morning, when he expired without a struggle.

The patient had formerly suffered a good deal from syphilis, both in its primary and secondary stages, and had been in the habit, up to the moment of his admission into the

house, of taking daily quantities of opium. The post-mortem examination exhibited a highly-diseased state of the larynx, especially at its upper parts, the natural characters of the glottis, epiglottis, and chordæ vocales, being nearly obliterated. A high state of inflammation existed in the pharynx and internal fauces.

### ROYAL WESTERN OPHTHALMIC HOSPITAL.

#### GONORRHOEAL OPHTHALMIA.

JAMES HALE, ætat. 21, living at No. 2, Kendal's Mews, George Street, Portman Square, was admitted Thursday, April 1st, having gonorrhœal ophthalmia. Contracted gonorrhœa three weeks since, and has suffered from ardor urinæ and discharge from the urethra for about fourteen days. Has taken balsam of copaiba, and lost the running and other symptoms on Friday last. On the Saturday, and the early part of Sunday, he considered himself quite well, but towards the evening he suffered from slight irritation at the inner corner of the right eye, but was entirely free from pain till the Monday evening; he then complained of a burning pain in the eye, suffered some inconvenience from light, and perceived the upper lid to be swollen. This continued to increase during the night, and on the following morning was attended with a copious clear discharge. During the day the pain and swelling increased, and towards evening the discharge became thicker. He passed a bad night, suffering from great pain; was gradually becoming worse on the Wednesday, and presented himself this morning for relief. There is considerable swelling of both lids, especially the upper one; great inflammation of the conjunctiva and chemosis, so that the cornea appears quite depressed, but it is perfectly clear, and the pupil is regular. Complains of increase of pain in the eyelids and eye towards evening, or on exposure to light; sight of this eye very dim. He has had gonorrhœa before, without any affection of the eye; is not aware of having transferred any of the morbid matter from the urethra to the eye. Had three leeches applied last night, but without any relief. His pulse is regular, tongue slightly furred, bowels confined.

A large quantity of the fresh-made, or strongest, nitrate of silver ointment was applied to the eye by Mr. Guthrie, and the lids then gently rubbed, so that it might be diffused equally over the conjunctiva. He was then cupped on the temple to twenty ounces, and ordered to foment the eye constantly.

*Hydr. subm.*, gr. v. h. s.

*Pulv. jalap.*, c. ʒi. mane.

April 2. The ointment caused considerable pain in the head and eye, which was, however, entirely removed by the cupping. Passed a good night; suffers no pain now in the head, and but little in the eye; Bowels well acted on by the medicine; tumefaction of the lids greatly reduced; chemosis less, cornea clear, pupil regular; discharge continues, and is of a thicker character; on the whole, great improvement. The application of the ointment was repeated in moderate quantity at twelve o'clock.

3. Was very easy last night, and free from pain; can open the eyelids himself, and see a little with the eye; the chemosis is less, but the cornea not so transparent as it ought to be, and the iris is slightly affected; has no pain in the brow; discharge still great. The ointment repeated; to be well purged, and cupped to twelve ounces in the evening.

4. Slept well, and had not any pain in the night; discharge less; can open the eye better, the upper lid being much less swelled; less chemosis; cornea shows signs of commencing ulceration in the centre. Says that he feels greatly better in every way. Ointment applied, and twelve ounces of blood taken from the temple.

#### *Haust. aper.*

5. Better in every respect. The ointment and purgative medicines repeated.

6. Has passed a good night; less pain and uneasiness; can now open the eye easily; ulceration has ceased to spread; chemosis whiter and diminished; cornea more transparent; discharge very much diminished; pupil dilated; iris a little discoloured.

#### *Rep. unguentum;*

*Cupiat hydr. submur.*, gr. ij. *sextis horis;*  
*Ung. hydrar.*, ʒss, *illin. fronti o. n.*

7. Feels better, and is so in every respect; the ulcer is flat and broad, but not deep, and is slightly opaque. To continue all the medicines.

8. Ulcer presents the same appearance, with the exception of slight increase of opacity; bowels open; mouth unaffected; complains of slight superficial pain.

#### *Rep. med. et ung.*

9. Has had a good night; is entirely free from pain, and the discharge has ceased. Pupil natural; iris discoloured, and acts sluggishly; ulcer appears rather deeper, and there is some increase of redness at the lower part of the conjunctiva; mouth rather sore; slight salivation.

#### *Omitt. pil.*

#### *Rep. ung. arg. nitr.*

10. Slept well last night, and is quite free from pain; pupil rather dilated; iris natural; ulcer has not spread; the inflammation of the conjunctiva and chemosis much the same as yesterday. Says that his eye

feels easier to-day than since his admission. Mouth still sore.

*C. c. ad 3xij.*

*Pulv. jalap. c. 3i, statim sumen.*

*Omitte alia.*

11. Slight discharge of cold water from the eye, but no purulent matter; ulcer in the cornea is in the same state.

*Ung. arg. nitr.*

12. *Empl. canth. nucha.*

13. No pain; sight very little impaired.

*Lotio aluminis.*

14. Improving.

*Ung. arg. nitr.*

*Pulv. jalap., c. 3i.*

15. Free from pain; no discharge; inflammation of the conjunctiva disappearing; ulcer healing.

*Gutt. arg. nitr., gr. iv ad 3i.*

16. *Ung. arg. nitr.*

27. The nitrate-of-silver ointment has been repeated regularly every other day since the last date, and he is now well enough to return to his occupations. The slightest possible opacity only remains where the ulcer of the cornea was, and that does not in the least interfere with his sight.—*Med. and Phys. Jour.*

## BOROUGH SCHOOLS.

THE whole machinery of lecturing, demonstrating, and "walking round," is in motion in the Borough. For whose advantage the wheels will chiefly work, whether mostly for that of the teachers, the pupils, or the patients, the end of the session will best show.

The introductory lectures were well attended by the new pupils, who are gradually settling themselves according to their tastes. Mr. Grainger has a good class, and has engaged a new demonstrator, who was much wanted last season, and who appears to possess the talent and industry necessary for the office. Dr. Gordon Smith read an introductory lecture on medical jurisprudence on Monday evening, which was listened to with great attention.

On Tuesday Mr. Key operated on two boys, aged, each of them, about thirteen years. The first case was attended with some difficulties. The operator employed the straight staff, and made the incisions as usual. A gush of urine followed the incision into the bladder. After repeated attempts to extract the stone, a small portion was broken off, in consequence, as Mr. Key said, of his inability to seize the stone beyond its axis, from the strong contraction of the bladder. A little warm water, however, having been injected, the operator succeeded in extracting the whole calculus, which

was of the mulberry kind, and of irregular shape. The operation in the second case was performed with great celerity and adroitness; very little more than a minute was occupied from the first incision. The urchin made a very great outcry at the commencement of this terrible operation, but in a few seconds recovered sufficiently from the agony into which the process had thrown him, to exclaim, "b— — your eyes, make haste."

Mr. B. Cooper, on the same morning, performed the operation for popliteal aneurism on a man *ætat. circiter 35*, in a cool and careful manner. The pulsation in the tumour ceased immediately on the application of the ligature.

It is impossible to regard the crowded state of the floor of the theatre during operations, without regret. With so many gentlemen at the elbow of the surgeon, the pupils have not the least chance of seeing the various steps of the different operations.

Mr. Morgan has this season adopted the plan of placing the name of the disease above the bed of each of his patients.

## HOPITAL DE LA CHARITE.

### STAPHYLOBAPHE, FOLLOWED BY DEATH.

A YOUNG girl, who had from birth been affected with divided palate, was, on the 28th of August, operated on by M. Roux. On the evening she was suddenly seized with a violent pain in the throat, with cough, and all the symptoms of violent pneumonia, which proved fatal on the eighth day. The post-mortem examination was unfortunately opposed by the parents; and it is accordingly doubtful whether the case was one of bronchitis or pneumonia. M. Roux, however, candidly admits, that the operation is to be considered as the cause of the fatal result. He has performed the operation fifty-one times, with various success, but never lost a patient before. In one case, where the operation was twice performed during six months, bronchitis came on after each operation, and thus hindered its success; the inflammatory affection was, however, subdued.—*Lan. Franç.*

## LONDON HOSPITAL.

MR. HEADINGTON AND SIR WM. BLIZARD.

To the Editor of THE LANCET.

SIR,—As pupils of Mr. Headington, we think an apology quite needless for the intrusion of a few remarks in your publica-

tion, relative to the foul and malicious letter signed W. A. Walford, which appeared in *THE LANCET* of the 25th of September. We distinctly notice the term "degradation" applied to our worthy and upright teacher, Mr. Headington, and would ask the author of the base aspersion, in what way and manner that gentleman has degraded himself. Is it because he differs in opinion from W. A. Walford, and stands opposed to a medical gentleman as coroner? We flatter ourselves, that Mr. W. A. Walford's ignoble soul can find no other cause for the asperity of language contained in almost every line of his letter. We would tell Mr. W. A. Walford, that in this age of liberty, no man has a right to defame the character of another, merely because he holds a different opinion, and that the attack on Mr. Headington proves the author's mind at once pitiful and mean, and deserving the utmost contempt. Though pupils of Mr. Headington, we are not ashamed to acknowledge publicly, that had we possessed a voice at the late election, it would have been in favour of a medical coroner; and although this difference of opinion may exist between the worthy surgeon and ourselves, yet we feel a pride in being under the tuition of such a master. We cannot refrain from noticing at the same time the hostile feeling expressed by Mr. W. A. Walford towards the venerable Sir Wm. Blizard, and in reply to this part of his letter, we would sincerely wish that every member of our profession may possess at the advanced age of ninety-two years the same soundness of mind and intellect still developed in Sir William's character, proving,

"If such the eve, how great the morn has been."

London Hospital, Sept. 27th, 1830.

QUACKERY.—"In the year 1782, that extraordinary empiric of modern days, Dr. Graham, appeared in London. Among the furniture of Dr. Graham's temple 'was a celestial bed, which, he pretended, wrought miraculous effects on those who reposed in it; he demanded for its use during one night, one hundred pounds, and such is the folly of wealth that several personages of high rank acceded to his terms.'"—*Hone's Table Book*.

## TO CORRESPONDENTS.

We cannot advise *A Gentleman* whose letter is dated from Southampton, to place his child under the care of the gentleman to whom he has referred. We know nothing of his talents, but his habits seem to be rather quackish.

If Mr. J. M. Walker of South Shields will get his drawing executed with more care, we shall be happy to insert a sketch from it. The foot should be fore-shortened. It ought to be copied by an artist.

*A West-end Student*. Certainly. Mr. KING held the office of house-surgeon in the Hotel Dieu, and he is particularly well qualified for teaching the principles and practice of surgery.

*Delta*, of Alnwick. Reply to question first,—Yes. Second question,—Two winter sessions of six months each. Third question,—With the exceptions he mentions, not less than 130l.

If *W. W.*, on his arrival in London, will call at *THE LANCET* Office, 210, Strand, he shall receive the fullest information on the subjects mentioned in his letter dated Sept. 10th.

## BOOKS FOR REVIEW.

*A Practical Treatise on the Diseases of the Eye*. By WILLIAM MACKENZIE, Lecturer on the Eye in the Univer. of Glasgow, and one of the Surgeons to the Glasgow Infirmary. London, Longman. 1830. 8vo. pp. 861.

*A Demonstration of the Nerves of the Human Body, consisting of Four Parts; Part I. The cervical and thoracic portions of the sympathetic, and the nerves of the thoracic viscera; Part II. The lumbar and sacral portions of the sympathetic and the nerves of the abdominal viscera; Part III. The cerebral nerves; Part IV. The spinal nerves*. By JOSEPH SWAN. Part I. Price two guineas. London, Longman and Co. Imperial folio. Eight Plates.

[1830-31.]

## INTRODUCTORY LECTURE

ON

## MEDICAL JURISPRUDENCE.

DELIVERED AT

*The Theatre in Webb Street, Tuesday,  
October 5th.*

By JOHN GORDON SMITH, M.D. &c.

I AM of opinion, that the object of an introductory lecture is frequently misunderstood, not only on the part of the audience, but on that, likewise, of the author. It is wrong to expect, and still more to attempt, the communication of details; and it is advisable to avoid, if possible, the illustration of particular points; for the attention should be directed to general and comprehensive views of the utility and importance of the study upon which the parties are about to enter. It is my impression, therefore, that we shall do better upon the present occasion, by indulging even in something of an excursive nature, than if I were to offer a formal and systematic account of the business which will come before us hereafter. That I purpose to enter upon while the class is forming, and, in the execution of such an attempt, to submit (at our next meeting) an outline of the topics which it will be our duty to investigate, as well as of the order in which it is my design to bring them forward.

GENTLEMEN,—It is but a short time since one of the most distinguished members of our legislative body asked me, what was meant by MEDICAL JURISPRUDENCE? Were such a question to be put now, one might, with tolerable safety (though certainly not with perfect politeness) refer the inquirer to the bill-stickers of London and Middlesex. To some in my situation, it might appear to be a dream, or merely a picture drawn in the imagination—that a branch of medical study, unrecognised by any of the medical authorities in this kingdom,

should have raised such a ferment in society as we have just seen it do; should have roused the attention of men of all classes; should have caused the assembling of 50,000 sensible and well-conducted persons, for no other purpose than to listen with eagerness to one of our profession, while he described the nature, the vital importance, even I may say, the *political* importance of *medical jurisprudence*; should have induced the expenditure of 10,000*l.* or 12,000*l.*, and led to a trial of intellectual strength and moral influence, between the mighty profession of the law, and the modest pretensions of the sons of *Æsculapius*. Yes, gentlemen, all this, and much more than this, has been already accomplished, and there is yet more to be done in pursuit of the particular object, concerning which there may have occurred a difficulty, but it is almost unnecessary to inform you, that there has been no defeat. I have said that all this might, to some standing in a situation similar to that which I now occupy, appear to be a vision, an unreal thing; but I foresaw it long ago; and although many of my friends are ready to testify that my own expectation as to participating in the advantages had long been faint enough, they are able also to declare, that my language on the subject of others reaping where certainly it had been my task to sow, had all along been confident and convincing.

In the course of those unusual studies to which for many years my attention has been prominently directed, I began to discover what, while devoted to the ordinary duties of my profession, I had overlooked—that there were many and some very great anomalies in medicine. Perhaps my want of attention was chiefly, if not entirely, owing to the circumstance of my early professional life having been spent at a distance from the scene of those abuses, and under circumstances which precluded their encroachment where I was—I mean in the hospitals of the army. But I had not long returned to the pursuit of professional literature, and to habits of association with my professional brethren, before I observed some of these defects existing in a most glaring and preju-

H.

dicial manner—prejudicial even to the true interests of those in whom I thought they were even most conspicuous. More particular allusions it is not my intention at present to make; and you will consider it more interesting, as well as more pertinent to the occasion, if I go on to inform you that, as I made progress in this line of observation, I began to discover a sure and certain method of correcting every-thing, or, at least, of making medicine as perfect as any-thing human (if it be not more than human, which for one, I consider that it is), any-thing confided to human management is capable of becoming; and this I saw was to be done by MEDICAL JURISPRUDENCE. And now, gentlemen, *medical jurisprudence* is at work; it has done! it is still doing. It wanted but a station, and that station it has got. From that station all the powers of earth cannot now move it. Our force is mighty, and *shall* prevail.

Before going farther, let me tell those young friends, to form an intimate acquaintance with whom, by joining their respected teachers in the pleasing duty of pointing out their truest interests, and securing their future welfare, is the purpose of my coming here: let me endeavour to tell them of something that has been done for *them* within the few past months; and I shall introduce the subject by quoting the first paragraph of a letter I have recently received from one of the greatest, if not the greatest, of the philosophical physicians now adorning the profession. This gentleman expresses himself as follows:

“Sept. 28, 1830.

“My dear Sir,—On your account, as well as on account of the community at large, I rejoiced in the decision of the Apothecaries' Company respecting medical jurisprudence. It will, I am persuaded, give a new aspect to medical men when they appear before the public; and it will improve their reasoning powers, which certainly will give to them a new aspect at the bed-side.”

Such is the opinion of a great man, of a good man, of a celebrated physician, with whose name I would make you acquainted, but for the circumstance of the communication which contains this passage not being intended to meet the public ear. If, however, I know any-thing of him, I know this, that he would not refuse the sanction of his name, or the full exercise of his best services, were public benefit to be thereby promoted, or professional respectability enhanced.

And what, it may now be asked, is this advantage which, within a few months, has been reaped by the young members of, or aspirants to, the profession? Why, gentlemen, some of your anxious and industrious seniors have done more in the course

of that brief space to render your prospects, as medical men, inviting, than has been achieved since the revival at least of letters, and the admission of physic to the level of a scientific and liberal pursuit. We are no longer behind the clergy, and we have already taken our place by the side of the lawyers. It used to be divinity, law, and physic; it will soon be arranged in another manner; and, ere I die, I confidently expect to see our noble occupation standing at least as high in the estimation of the worthy, as the sacred functions of the priest. So was it among the dignified sages of antiquity; so was it with the Lord and Saviour of mankind—he went about doing good, preaching righteousness, calling all men to repentance and remission of sins, and exhibiting the sincerity of his designs, as well as the divine purity of his motives, by relieving suffering humanity—by *healing the sick*. These were his occupations; but we hear nothing of his countenance or co-operation with legal proceedings, or any sort of litigation. Property he declined the possession of; rights and privileges he never contended for; insults and injuries he not only endured with patience, but also forgave; and he wrought miracles,—brought down the celestial powers to the aid of sinful mortals in order to alleviate those distresses which were sometimes the consequence of their own misconduct. Such is, and ever has been, the true source of medical dignity; and they who lose sight of this splendid claim which our profession has over *almost* every other, must possess but an imperfect knowledge of the privileges and advantages to which they might and ought to aspire.

The duties of medical men have been hitherto performed in the secrecy of sick-chambers, or observed only in the wards of an hospital. It is hardly worth while (and shame be to us that it should be so) to quote the occasions upon which we have been exhibited to the public. There are passages in medical history, of which, for my own part, I should be glad were it possible to remain ignorant, and it has been to me a painful task to give them more publicity than others have been compelled to do; but painful as it has been to become acquainted with failures on the part of predecessors, and even of cotemporaries, I have gone through it with some degree of fortitude, because I was conscious that there was a remedy of easy application; and you are aware that no physician can apply a remedy until he has acquired a competent knowledge of the disease.

This reminds me that *medicine* is a word of more extensive signification than it has been hitherto usual to assign it. Its long-established meaning seems to have been restricted to the art of alleviating pain and

curing diseases ; but, even under this limitation, a contemplation of the constituents of medicine is almost beyond the reach of human intellect. The true physician is, in the opinion of all candid and enlightened men, the greatest benefactor to society, and the most respectable of the intellectual and cultivated orders. Clergymen have said so ; lawyers say it now ; poets and philosophers, to whose opinions the world has been accustomed most justly to defer, have sung or promulgated this praise, in expressing which there could never have been an interested motive, and which we do not accept as a compliment. You are all aware of the extensive scope of medical education, even under the restrictions just spoken of. I may, therefore, go over this ground in a speedy, and, comparatively, careless manner. None but the vilest quack can look society in the face, professing even the minimum of medical knowledge, unless he can exhibit some acquirements as a linguist and as a natural philosopher, besides a perfect acquaintance with the numerous sciences which more peculiarly belong to the medical art. When I speak of *medicine*, I desire it may be clearly understood that I make no distinction either between diseases occurring in particular parts of the body, or among those members of the profession who make a selection of the evils they are competent most successfully to remedy. We have, it is true, a division of labour among us ; some are called physicians, and others surgeons ; but the real physician is the man who can recognise disease in whatever shape it may appear, or in whatever part of the body it may be displayed. Let such a man be designated this or that, according to law, or be entitled to any step according to usage in the scale of precedence, such a one, if a good man, stands in the first rank of real worth and excellence.

Gentlemen, I am a friend to order, and I approve of distinctions in society. Anything of this nature which may belong to myself I am sufficiently proud of, and will not part with. After much up-hill work, I do not feel disposed to come down ; but if my position be one of eminence, I invite all rightly-disposed candidates for admission into the profession to come up and associate themselves with me. There is room enough, and to spare ; and allow me to add, that if the rising generation of medical men encounter degradation or grovel in the dust, the fault will be their own. The first duty of a medical student is to make himself thoroughly acquainted with the fundamental branches of education upon which medicine is built. As belonging to these I may specify *anatomy*, both human and comparative ; *physiology*, *chemistry*, *classical literature*, *natural philosophy*, and as many of what are

called *accomplishments* as he can acquire. Having laid this foundation, he will enter with advantage on the investigation of the nature of diseases, and find it an easy matter to form an acquaintance with remedies. He will even be delighted on discovering the facility with which he can do good by the practical experiments which he may safely undertake ; he will find that those very events which have established the imperishable fame of so many eminent men, are incessantly soliciting (if I may use the expression) *himself* to do as they have done to and fare as they have fared ; in short, there is no person whom I now address who has it not in his power to become the *Hippocrates*, the *Galen*, the *Hunter*, or even the very *Bacon* of his own day.

Such is a cursory reference to the constitution and character of the practising physician, a term under which I am anxious you should understand that I include all honourable members of the profession, whether they be designated doctors, surgeons, or apothecaries, according to law. The times in which we live are so much altered—so much improved—from those in which the greater part of laws and usages affecting medical interests were instituted, that these have become, in many instances, sources of irritation, and absolute impediments to utility. Such evils, however, must inevitably correct themselves, and some of them are even now in progress of correction.

The greatest improvement of recent date which I can quote, has emanated from a body which deserves the gratitude of every well-wisher to our order, and will receive the acknowledgments of many who do not belong to us. The Court of Examiners of the Company of Apothecaries (the only branch of the profession which possesses a legal power of directing what is to be attended to on the part of the medical student, in order to qualify him for practical duties), has added to the curriculum formerly prescribed to the candidates for their license, the branch which it has long been my object to teach. The importance of this to yourselves I have it not in my power to describe on the present occasion ; but it is evidently true that, if other bodies, which profess to have similar authority, do not follow this example, or, in other words, do not keep pace with their progress, the license from Apothecaries' Hall will signify that the proprietor is the best-educated member of his profession ; and the candidate will naturally hesitate about putting his friends to so great an expense as must be incurred for what, after all, will be nothing. What, indeed, is the state of the case now ? The *physician*, *par excellence*, so called—the doctor in medicine—considers the general and inter-

nal diseases of the body to be quite enough for him; and the *surgeon* keeps upon the outside, according to his own avowed pretensions, though neither of them can avoid crossing the path of the other; and it is impossible for any man to be either a good physician or a good surgeon, who has not an extensive knowledge of the duties of both. Then we have the accoucheur, who says that the uterine system, and its derangements, furnish enough for him to attend to. Others again confine themselves to the treatment of sore eyes; while a distinct class finds ample occupation in the management of the teeth. All this is honourable and advantageous, and the division of labour is one of the means of ensuring excellence. But besides these we have the *general practitioner*, the *apothecary*, who professes all this, and not only so, but performs it; and why? To speak the honest truth, because he is very competent to it, and because he *must*. London does not, and never will, contain more than a small proportion of the population of England and Wales, and in the country we seldom hear either of the physician or surgeon, while even in the metropolis they are seldom resorted to in the first instance. I am not, Gentlemen, prepared to go the length of saying, that such things are exactly as they *should* be—but *so they are*, and it is our duty to turn their state to the best advantage.

This I am convinced of, that the body of which I have just made, and ever shall, make honourable mention, is alive to the importance of their responsibility to the state, and of their duty towards you. Let me recommend to your careful consideration the remarks prefixed to their recently-promulgated regulations. These breathe a spirit worthy of upright men and medical philosophers, and upon one or two of them I cannot refrain from introducing an observation. They point, with expressions of disapprobation, to a system of teaching which has been a degrading characteristic of too many of the London medical schools; places which would never have gone by such a name, had not inexperienced youth been clapped into the measure of supporting them. The evil, now so decidedly condemned by the sentence of authority, is that of one man pretending to teach every thing! Who can be sufficient for this? For my own part I shall find enough to do in my own department, if I perform my duty in any degree even to my own satisfaction. It is impossible for students to acquire true qualifications, where the means of instruction are limited. I am, from honest conviction, formed after nearly thirty years' observation, decidedly hostile to these private undertakings in all branches of science, but most especially in medicine. They are, no

doubt, valuable as subordinates or auxiliaries; but they are dangerous to the last degree as prominent and reputedly sufficient seminaries for professional education. There is little *art* in teaching. The talent for imparting knowledge is, in great measure, a *gift* of nature; that gift, however, must be improved by assiduous application to fit the possessor for the peculiar business before him. In fact a man must be educated, or (what is the same thing, and indeed a better thing) must educate himself for this business. He must possess certain personal qualifications, or, at least, be free from certain personal defects in the first instance; and upon this favourable foundation he may, with great advantage and facility, raise a superstructure. But it may amuse *you*, while it illustrates this point, if I quote an observation made by a very learned friend of mine, and one who possesses, in a remarkable degree, the faculty of making every body comprehend clearly what he understands himself. We were conversing in a familiar manner upon the motives and pretensions of men in becoming lecturers, when my friend expressed himself to the following effect—"It is quite an infatuation. If a man be remarkable for a disagreeable exterior, an unmannerly and ungentelemanly deportment, if he labour under a gross defect or impediment in his speech, and most particularly if he do not understand the English language, or the very elements of elocution, he is sure to conceive the notion of becoming a lecturer." It may be said that it signifies comparatively little *how* a man imparts his knowledge, provided he possesses it. I am of a different opinion, and so are most of you. It is requisite that in those who undertake the duty of the teacher, whom the inexperienced alumnus naturally regards with a sort of reverential eye, should present, in almost every respect, a model for ethical imitation; and now, Gentlemen, I shall leave you in the possession of established professional acquirements, for the purpose of telling you something concerning an application of these, to which I must suppose that you are as yet strangers.

It is not my business to make, or to help to make, you anatomists, physiologists, or even physicians, in the enlarged and true sense of the word. All that is admirably provided for in the respective departments of those able men with whom I am associated. I am to point out to you the nature of certain public duties which, in your professional capacity, you will be often required to discharge. I am to make you, as far as I may be able, and you shall be willing, *medical jurists*; in order to become which, you must first be made *medical men*. I profess to qualify you for the honourable and impor-

tant task of vindicating the honour of the profession to which you are about to belong, before an observant world, and under the most critical circumstances; to show how it will be in your power to substantiate innocence, or direct the arm of justice where to fall upon the guilty; to enable you, on many occasions, to protect reputation and property, and to maintain the peace and happiness of society. This is a grand scheme, but far indeed from being an impracticable one. Often in the seclusion of my cheerless sick chamber, a place with which, in the middle of my preparations, it pleased Providence to render me painfully familiar, has the thought of what all this must lead to brought the tears into my eyes, and caused my heart so to palpitate, that I could not have uttered a word to my dearest friend. But that is, I trust, over; and our duty is to apply vigorously, steadily, and patiently, to what is before us, out of which I cannot myself tell what will come.

You are to be introduced to an acquaintance with medical jurisprudence, and more especially with that branch of it which we recognise under the title of forensic medicine. Medical jurisprudence is not the most eligible name by which the science at large ought to be known; I should prefer calling it state, political, or public, medicine; but there is no occasion to be captious on this point. Under whatever general title we may prefer to designate it (and certainly medical jurisprudence is the most familiar to English ears), it comprehends two great divisions, which are known by the names of medical police, and forensic medicine. More precise ideas of their respective objects will be imparted to you hereafter; I shall, therefore, now restrict myself to saying, that under medical police is comprehended, whatever information or assistance the medical man can give to the government of his country for the conservation of the general health of the community, and the removal of endemic or epidemic maladies. Upon the topics which more strictly belong to this department, I believe there is no very material difference of opinion among the members of our profession; and I do not consider that there is an urgent necessity for entering upon the formal consideration of them at present. Medical police, therefore, though not to be overlooked, is not to form an ostensible or prominent object in our projected course of study. To that branch, consequently, designated *forensic medicine*, our attention will be more particularly turned; and it is pregnant with matters of the deepest interest, not only to all of you, but to the community at large. It is that application of medical knowledge which brings the practitioner before his country, and in fact before the world, as the guide of tribu-

nals for the administration of law and justice. To the citizen in general the performance of so important a part is of the most interesting nature, and to the medical practitioner it is also of consequence. Every thing which he ought to hold dear is perhaps at stake, when he goes forward in the capacity of a medical witness; and no wonder if, unacquainted with the proper method of discharging these duties, he should falter, and even fail in the undertaking. There is nothing of a nature at all parallel to the dread and insufficiency which have long clung to medical men upon those solemn and momentous occasions. It is a situation in which the great Hunter himself broke down; and it is a lesson which one of the most celebrated of his successors inculcates upon his pupils, not many yards from where I am now standing, that medical witnesses should be *prepared*, while the same learned authority cites the personal admissions of the great man whose name I have quoted, as a warning; and yet, my friends, there does not exist the slightest occasion for all this, either in the nature of things, or in the nature of men. But the attention of our order has not been directed to this object. They have borne their perplexities as some persons bear their ailments, the best way they could—seeking no remedy, for, in fact, they knew not where to have found one; but—as a Jenner succeeded in propagating the knowledge and application of an antidote to one of the severest scourges of human nature, which had for centuries baffled the resources of medical art—so the medical jurist has at length shown his agitated brother how to encounter the solemn face of the judge, and the painful anxieties of the jury, with perfect coolness and satisfaction—has grasped him, as it were, by the hand, and led him to the altar, where he has enabled him to take that oath fearlessly, which he has, at the same time, instructed him how to fulfil religiously.

Now, it will be his own fault if a practitioner in such circumstances, does not *enhance* his reputation by similar displays on future occasions; and, as illustrations which come home to the feelings and circumstances of every one, are the most conclusive and instructive, I shall read to you an extract from a letter recently received by me from a person of whose existence I was previously quite unaware. After some remarks on a paper written by me upon the coronership, my correspondent thus expresses himself.

“With your paper I perfectly agree; and individually return my thanks for your unremitted exertions to place medical jurisprudence on its proper station in our professional education. In your researches you have not been able to discover more

than *three* cases of unalloyed credit to our profession for their satisfactory and intelligent evidence. Will you pardon me if I present myself before you, as having, in my own person, *three* times received judicial commendation; once from a bench of magistrates on a case analogous to the Gardiner peerage; and twice from his Majesty's judges; from Mr. Justice Littledale at the Somerset summer assize 1826, on surgical evidence arising from injury inflicted by the bursting of an iron safe containing gunpowder, removed in an act of burglary: and lastly, at the last Wilts assize from Mr. Baron Vaughan, in a case of infanticide." My correspondent after relating some particulars of the case, which I shall take a future opportunity of detailing to you, goes on to say, "But, my dear Sir, to whom am I indebted for this success?" you perceive that this gentleman appreciates the importance of professional publicity as it ought to be; "and from whom but yourself obtained I the means of *exalting* our profession? To your works on medical evidence and forensic medicine am I solely under obligation. I hereby present you with my most sincere thanks."

But although I am not, on the present occasion, about to enter into the merits of the trial (reserving it as an illustration when we come to the subject to which it more especially relates), I must gratify you, and do justice to the writer of this letter, by quoting the compliment which the newspaper published in his own neighbourhood tells me he received from the learned judge, who is brother to the president of the Royal College of Physicians. "At the close of his cross-examination the learned judge highly complimented him upon his skill and science, and told the jury in summing up that he never heard a more sensible and satisfactory evidence given by a professional man in a court of justice." Ought not such a thing as this to make any man's fortune, and is not this true brilliancy? But bright as it is, I am going to eclipse it all by an allusion to another act of beneficence which the profession has received through the medico-legal department.

I have myself, Gentlemen, received such handsome compliments from the judges of the land, that I have, for the last twelve months, abstained (out of modesty) from going to the Old Bailey, and yet I disregard it all, when I call to mind what has recently been done for you, and must be done henceforward, if you please to accept of it.

While "*stalled theology*," as Dr. Young\* says, has been keeping its eye upon a seat in the upper house of parliament, and behaving according to circumstances, in

order to obtain, first consecration, and afterwards translation, under the title of a right reverend father; while the busy *lawyer*, who, through the iniquities and perverseness of human nature, is really of such a degree of utility that we ought to deplore the fact, has been labouring away with applause and approbation, in order to become an hereditary peer of the realm; what has the *doctor* been doing? Allowing these people to make game of him in public, while their very existence, and consequently the successful issue of their ambition (laudable ambition, certainly), depended often in an exclusive manner, upon his advice and services. How finely *we* have been *humbugged*, if I may use so uncouth a term! The church is full of scholars no doubt, but sadly destitute of philosophers; and the energies of the lawyer, every-body knows, who knows any thing, are directed to objects of great magnitude; while the medical man, educated perhaps even more expensively, and certainly with more extensive liberality, concentrates equal powers, and devotes even superior acquirements, to the almost ridiculed purpose of prolonging for half an hour the life of some tiresome, and perhaps abominable, old woman, or devising the means of making an uninteresting and nasty brat go to the close-stool. Do not suppose, however, that I underrate these occupations: no man whose heart is in its right place can do so; and I have myself found it imperative upon me to perform with my own hands, relying upon my own skill, what may be termed the very meanest offices of the profession.

But we have now devised a method of raising ourselves from the low estate which I have rather alluded to, than truly and circumstantially described. We have at length opened to our brethren, and I should say to the *younger* class of them, glorious prospects through the *coronership*; and we shall neither rest satisfied, nor keep quiet, till the principle be in *all* quarters recognised, that the *CORONERSHIP* is an office for a medical man. Not that I consider every member, or even many members, or any but a very few members at present, *fit* to fill that situation; but I have come here, and I go elsewhere, professing to fit every rightly disposed medical man to become perhaps the most important of all judges. Take my word for it, that we have gained possession of this commanding post, and take this along with it, that we know how to maintain it.

I should retire from this place under an impression that I had not discharged my duty to its full extent did I not advert to a subject of the highest importance to every living man. It has, I am grieved to say, not been customary of late to introduce it in a formal manner; but it once was otherwise; and we cannot close an introductory dis-

\* Night Thoughts.

course, upon the character and qualifications of a medical man, in a manner more appropriate to the occasion, than by following the example of the learned, the amiable, and the celebrated author of the lectures on the duties and qualifications of a physician; better known perhaps to the majority of my audience as the elegant writer of the *Father's Legacy* to his Daughters. I mean, of course, Dr. John Gregory.

Can it be necessary, after this, to pronounce the word which is at the end of my tongue? You know what I mean—It is RELIGION. Let medicine, all the known mysteries of which are about to be disclosed to you, be associated with that *sublimity* which is already revealed, you know where, and medicine *must* rule the world. Why should the notion ever have been entertained that medical men are prone to infidelity? I deny it. The nature of our occupations may, it is true, have had a very general influence in separating us from the observance of certain duties of a religious, as well as of a political nature; but I am certain of this, that with the exception of clergymen, who live by the knowledge of the Scriptures, there is no class of men which possesses either so intimate an acquaintance with them, or more strictly regulates their lives and conversation according to the precepts there laid down. Indeed we cannot make a livelihood if we entertain other rules of conduct; and I am persuaded of nothing more firmly, however paradoxical it may sound, than that there are many men both in and out of the profession who are Christians without knowing it. But as I may perhaps be accused of wandering from my proper province, if I dwell much upon this subject, I shall go on to say that I mean by religion, the Christian religion. In fact there is no other in which a man of real sense can seriously believe. Some there are who perhaps do imagine that they believe in some other; but they are even ridiculously mistaken. It is CHRISTIANITY they believe in, if they have any belief at all. The morality, perhaps, of all prevalent systems is good, though it may be found here and there tainted with inconsistencies, and deformed by perversions, but whence is it derived? From the same source as our beautiful system, and through that channel. No man can disbelieve the Scriptures if he will turn his attention to one remarkable, to the most prominent, circumstance connected with them. Setting aside their style and composition, paying little attention to the well-established arguments with which so many able and good men have thought it necessary to confute the conceited *pseudo* philosophers, who have attempted to cut a figure in every age of the world, while I respect and reverence their labours, I say

that I set much of this aside; because there is another and a most entertaining source of confirmation, which has not been overlooked, though I am inclined to be of opinion that enough has not been made of it. We are misunderstood and unappreciated. We have a jealous world to deal with; and, at the present juncture, they are afraid of the distinction we are daily and justly acquiring. Let me entreat you to bear in mind that you aspire to belong to an order, dignified indeed; not forgetting that although you may be unable to accomplish the duties of religious observances so regularly as others have it in *their* power to do, you are the more strictly bound to respect them, because you are in a distinguished manner the servants of a God who has declared that he prefers mercy to sacrifice, or in other words, looks with higher approbation upon the **PHYSICIAN** than the **PRIEST**.

ON

## THE PLACENTA.

By WILLIAM DOBSON, *Surgeon*.

THE nature and use of the placenta have never been ascertained. The anatomist has dissected to unravel its structure, and the physiologist reasoned to develop its function, but after all their endeavours, nothing decisive is known of either.

It is the prevalent opinion, that the placenta effects some change in the blood in its passage to the *fœtus*,—that it purifies the blood,—that its purpose is to the *fœtus* what the lungs are to the adult: but of the *mode* in which this operation is performed, no explanation is offered. Does the placenta separate from the blood some of its elements, and are these returned into the circulation of the mother, while the remaining substance proceeds to the *fœtus*? Or, are the globules of the blood diminished in size, and the blood attenuated in this organ, so as to be adapted to the calibre of the minute fetal vessels? We have not one solitary fact, nor any well-grounded analogy, in support of either of these assumptions. Nor does there appear a necessity for any modification in the blood. And we possess a strong negative fact, that a change in the *elements* of the blood going to nourish the *fœtus*, is not required. The *fœtuses* of quadrupeds seem to be nourished in the uterus like the human class, yet a quadruped has no placenta; the communication between the mother and *fœtus* being established directly by vessels. And were it necessary in the one for the fulfilment of those objects, it is fair to conclude its necessity in the other.

The fetal blood differs little in its physical characters from that of the adult. The colour, however, both in the umbilical arteries and vein, is dark. This circumstance would seem to invalidate the idea universally entertained, that "the scarlet quality of blood is essential to nutrition and growth."

From the following position, that "the blood acquires a dark colour when detained from the lungs," it is analogically presumable, that on the long continuance of the blood (in the umbilical vein) from the maternal lungs, the dark hue depends. Hence an *opposite change* is induced on the blood by the placenta, to that by the lungs in the adult. It will be understood, however, that it is not from any *special agency* of the placenta that the blood is darkened, but simply dependent on its long detention from the lungs.

In a recent publication,\* I have adverted to the beautiful harmony subsisting between the vascular apparatus and its contents during health. But in the subject of the present inquiry, we find this equilibrium disturbed. During utero-gestation, the uterine vessels have their action increased,—they are carrying to the uterus an increase of blood to build up a new being, whilst the other parts of the body are deprived of their ordinary quantity. The system is in a state of excitability; the circulation is readily disturbed by a physical shock, or by mental emotions, which, in the unimpregnated state, would be received with impunity.

In the first few weeks of gestation the placenta is defective; the connexion between the mother and fetus is established nearly without the intervention of this organ. But the now imperfect placenta gradually increases in bulk, its union to the uterus becomes successively more firm, so that, near the latter part of this period, it requires considerable force to separate them; and it is in the early part of this process that abortion most commonly takes place. For at this time, the vascular connecting medium is easily destroyed; but subsequently the system can bear very considerable shocks, without injury resulting. The placenta at the ninth month is a large spongy mass, a span in diameter, and about an inch in thickness when uninjected, but can be considerably augmented by injecting the vessels; indeed the organ appears very elastic,—attached on its external surface to the uterus by means of the decidua vera; on its internal surface to the fetus by means of the funis. The structure of the placenta consists of branches of the uterine arteries and veins (*or of new vessels*), the two umbilical arteries and vein, all united together by cellular membrane. The manner in

which those vessels communicate is not understood. When the placenta is injected by the umbilical arteries, the injection returns by the vein, and only the fetal surface of the organ is injected. When injection is thrown into the uterine arteries it returns by the corresponding veins, the uterine portion of the placenta being injected. Between the maternal and fetal portions there is an appearance of cells, which are filled when the former portion is injected; there being no visible communication between the two circulations.

It seems obvious, that the placenta forms a bond of union between the maternal and fetal circulations; yet it appears not essentially necessary, for we find in quadrupeds as intimate and firm a connexion as in women: then, does it serve any other purpose in the human female economy? Here analogy is the only means to resolve this inquiry. When we contrast the human frame with that of brutes, we find a remarkable disparity; we perceive brutes to be little susceptible not only of mental, but of physical impressions; not easily influenced to that degree of excitement which would materially disturb the circulation of the fetus in utero; yet severe exercise will occasionally produce abortion, as is well known to breeders of cattle. But the human female during gestation has her mind and body highly susceptible, readily influenced by surrounding agencies; every little infringement on her rights disturbs the circulation; hence how necessary it is that quietude of the mind should especially be preserved, and that the physical frame should be guarded from every severe concussion! But these circumstances are familiar to all who have experienced, and those who have thought. Since the placenta does not appear requisite for effecting any change on the blood, nor essential for affording a bond of union between the maternal and fetal vessels, we may now conjecture, *that the placenta is for the purpose of receiving any undue quantity of blood which may be sent to the ovum, during excited circulation of the mother.*

Though we cannot obtain demonstrative proofs to substantiate this notion, analogical evidences ought to be admitted. In inquiries on the living body, we must often be content with these, the former being difficult to attain. The arcana of nature cannot always be developed in a palpable form.

It would appear, that in the first few weeks of the gestative period, only an imperfect placenta exists; but afterwards, it acquires a very considerable size; and it would seem that the liability to abortion is in an inverse ratio to the magnitude of the organ; and, as a negative fact, we may mention, that abortion in quadrupeds is most readily

\* On the Spleen.

produced in the latter months. These circumstantial evidences afford strong presumption of the placenta being a safeguard to the fœtus during excited circulation of the mother, probably receiving and detaining, in its cells, a quantity of blood, which otherwise would have been transmitted to the fœtus, and necessarily have injured its delicate organization, or the vessels between the uterus and ovum have become ruptured from over distension, and thus a separation produced, and the consequence, abortion. As collateral evidence it may be noticed, that when the system is disturbed, any part in a state of unusual action will be more readily influenced than a healthy part, as in the subject of examination—the uterine organs.

An argument might be advanced, and which would “*a priori*,” invalidate the general conclusion, viz., that in the early period of gestation, the ovum will act as a foreign body—as an excitant to the uterus by its distention, producing that tendency to expel its contents, and at a subsequent period, the sensibility of the uterus becoming blunted so as not to feel the impression. But in opposition to this view, we may state, first, that it is unphysiological to refer the enlargement of the uterus to distention; it ought to be considered a natural growth; and, secondly, that when quietude is maintained, abortion seldom occurs; it is only, *ceteris paribus*, when the woman has received some moral or physical impression, that a separation of the ovum from the uterus results.

We have here an example of that wise ordination of the Creator; though woman at this period is so susceptible to be influenced by surrounding circumstances, an apparatus is added to avert their agencies. The poor little fœtus, chained in its cell, would otherwise be doomed to suffer at every shock on its irritable parent, without either will or power to effect its escape.

Some apology may appear requisite for deducing this conclusion from so few premises; but the total impossibility of producing demonstrative evidence, will shield me from censure! Analogical testimony is, I conceive, too little appreciated, in physiological inquiries; I believe, if this principle of reasoning were oftener applied, we should arrive, with greater facility, at a more correct knowledge of the different phenomena in the human system; for when we find analogy in structure, we must look for analogy in function.

14, Arabella Row, Pimlico,  
October, 1830.

CASE OF  
RABIES IN THE DOG,  
CONNECTED WITH VIOLENT SPASM IN THE  
ATTEMPT TO SWALLOW.

By W. YOUATT, F.Z.S.

(From the *Veterinarian*, Oct. 1830.)

ON the 4th of last month I was sent for to Ealing. A cur had bitten a fine Newfoundland dog belonging to Mr. Anderson, and some other dogs and two pigs. It had been destroyed and buried, but was exhumed to be examined by me. A small quantity of dung and straw was found in the stomach, the cardiac portion of which was much inflamed with spots of extravasation. The whole of the pharynx, larynx, and mucous membrane of the windpipe, were highly inflamed, and the pleura pulmonalis was inflamed in patches.

On my declaring it to be my opinion that the cur was rabid, the Newfoundland dog was ordered to be destroyed. I, however, begged hard for him; and he was sent to my hospital for experiment. Various circumstances, over which I had no control, prevented the commencement of any experiment.

On the 19th, he did not feed as usual, and appeared dispirited. Fifteen days only having occurred since the bite, I did not dream of rabies, and ordered a physic ball to be given to him.

On the 20th, he had an anxious depressed look, with the lower jaw slightly dependent. Spasms stole over the face, and were particularly observable in the right eyelid. He was continually shifting his posture, and scraping his bed together; he slightly staggered behind; eagerly gazed at and attentively followed the path of some imaginary object. There was a great discharge of saliva, which he was frequently endeavouring to detach from the corners of his mouth with his paws; a grating choking noise in breathing. He was perfectly harmless; immediately came from his cot when called; offered his paw, and rubbed his head against me. He had not quarrelled with any of the dogs (likewise for experiment) with which he was confined; but being led near to another part of the hospital in which were the cribs of the sick dogs, he growled savagely at them. He was separated from the rest, and water put within his reach. He advanced towards it, looked at it, and turned away; he immediately returned, looked stedfastly at it, almost touched it with his muzzle, and suddenly started back: this he repeated several times.

I inoculated two dogs from him, which are well at the present time (Sept. 23d), and determined to try on him the power of the scutellaria. I boiled half a pound of the dried leaves in a quart of water half an hour, and straining off and expressing the liquid, I purposed to give two-ounce doses every three hours. He struggled most violently against the first dose; and when a portion of it, certainly not half, was got into his mouth, the attempt to swallow it produced convulsion of the whole frame; the eyes were distorted, and every limb was stretched out like the last struggle of expiring life. Being forcibly held, and unable to get it from his mouth, he, after the expiration of half a minute, swallowed it; but the gulp was peculiarly loud and violent. Being liberated, he fell on his side exhausted, and dreadfully panting. After the lapse of five minutes he came a little to himself, and crept to the further part of his bed, gazing intently upon me, suspiciously watching every motion, but faintly wagging his tail, and offering his paw when spoken to.

Our after-attempts to force him with the liquid were even less successful than the first. His resistance was most determined. He never, indeed, attempted to harm either me or my assistant; but he seized the butter-boat which we first used and crushed it to pieces; and he attempted to catch at the spoon which was then substituted. We could not contrive to get more than a third or fourth part into his mouth; that we retained there by forcibly holding up his head; but the spasm at the attempt to swallow became more and more horrible, and the exhaustion more complete at each attempt. I would not pursue the experiment, except to exhibit to a few medical gentlemen this unusual similarity to the characteristic symptom of rabies in the human being. At the suggestion of one of them, I substituted water for the decoction, when the effect was precisely the same. Every symptom rapidly increased; the eyes became red, with the expression of anxious wildness; the choking noise in respiration was greater; the heaving at the flanks became every hour more laborious, and was aggravated with every alarm, and almost at every motion; the lower jaw hung down more, and the tongue protruded discoloured. He frequently approached the water, and gazed wishfully upon it, and then retreated, and returned again to it. His strength rapidly wasted; and, on the morning of the

21st, he reeled as he walked, and in the early part of the afternoon was unable to stand. I forced the medicine once more upon him, when the effect was similar in character, but the spasm not so violent. He still knew me, and even when he could not rise faintly wagged his tail, and after many

an effort gave me his paw. He frequently looked at the water, which induced me to put it close to him; but, although he still frequently looked at it, he made no attempt to drink. A pan of clean water was placed beside him the last thing at night, more than a pint of which was gone in the morning, and the poor fellow was dead.

Circumstances delayed the examination of the carcase until decomposition had commenced. The stomach contained a small quantity of straw and hair, and half a pint of olive-coloured fluid. It presented one uniform mass of violent inflammation. The pharynx exhibited an intensity of inflammation which I had never before witnessed. The trachea was seemingly unaffected, and also the intestines; but the pleura of the lungs had the patchy character so often seen in rabies. The brain was one pulpy mass.

This experiment cannot be considered as elucidating any-thing decisive as to the effect of the scutellaria, for a small portion only of each dose could be got down, and the exhibition of it was soon suspended.

I purposely refrain at present from making any observations on the case,—they will better belong to a work which I have in contemplation, although it probably will not appear until a far-distant period: in the mean time, I thought that a case so unusual, standing almost alone as it regards the dog, should not be altogether withheld from the medical public.

DRS. RYAN AND GORDON SMITH.

“Audi alteram partem.”

To the Editor of THE LANCET.

SIR,—I trust you will allow me to offer a few words in reply to Dr. Gordon Smith's communications relating to me, which have recently appeared in your Journal. Had Dr. Smith adopted the usual course, which every candid man would have done, I should not be under the necessity of troubling you with this communication. As many of your readers, however, have seen his letters only, and not my journal which has given rise to them, I owe it to my own character, especially from the tenor of his articles in your last Number, to explain the real cause of the differences between us. The facts then are as follow:—

In the Medical and Surgical Journal for September, 1, as editor, made some comments on the medical evidence of *all* the witnesses who appeared at the inquest on the body of the unfortunate Miss Cashin, and among whom was Dr. Alexander Thomson. Dr. Smith, though he had not the ac-

quaintance of Dr. Thomson, with his characteristic impetuosity, rushed into the affair, commented upon my remarks on Dr. Thomson's evidence, and impatient to wait for my next number, inserted his reply in your Journal; and not content with scientific discussion, he deemed it proper to indulge in many sharp personalities against myself. It is right to state that for many months previously he and I were in constant correspondence, even to the day previous to his attack, when I received a note from him, apprising me of the forthcoming article, and assuring me that he intended it for my journal, but that the parties it most concerned would have it in yours. Here I must observe, that Dr. Thomson, to whom he alluded, denies that the article was sent to you under the circumstances stated. Dr. Smith was well aware that I could scarcely find time to conduct my own periodical—a monthly one, much less contribute to yours—a weekly one; and under such circumstances I must maintain, that he, or whoever transferred the article from my pages to yours, acted uncourtously and unfairly, by endeavouring to implicate me in a controversial correspondence in your Journal, and not in my own, to which, according to professional usage, the article ought to have been sent. Here I must pause and inquire, What right had Dr. Smith to comment upon my remarks, with which he had no concern, and more especially in a journal in which they had not appeared? He who had repeatedly professed the greatest respect for my advocacy and knowledge of forensic medicine, privately and publicly, to proclaim through your widely-circulated Journal, that I knew nothing about it. He who addressed a letter to me to be read before the Medico-Botanical Society, when the noble and scientific president, Earl Stanhope, and distinguished council, proposed me to the society as professor of toxicology, in which letter (and it was publicly read, though now denominated a private communication) is the following passage:—"If the expression of my opinion as to your eligibility can be of the slightest use to you, it is at your service in any shape, and I hope the day is not far distant when we shall be fellow-labourers, in the strictest sense of the word, and for the benefit of society, in a department of science hitherto known almost (I grieve to say it) *only to ourselves*." Yet this is the writer who denies that I know anything upon the subject. I must explain the cause of this very remarkable change in opinion.

A few days before the writer changed his mind, he requested my opinion on a memorial which he was about to forward to the Apothecaries' Company, on the necessity of enforcing the study of forensic medicine.

He observed, "I will give any alterations you may propose the most candid and deferential attention;" and he further requested my signature to the document, as the only lecturer on forensic medicine in London besides himself. On this, though not on former occasions, I forgot the story of Gil Blas and the Archbishop of Toledo, and did suggest many alterations, which my opponent admits, and *hinc illæ lachrymæ*. He states, however, that he did not adopt all, or scarcely any of my alterations; "this is most true," but he adopted enough (and it would have been better had he adopted more) to enable me to affix my signature, which I had refused to affix to the original memorial. The declaration that a very few words of my version were adopted, because Dr. Smith had made a promise to that effect, very well accords with the former promise of giving the most candid and deferential attention to my alterations. The truth is, had I acted in unison with my own feelings, I should not have signed the document at all; for I believed it an application which could have little, if any, influence on the Apothecaries' Company; and that opinion is now verified by Dr. Smith.

He states that I published his *private* communications; this accusation I have answered already, but must further remark, that no inducement whatever could justify me in so doing, not on my own account, but on his. This charge is so serious that it must be fairly met, however unpleasant to the feelings of both parties. Not one of Dr. Smith's letters, which contained his laudatory phrases, was marked private or confidential; and even if these letters were so marked, I ask any candid, honourable man, was I not justified in publishing extracts which solely referred to myself, and expose the writer, who, under the mask of friendship, contradicted in public what he so often stated in private? Dr. Smith fell into a serious mistake, when he considered that he might play this double part towards me. His complimentary remarks were never sought by me, they flowed entirely from himself, and he ought to have recollected this, when he penned his vituperative observations for your Journal. The fact is, and I record it with pain, had I published his private communications, they would place him and me in a very unenviable situation in the eyes of the profession, and in the eyes of some of the most scientific physicians of this metropolis. No; the "editorial guise," so far as I am concerned, shall never be a shield for the protection of those who are fond of personality. The less therefore that is said about private communications the better.

In the October Number of the *Medical and Surgical Journal*, I replied to Dr.

Smith's first letter, and confuted every one of his arguments from his own original works, and from many other works of authority. Instead of extricating himself from the dilemma in which I have placed him, he publishes two letters, one proclaiming that his acquaintance and mine had ceased at his desire, the other about the emended memorial. He has forgotten however to state, that he had written to me after the publication of his first letter, to which communication he received no answer, contrary to the punctuality which I always had observed towards him, and one would think he ought to have discovered that our acquaintance had ceased; yet several days afterwards he called on me, and renewed his large professions of friendship as usual, notwithstanding his letter in *THE LANCET*, "which upon his honour was intended for my journal, and sent elsewhere contrary to his wish and consent." I coolly informed him, that I had endeavoured to refute his statements in my next Number, chiefly from his own works. The journal appears, and then he writes the note dated 1st instant, informing me that our acquaintance had ceased, though I had considered it at an end on declining to answer his letter received several days previously; and as this event is of such great public importance, he has recorded it in your pages.

In the last Number of the *Medical and Surgical Journal*, Dr. Smith is refuted by himself; and there I have defied him, and I now repeat the challenge, to cite one author out of ten thousand on forensic medicine, who supports the doctrines he defends in his first letter; and I repeat the question I asked him at parting, "Does he seriously believe there is one eminent physician or surgeon in this empire who agrees with him in opinion?" Like all defeated disputants, he has the usual recourse to the *argumentum ad hominem*, and not *ad rem*; but this kind of logic is long since exploded. I now call upon him to confute my arguments against his heterodox doctrines, either in my journal or in yours.

M. RYAN, M.D.

Member of the Royal College of Physicians in London.

Hatton Garden, Oct. 11th, 1830.

#### WESTMINSTER HOSPITAL.

To the Editor of *THE LANCET*.

SIR,—In your Number of this evening (October 9th), I read a notice relative to the Westminster Hospital special general meeting of the 6th instant, in which you apply the term "jobbers" to one of the parties, and threaten or rather promise to

publish two or three documents that will, you expect, upset all their supposed machinations. Now "jobbers" is, whether justly or not applied, a very offensive term, and if not justly applied, is further calumnious and unwarrantable; I cannot, therefore, avoid entering my protest against the use of such injurious language in the pages of your powerful periodical, as I believe you have ignorantly applied it to gentlemen who constitute the majority, as the event will prove to you, "of the intelligent and independent governors;" gentlemen who, as you humanely hope, "will not fail to perform their duty to the subscribers and afflicted poor." Standing on a very high eminence in the field of medical politics, and having your attention divided amongst multifarious avocations, it is not probable that you can inform yourself accurately on a great variety of circumstances and transactions, which would naturally furnish matter for the critical pen of the editor of *THE LANCET*; and it is quite impossible that your information in numerous instances on interesting questions, can be derived from personal observation or inquiry; and I am not more fully satisfied of the truth of the general position just stated, than I am of that of the particular fact—that with regard to the views and proceedings of the influential party of the trustees of the Westminster Hospital, you have been grossly misinformed. It is with this conviction that I call on you, as in one sense a trustee of the interests of "the subscribers and of the afflicted poor," to suspend your judgment, or at any rate to hold your columns open with "equal and indifferent justice to all parties." It is my intention, with your permission, again to address the public on this subject, after I shall have read the documents of which you promise me the perusal in your next Number. Meanwhile I respectfully request that you will insert this in your next Number, and that you will believe me to be a sincere friend to publicity, and a friend, as well as subscriber, to *THE LANCET*.

C. R. M. S.

October 9th, 1830.

#### DERBYSHIRE INFIRMARY.

CASE OF ELLEN COPE.

To the Editor of *THE LANCET*.

SIR,—In offering a few observations on a case, the report of which is contained in your last Number under the head of "Derby Infirmary," I beg to state that I had an opportunity of seeing the patient daily, from the time of her admission to her death; and

as the minutes of the case, and *post-mortem* appearances, were recorded without any view to their being rendered thus public, I transcribe them from my case-book as they there stand; in order that they may not be regarded as "cooked up for THE LANCET," or biased in their details by a partiality which might lessen their claims to fidelity.

#### Case.

Ellen Cope, æt. 45, admitted Sept. 14, 1830, has a large and defined tumour in the abdomen, the upper and right side of which is hard and irregular; single woman; has menstruated regularly; general health does not appear much affected; says that she first perceived the swelling about two years ago, which has now attained an enormous size, giving to the abdomen the appearance of that of a woman far advanced in pregnancy: has a large bronchocele, which has been forming for the last four years.

*Hab. pil. hydrarg. c. rheo*, ij; o. n.

Common diet.

17. Ordered to rub in the unguentum hydriodatis potassæ every night over the abdomen.

21. Has slight headach, apparently from indigestion.

22. Headach better; pergat.

24. Was attacked this morning with an epileptic fit, which recurred whilst I was in the hospital; this attack was preceded by acute pain in the back, and sickness; pulse slow and feeble; tongue clean, but the breath is offensive; never had any-thing of the kind before. Discontinue the ointment.

25. Had a fit this morning; symptoms as yesterday.

26. After another epileptic attack she died rather suddenly.

#### Autopsy, twelve hours after death.

*Head.*—There is a slight effusion of transparent fluid between the arachnoid and pia mater; about half an ounce of similar fluid, contained in the cavity of the arachnoid, collected towards the base of the skull; no thickening of the arachnoid tunic, or deposit upon its surface; on lowering the head, a small quantity of serous liquid escaped from the spinal canal; about a tea-spoonful was found in the ventricles.

*Thorax.*—The lungs were generally of a dark-colour, and excessively gorged with blood; on cutting into their substance a quantity of frothy fluid escaped, with which the bronchi appeared filled, and which flowed copiously from the mouth. The left lung appeared in some parts impervious to air from excessive congestion; the heart and large arteries were healthy; the venous side of the circulation was generally loaded with dark-coloured blood, of which a considerable quantity was contained in all the cavities of the heart.

*Abdomen.*—The stomach appeared, externally, healthy, but, on opening it, the mucous coat was found very red, especially towards the cardiac extremity, and the villi generally minutely injected. The other viscera were apparently healthy. Attached to the uterus was an enormous tumour about two feet in circumference, rising into the abdomen, and occupying the situation of the womb during the latter months of gestation; two other tumours similar in texture, but not larger than a walnut, projected into the uterine cavity, covered only by its lining membrane. These tumours were formed in the substance of the walls of the uterus, which were expanded over the larger one for some distance unaltered in texture, but became gradually attenuated, so as not to be distinguished from the peritoneum, which likewise invested it. In structure these tumours very nearly resembled cow's udder, having all the characters of the mammary sarcoma of Abernethy. The ovaries were healthy, but the two layers of peritoneum forming their broad ligaments were separated by a small quantity of clear fluid.

Such, Sir, is the case, and such the *post-mortem* appearances, which seemed to Philanthropist sufficiently important to demand that the treatment adopted should be submitted to a coroner's jury as one in which the patient had been labouring under intense inflammation of the mucous membrane of the stomach, without its having been detected by her medical attendant; but I would just hint, that had Philanthropist known a little more about the appearances frequently presented by that organ, it would have saved him and some other *literati* of Derby much uneasiness, to which their *anxious care for the welfare of the patients in the Derby Infirmary* has, no doubt, given rise.

To remove therefore the impression, that wherever a "crimson stomach" is found, acute inflammation of that viscus has necessarily been the cause of death, even where a succession of epileptic fits had occurred prior to the decease of the patient, I will briefly refer to one or two authors from whom it may be learned that this is not the first case in which the stomach has been found of a crimson tint, without such a state being indicated during life; but, first, I will say a few words upon the luminous report which has called for these remarks. As a specimen of the candour of this *gentleman*, it is only necessary to point out that the fits, the immediate cause of the woman's death, are not mentioned! In proof of his veracity, I would remark that the statement that the woman "was extremely sick for a day or two before her death, in short, that nothing would stay upon her

stomach," is false. She stated to me as the cause of her fits (and certainly with much probability) that she had eaten some barm-dumpings, which "lay very heavy upon her stomach," nor did she ever complain of the slightest pain or tendency on pressure being applied over the abdomen.

I now proceed to the questions propounded by this reporter for elucidation:—What caused the inflammation, and why were no remedies used to subdue it? The inflammation, or rather the suspicion of inflammation, arose in the ignorance of Philanthropist, and means were not used to combat it, because it had no other existence. In conclusion, for the benefit of Philanthropist in particular, and of the governors of our Infirmary in general, I will refer to authors from whom some remarks on this important subject may be extracted. In Boyer's *Traité d'Anatomie*, we find the following salutary caution:—"Le grand nombre de vaisseaux qui se distribuent dans cette tunique (la veloutée) lui donne souvent une couleur pourpré obscur; c'est à quoi il faut faire la plus grande attention lorsqu'on est chargé de faire l'examen des corps de personnes que l'on soupçonne mortes de poison."

In the "Medico-Chirurgical Transactions," vol. iv, we find recorded twenty successive *post-obit* examinations of patients dying in the London Hospital between the 1st of April, 1813, and the 27th of May in the same year, in which the mucous membranes of the stomachs were found in all states of vascularity, from the rosy tint (given by Bichat and Cloquet as the most natural appearance) to shades of scarlet and even crimson, without such a state being at all indicated by symptoms during life; in this valuable paper, written by Dr. Yelloly, the result of that gentleman's observations is stated as follows:—"In the villous coat of the stomach, appearances of vascular fulness, whether florid or dark-coloured, in distinct vessels, or in extravasation of various sizes, are not to be regarded as unequivocal marks of disease; they occur in every variety of degree and character, under every circumstance of previous indisposition, and in situations where the most healthy aspect of the organ might be fairly expected. It would be useless to multiply authorities. I refer to the book last quoted for full information on the point under consideration; and merely hint that the "crimson stomach" is not "put under the sod" as Philanthropist asserts, but still remains a monument of his ignorance, better worthy of being concealed by silence, than of standing emblazoned on the pages of your extensively circulated Journal.—I am, Sir, your obedient servant,

T. M. JONES.

Dorby, Oct. 6, 1836.

#### MR. WALFORD AND THE PUPILS OF THE LONDON HOSPITAL.

"There's never any of these demure boys come to any proof; for thin drink, and making many fish meals, doth so cool their blood, that they fall into a kind of male green-sickness; and then, when they marry, they get wenches; they are generally fools and cowards."—SHAKESPEARE.

#### To the Editor of THE LANCET.

SIR,—I was advised to forbear acknowledging the favour of the Whitechapel manifesto, on the grounds of the insignificance of the declarants, and the helplessness of their idol. "What maist the priests be whers the god is a monkey?" was the traveller's reply to a question after the sythe legion of a Pagan people. I should certainly adopt the advice, were it not for some peculiarities in a letter from the innocents of Whitechapel.

In the letter which provoked the wrath of the "harmless little men," I made honourable mention of Sir W. Blizard; him did I blaspheme, as well as vituperate Mr. Headington: why, therefore, did they not defend the knight as well as the squire? I can solve the problem. Of the *eight-and-thirty*, who have so handsomely done Mr. Headington's business, and set him up with a character, a few will present themselves for examination during the presidency of the object of their lick-spittle adulation; and, should some trembling idiot break down, does he not hope that the remembrance of his servility will stand him in good stead? Of course he does.

I perfectly agree with the *thirty-and-eight*, that no man has a right to defame the character of another, because he differs in opinion; and I ask these discerning youths, if there is no difference between the record of a fact and a defamatory falsehood? They feel a pride in being under such a master; of course they do, and doubtless the master is proud of such pupils; the pleasure is reciprocal, and the pupils are worthy of their preceptor. They say they flatter themselves that Mr. Headington's differing in opinion from me is the sole cause of my hostility to him. In this they do flatter themselves, and that is all. I pronounced Mr. Headington's degradation, not because his opinions were opposed to mine, but that his principles are. Mr. Headington has long been a member of a body whose acts have ever been opposed to the best interests of the profession and humanity; whose laws are the dictates of a sordid love of gain; and whose gains are the fruits of the most unprincipled rapacity.

The *thirty-eight* reap over my hostility to Sir William Blizard, and content them-

selves with piously wishing that every man may possess, at ninety-two, the "mind and intellect" of that atrabilious examiner. The wish is a good one, but, considering the wisdom of the *eight-and-thirty*, I marvel much the they did not wish every member of that profession the knight's "soundness of mind and intellect" during the whole of their natural lives. The "soundness of mind and intellect" of the *thirty-and-eight*, even Sir William need not envy. Is a wish for the mental prostration of their fellow creatures all the sympathy they can bestow on the sorrows of Sir William? Is a wish that every man of ninety-two may be so weak as Sir William, all the pity they can bestow on a poor old man? I am ashamed of them. Even Sir William, were he young enough, would blush for his apologists. They affirm that they would not be ashamed to advocate a medical coroner; perhaps not, for as they are not ashamed of themselves, it is very clear they could not be ashamed of anything. Why do they not say, that like their master they would be afraid to support one?

They are not happy in their tail piece. Were it not better to adopt an alteration, and, instead of tacking it to Sir William, apply it to themselves? For instance,—  
"If such the morn, how dull the eve must be."

I am, Sir, your faithful servant,  
W. AUGUSTUS WALFORD.

October 9th, 1830.

## LONDON MEDICAL SOCIETY.

October, 1830.

### TREATMENT OF ERYSIPELAS.—SUPPRESSION OF UTERINE HÆMORRHAGE.

THIS Society resumed its sittings on the last Monday in September, but so quietly, that we were not, at the time, aware they had again commenced. On attending this evening, Oct. 11th, the discussion proved to be a continuation of that with which the meeting on the previous evening had closed, when a case of erysipelas of the face was read, in which puncturing, with the exhibition of opium and ammonia, had produced a favourable result. Some of the gentlemen then present had given their testimony in favour of, and some against, the practice of making punctures; and according to their several views of the exciting cause of erysipelas, a variety of treatment was recommended. Many of the members now detailed other treatment which their experience had determined to be successful, and this, as commonly happens, was very various. Opium was recommended and condemned; the

acetate of lead, as a lotion, was approved and depreciated; quinine and sherry were extolled and censured; and after many other plans had been declared both successful and injurious, as circumstances seemed to warrant, tartarised antimony, and antimony alternated with the liquor potassæ, were finally referred to as very advantageous and rational modes of subduing the disorder.

A letter was afterwards read from Mr. Samuel Miles, of Runcorn, in Cheshire, on the subject of a new belt for the suppression of uterine hæmorrhage; the letter was addressed to Dr. Merriman, by whom it was laid before the Society, together with the apparatus to which it referred. Mr. Miles stated, that he was a pupil of Dr. Merriman in 1817; and communicated his design to the Doctor as a mark of his regard. The letter briefly stated, that it had been the writer's lot to see so many fatal cases of uterine hæmorrhage, that he had turned his attention to the best mode of arresting it. External and equal pressure appearing to be the most rational, though but ill effected by the employment of books, towels, pillows, and the hands, he had designed the present instrument, which he begged to distinguish as "Miles's uterine tourniquet." It consisted of a belt nine or ten inches broad, to be fastened round the hips with straps and buckles, permitting pressure to be made on the abdomen by means of a circular plate, also nine or ten inches in diameter, covered with leather, over the centre of which were a brass frame and screw, permitting the pressure to be increased or diminished at pleasure. The apparatus might be regarded as a common tourniquet on an extended scale.

Dr. MERRIMAN, on being asked for his opinion of its efficacy, stated, that he had only had the opportunity of placing it on his own body, which, however, had enabled him to ascertain, that it was capable of exerting great pressure, but whether sufficient to restrain uterine hæmorrhage or not, he could not tell; certainly, unless the uterine were empty, pressure either by that or any other means could be of no use. There was, he thought, one essential objection to the instrument; if the hæmorrhage began before the bandage was resorted to, the attempt to place it on the patient would very probably do more harm than the good which could afterwards result from its use. It would not be easy to put it on and buckle the straps without raising the woman, a very dangerous proceeding at the best. The only case in which it could be useful would be where it could be known beforehand that the patient was liable to profuse hæmorrhage in child-bed. To any female of that kind it would be serviceable.

It was objected by Mr. KINGDOM, that the compressing pad did not descend suffi-

ciently below the level of the circumscribing belt to make the pressure effective on the uterus, as at present the strain would be almost equally made on the bones of the pelvis. Mr. Kingdon mentioned a belt made by some poor woman, which was worn before delivery, and effectively tightened immediately after by strings, attached for that purpose. Dr. Blicke bore testimony to its advantages. Mr. DENDY considered that Mr. Miles' instrument, by compressing the uterus between the pad and the promontory of the sacrum, would prevent, and not assist, the action of its muscles. The subject led to a discussion of the merits of the various modes in use for suppressing hæmorrhage of the uterus. Dr. Blicke thought plugging of the uterus and vagina the most effectual; Mr. Browne extolled the cold affusion; Mr. Shearley, the acetate of lead; Mr. Waller, bandaging, if it were only for the comfort it afforded; and Dr. Walshman, the insertion into the uterus of a sponge and tape, after clearing out all coagula, keeping the sponge in the uterus three or four days.

## LAWS RELATING TO THE PROFESSION OF MEDICINE.

*To the Editor of THE LANCET.*

SIR,—Permit me, through your medium, to draw the attention of the profession to a subject of the greatest importance: it has been frequently stated, and is pretty generally believed, that the Royal College of Surgeons has no power to hinder any individual from practising for his own benefit; this however is erroneous; and to prove this I will quote a passage from a work just published, and which should be in the possession of every medical man.\* It is from Mr. Willcock's truly valuable treatise on "The Laws relating to the Medical Profession," &c.; and at page 82, sect 11, is the following:—

"Every person, except a *physician*, however learned or skilful he may be, is liable to a penalty of 5*l.* for every time wherein he may practise surgery within the cities of London or Westminster, or within seven miles of London, for his private lucre or profit, before he has been admitted to practise by the College of Surgeons; one half of this penalty is given to the king, and the other to the public use of the commonalty or society; and the masters or governors for the time being are empowered to recover

the same by action in any court held within the city of London." "I am not aware," observes Mr. Willcock, "that any proceedings have ever been instituted under this clause of the charter of Charles the First, which is, by way of reference, incorporated in the act 18 Geo. II. c. 15, by section 8.† And there may be some doubt whether, notwithstanding the words of that section, such penalty can be recovered in any manner, *except* by an action in a court of record, or other public court of the country; for although the charter proposes to give the corporation the power of distress, such power cannot be exercised without making the College both judge and party, and giving some, or the whole, of the members of it, authority to hear and decide in their own cause, which neither the charter nor the statute pretends to give them, and which Lord Holt has said the Legislature cannot give."

"Every person, except a *physician*, however competent he may be, is liable to the penalty of five pounds for every month during which he may continue to practise surgery in any part of England, *except* London and Westminster, and seven miles around the former city, unless he has been admitted by the College of Surgeons, or approved of by the *ordinary*, or, in his absence, by the *vicar-general* of his diocese, and the other appointed persons by 3 H. 8. c. 11. The proceedings under this act against a person practising surgery are similar to those which may be instituted by a common informer against an unqualified physician."

This being the case, and from a perusal of the act of 18 Geo. II. c. 15, and of the charter of the 22d of March, 40 Geo. III., I find the above, together with divers other privileges, confirmed in the most positive manner; and although the president and council of the Royal College of Surgeons have not yet thought proper to put these penalties into force (which in the case of some empires that could be named they ought), yet I, as an humble member of the profession, consider it to be my duty to give this information, and thus afford those liable to the penalties, the power of avoiding any actions which, from this work, it appears the College has the power of instituting against them. And thus let the old adage be borne in mind, that "*a preventive is better than a cure.*" And I would strongly advise every professional man to peruse the work in question, as it contains much judicious advice, combined with a mass of valuable medico-legal information. I have to apologize for the length of this letter, but the subject would not admit of

\* Vide Charter, 15 Aug. 5 Car. I. clause 9, inserted in the same work, p. 181.

† Ibid. p. 186.

curtailment, and trusting to your kindness to admit this in your Journal,

I remain yours obediently,

H. W. DEWHURST, Surg.

Grosvenor Terrace, Oct. 1830.

We shall say a few words on the work of Mr. Willcock in our next Number. Medical law is now the universal topic. It is an error, however, to suppose that the College of Surgeons has the power to prevent unqualified persons from practising surgery. The Corporation of Surgeons, which existed under the act of 18 Geo. II., expired, or was dissolved, about 1790. The present College of Surgeons, therefore, is, comparatively speaking, a new institution, and was founded under the charter granted by George III. That charter, as it has not been confirmed by Act of Parliament, could not confer upon the members of the Council the privileges that were enjoyed by the Corporation under the Act of Geo. II. If the College of Surgeons possess the powers which Mr. Willcock the barister has conceded to them, why did the Council apply for a *protecting* Act of Parliament in the year 1816? The College took the best advice on the subject. It was well understood that it had not the power to prevent the intrusion amongst the public of unqualified surgeons; therefore it was anxious to obtain an act from the Legislature which should compel all persons who were about to practise surgery, to purchase a diploma from the College. Lord Gifford, the then attorney-general, and the present Lord Chancellor, the then solicitor-general, both stated as their decided opinion, that the College had no power over unqualified practitioners. Hence the application to Parliament; but the Legislature having, in 1815, been nauseated by the Apothecaries' Company, the members of the House of Commons, persons not possessing the most sound constitutions in the world, could not find stomachs for any more physic. The job therefore was rejected, and principally through the exertions of Sir Robert, at that time Mr., Peel. We want one, general, comprehensive law, which can be easily obtained if the members of the profession will only exert themselves in a proper way. We shall endeavour to assist forthwith in the goodly undertaking.

## THE LANCET.

London, Saturday, Oct. 16, 1836.

UPON a further inspection, we are not inclined to give publicity to the documents referred to in our last number, concerning the affairs of the WESTMINSTER HOSPITAL, because they are of a nature to place the question upon too narrow a basis, and because they involve many private matters which ought not to be introduced in the discussion of an important public question.

A Correspondent, whose letter we insert at page 108, takes exception to the term "jobbers," which we applied to the promoters of the scheme for rebuilding the hospital at Charing Cross. The expression is certainly a harsh one, and the more so because it is felt to be appropriate by the persons for whom it was intended. At the same time we are most willing to confess that it would be scandalous if we were to insinuate, even for an instant, that the whole party of Trustees, who advocate the removal of the hospital from its present site, are influenced by any motive other than a most ardent desire to uphold the best interests of the charity. It is not right to impute improper intentions to any governor who may support the proposition for removing the hospital to Charing Cross, even if it should be demonstrable that his own private interests would be materially benefited thereby. Neither is such evidence conclusive that the undertaking would be detrimental to the poor, prejudicial to the public interests, or unjust towards the founders of the hospital. The reasons that are advanced on both sides of the question should be carefully considered, and imputations upon motives ought to be studiously avoided; but an opinion delivered on either side of the question, if unsupported by argument, should not have greater weight in deciding the question, than a mere silent vote. What, then, are

the alleged reasons for rebuilding the hospital at a distant place? They are all comprehended in two brief propositions:—

1st. That the removal of the building from its present situation to Charing Cross, would lead to an increase in the amount of subscription, and, therefore, the hospital would be enabled to accommodate a larger number of patients; and,—

2ndly. That the removal is likely to be attended by a very considerable increase in the number of medical students.

A very few words will be sufficient to show, that the arguments in support of this last proposition, if they have any weight at all, press decidedly against the projected removal; for the scheme contemplates neither more nor less than the conversion of a Hospital, established in Westminster for the benefit of the poor in its immediate vicinity, into a medical school in the neighbourhood of Charing Cross, for the benefit of the medical officers. The treasury of the hospital possesses 74,000*l.* of funded property. Now we ask,—Was this money bequeathed to the necessitous sick poor, or to the projectors of a medical school? As no one will have the temerity to contend that the terms of any one of the bequests refer, in the most distant manner, to the latter undertaking, the appropriation of even five pounds of the hospital funds to such a purpose, would be a precedent of most dangerous tendency,—would be such an outrageous perversion of the intentions of the benevolent donors, that it might not only prove destructive to the existing property of the charity, but might prevent all future subscriptions, by causing a just apprehension of a want of discretion and capacity in the trustees.

From the whole tenor of the discussions which have taken place in this Journal upon the subjects of hospital discipline and medical education, we hope it will be admitted that we have not, on any one occasion, been unmindful of the interests of medical students; but we have never yet been enabled

to discover in what manner the patients of a hospital are immediately benefited by the bustle and confusion constantly created in the wards by the presence of large crowds of young gentlemen, whilst the pupils themselves, thus collected by the monopolizing and mercenary by-laws of our colleges and medical companies, are utterly incapable of acquiring that information of which they are so anxiously in search, and for which they so dearly pay. The governors, therefore, have little reason for believing that the unfortunate patients will be benefited by converting their hospital into a “large” medical school, and even the medical officers themselves must admit, if they speak truly, that, with regard to affording adequate clinical instruction to the student, the pupils of the Westminster are already sufficiently numerous; for it were idle and monstrous to suppose that a hundred and fifty, or two hundred gentlemen, can approach near enough to the bed of a patient to hear either questions or answers, or even to obtain, in the majority of instances, a glimpse of the characters of the disease under treatment. Hence, if the medical officers were men of talent, regular in their attendance, and punctual in the delivery of judicious commentaries, on the diseases and their treatment, the *Westminster*, from the very circumstance of its having only such a number of pupils as are enabled to see the sick, to hear the lecturer, and observe the effects of the remedies given to each patient without obstruction or molestation, it might be esteemed the best, the most efficient, hospital for clinical instruction in this metropolis. Enough has been advanced, then, to demonstrate that the interests of the public, as connected with the education of medical students, and the comfort of the unfortunate patients, as affected by the inconveniences arising from a large medical school, loudly demand that the hospital should be re-erected in its present situation.

The arguments by which it is endeavour-

ed to maintain the first proposition, are equally as unsubstantial and baseless as were those advanced to support the second. It is conjectured by the "removal" party, that if the hospital be removed from its present "obscure" neighbourhood, it will be more liberally supported, and, consequently, that it will be enabled to relieve a numerous assemblage of patients, *Obscure neighbourhood!* Why it is situated in the high road from the western part of the county—from Chelsea, Putney, Hampton, Hammersmith, Kensington, and Knightsbridge?—Why it is situated in the high road from Hyde Park Corner to the Houses of Parliament, to the Abbey and the Courts of Law!—Why this "obscure" hospital in an "obscure neighbourhood," is within a hundred and fifty yards of the King's Palace, upon which a million of money has just been expended. In this situation, according to the annual reports of the governors, according to the yearly gratulatory addresses of some of those very gentlemen who are now so boisterous in their demands for a removal, it has existed and flourished one hundred and eleven years; it has relieved upwards of two hundred thousand diseased poor persons; it has accumulated seventy-four thousand pounds of funded property, and there are twenty thousand pounds which have been liberally subscribed by the public for rebuilding the hospital. In the same reports it has been invariably alleged that, in the management of the funds of the charity, there has been no jobbing, no peculation, that the patients have been most scientifically and liberally treated, and, in a word, that there has not been a better conducted hospital in London. Under these circumstances it really would appear that none but the ignorant or the designing would hazard the welfare of the poor, by demanding for this institution a new situation. But, it is contended, that were it erected at Charing Cross, it would be enabled to support double the number of patients. Fudge! The persons who urge

this argument must be short-sighted indeed, or they would perceive that it goes to support the erection of the Charing Cross Hospital, an undertaking for which a fund of ten thousand pounds is already collected, and not to prove a necessity for the removal of the Westminster. Large hospitals, it is well known from painful experience, are advantageous, comparatively, neither to patients nor to pupils. The talk of "junction," therefore, between the two institutions is, we trust, a mere idle rumour. Charing Cross doubtless will have its hospital without the removal of the Westminster, and as it is a spot whereon no hospital has stood for so many centuries, why has it become necessary that two should be erected there all at once? In truth, any hospital is less required there now than it was some few years since, as the foul courts and alleys have been all swept away in effecting those splendid improvements, which are every-where observable in that neighbourhood. The Westminster Hospital at present stands upon its own freehold; but, if erected at Charing Cross, it will incur a ground-rent, we hear, of eight hundred pounds *per annum*! Is this just? Is it politic, thus to swallow up four-fifths of the present annual contributions in *rent*, when the whole might be reserved, and employed in adding to the comforts of the afflicted patients? The hospital can be erected upon its own ground, in a situation that will prove far less noisy than near Chandos Street; and, as to salubrity, there is no comparison between the two places, for it is now at the very border of the Park. The medical officers have never yet complained to the public, that erysipelas, hospital gangrene, and hospital fever, are common in the wards of the "old Westminster." It has spread no contagious diseases in the neighbourhood, and these circumstances afford strong grounds for believing, that as far as pure air is to be obtained in this metropolis, there is no hospi-

tal in London more fortunately circumstanced.

From the considerations which we have here briefly enumerated, we confidently hope and expect, that the governors will faithfully discharge their duty to the poor, the public, and the profession, by re-erecting the hospital upon the freehold estate, which they hold in trust for the benefit of the institution.

#### INQUEST AT HAMPTON.

MR. JEWEL has addressed a note to us in which he denies that he approves of the employment of considerable force in the practice of midwifery. Mr. Jewel will excuse us for inviting his attention to the following evidence\* :—

ANN ELLMAN. Mr. Bowen used his instruments with very great force; he put his back against the wall, and his feet against the bed, and pulled with a napkin with all his force. Something then gave way; the sound was like a bit of stick breaking, and the witness saw a child's arm pulled off.

MARY ANN ELLIOT.—Mr. Bowen asked for the boot-hook, which he used, placing his feet against the bed, and pulling with violence. I saw him take off both arms; one he pulled off.

SARAH CHILMAN. When the arm came off, he had got a napkin round it, and was pulling very hard, and witness said, "The Lord have mercy on us."

GEORGE JEWEL examined. Do you think that Mr. Bowen acted *properly* in this case? —I DO."

This is the way to strip evidence of its useless verbiage.

*Practical Observations on Leucorrhœa, Fluor Albus, or "Weakness," with Cases illustrative of a new mode of Treatment.* By GEORGE JEWEL, Surgeon, &c. London: Wilson. 1830. 8vo. pp. 108.

Of all the "new" works it has ever been our melancholy duty to examine, this affords the most instructive specimen of the craft

and mystery of writing a book. Throughout its one hundred and eight pages we are prepared to prove that the author can only lay claim to two ideas peculiar to himself; the first of which is, that local irritation, determination, or inflammation, is the immediate exciting cause of leucorrhœa; the second, that the application of the solution of nitrate of silver is a specific by which, under all its forms, it may invariably be cured. Within this narrow space resides every merit of the treatise, notwithstanding all that has been said and sung in its celebration; and even in these two points we have some reason to believe that priority of printing is the utmost to which he can pretend, for we have long known the nitrate of silver to be used as an injection in this disease, and we also know that the exciting cause was ascribed to local irritation or inflammation, by a great number of practitioners, long before Mr. Jewel favoured the public with his views on the subject. Inexperienced authors will doubtless imagine that out of such a meagre text it must have been difficult to construct a book of seemly dimensions, and certainly no little credit is due to the artist in the present instance, for the success with which he has spun out his grain of gold into a lengthened wire. We admit that even after an attentive perusal we are still ignorant of his method of amplification, the distinguishing characteristics of which are, a very bad style of composition, and numerous ill-digested opinions and statements, which it would not be very easy for the author to justify, were the critic to press him hard for his defence.

On the source of the increased secretion Mr. Jewel's book affords no information derived from the author's own necrotomic inspections, but he has contrived to perplex the subject a little by expressing the following opinion, which he presently disproves in a most satisfactory manner. "I believe," he says at p. 9, "that the discharge seldom issues from the uterine cavity;" while at p. 39, we find him noticing the following important data, from which we believe his first conclusion can scarcely be legitimately derived. "Here," he proceeds, "it may be necessary to state that M. Blatin examined the bodies of twenty-four females who died from excessive leucorrhœal discharge, with

\* LANCET, No. 371, page 76.

a view of ascertaining the seat of the disease. In nine of these cases, the morbid secretion was found to arise from the *uterus*, in thirteen from the *neck of the uterus* and *vagina*, and in two from the *fallopian tubes*. At p. 34, Mr. Jewel alludes to M. Lisfranc's operation of the removal of a part of the *cervix uteri* when affected with carcinomatous disease; he mentions the report communicated to the *Académie Royale* of forty cases of operation, *three* of which only terminated fatally; yet a few lines further on he states, as an objection to excision, that "the operation gives a shock to the system sufficient in itself to destroy life."

In his enumeration of remedies, he omits the *cubeba*, which, by report at least, have been tried with great success in this disease; he also commits the pharmaceutical error of prescribing together the carbonate of potass and sulphate of magnesia, as the basis of an effervescing draught. We declare with regret, that, from all these circumstances we cannot recommend the book to the notice of the profession. As we have already stated, all that is valuable in it resides in so narrow a compass, that with the exception of a few illustrative cases, it would scarcely form an admissible article for any journal of repute. Of the practical value of the nitrate of silver, we can offer no opinion, and its utility can alone be proved by extensive clinical experiments.

We are glad, however, that under the same cover, though not a part of his "Practical Observations on Leucorrhœa," Mr. Jewel has afforded us an opportunity for noticing him in a favourable manner. We allude to two cases of gonorrhœa, with excellent preliminary observations, which he has given in a brief appendix, and without subscribing our assent to his doctrines, we cheerfully subjoin the following abstract of his opinions on the possibility of secondary symptoms arising from gonorrhœa, and one of the cases treated by the injection of the nitrate of silver.

"There is one question which I conceive to be of infinite importance, and which is still considered by many to remain undecided. Can gonorrhœa give rise to secondary symptoms? Whether gonorrhœa and syphilis are two diseases widely distinct from each other, or one and the same, I have every reason to believe, from facts and observations, that secondary symptoms, such

as papular eruptions, blotches, and sore throat, do occasionally appear after the former disease, when it has been unusually severe or protracted, and especially when it occurred during utero-gestation. A modern writer\* has stated his belief, that as long as sound surfaces remain, to which the matter has been applied, no secondary symptom of a specific character follows, that in fact no poison is formed. It would therefore appear, that in order to the production of secondary symptoms, the mucous surface must be broken, or that there necessarily must exist a gonorrhœal sore or excoriation, in which case the matter would be absorbed into the system. Upon this point of the subject I would remark, that I have always been carefully minute in my inquiries into the history of such cases, and that in the majority I have not succeeded in ascertaining that a sore had been detected at any period of the disease, although the fact of the gonorrhœal complaint had been most readily admitted. I have so often observed secondary symptoms following gonorrhœa in pregnant women, that I have long since thrown aside all doubt upon the subject, and have for several years invariably had recourse to the alterative action of mercury, as in the exhibition of the *hydr. cum creta*, with a view of suspending the disease, and preventing secondary symptoms from taking place."

The annexed case of gonorrhœa, "cured" by the nitrate of silver, we think is highly deserving the attention of practical men.

"Dec. 9. A. R., a poor woman, 25 years of age, states, that she has been infected with gonorrhœa about three weeks. The vaginal secretion is highly acrid, and there is a glandular enlargement in the right groin. The living membrane of the urethra is particularly sensible, and she complains of great soreness in the pudendum; bowels confined.

R. *Infus. sennæ*, ʒvss;  
*Pulv. jalapæ*, ʒi;  
*Potass. supertart.* ʒij;  
*Syrup. zingib.* ʒss. *M. ft. mist.*  
*sumat partem quartam pro dosi.*

To take diluents plentifully, and to abstain from all stimulating food and drinks.

11. *Argent. nitrat.* gr. xxiv;  
*Aq. distil.* ʒviij. *M. ft. Injectio*  
*ter in die utend.*

*Hydrarg. cum creta*, gr. v. *bis quotidie.*

14. The symptoms are relieved, except the pain which is felt when the patient voids her urine.

*Continuentur remedia.*

17. The vaginal discharge has disappeared, but the local irritation continues.

\* Mr. Travers.

To increase the strength of the injection, (nitrate of silver, gr. iv, ad ʒi aquæ.)

*Cupiat mist. parv. ut antea.*

23. In every respect much better. There is no vaginal secretion, and she voids her urine without pain. To continue the injection.

26. There is still a hardness in the groin, but, with this exception, the complaint is entirely removed.

These cases, which I have selected from others, merely from their having been almost the first of the kind of which I had taken notes, illustrate two practically important points; first, that the nitrate of silver will prove a therapeutical agent of great value in the cure of gonorrhœa in the female; and secondly, that it may be employed with perfect safety and advantage, notwithstanding the presence of inflammatory symptoms."

### INQUEST AT HAMPTON.

LETTER FROM SIR ANDREW HALLIDAY.

*To the Editor of THE LANCET.*

SIR,—In the report which you have given in last week's LANCET, of the evidence taken at the inquest at Hampton, on the 2nd inst., there are two errors, which, though perhaps of little moment, I hope you will do me the favour to correct in your next number.

First,—Mr. Bowen did not call upon me to explain the reports that were in circulation. He came accidentally into my room about half an hour after I had first heard of the report from Mr. Sells of Kingston. I repeated to him (Mr. Bowen) the statement as made to me by Mr. Sells, and in the very words in which it had been made, and as he *unreservedly assured me* that that statement was not true, I wrote the words down upon a slip of paper, told him the name of the person from whom the report had come (a Mr. Russell of Hampton), and said he ought to go instantly and have it contradicted. My words were, "*Take this paper, and tell Mr. Russell that you have my authority for saying that he has been propagating this false report, which you can read to him.*" So fully was I impressed from what Mr. Bowen said, that on meeting Mr. Sells about half an hour afterwards I stopped him in the village of Hampton, and in a manner exclaimed, "*I am delighted to be able to assure you that the report you have heard about Mr. Bowen is all lies!*"

Secondly,—that however the evidence may have been taken down, my answer to Mr. Guy's first question was, *that Mr. Bowen*

*had never told me that he had taken off the child's arms.* Had Mr. Bowen been examined, as I conceive he ought to have been, and as I fully expected he would have been (as he certainly was the only person that could give the coroner and jury any information), I should have had the opportunity of making him explain the now apparent inconsistency between my assertions in the first instance to Mr. Sells, and subsequently to Mr. George Taylor of Kingston; and my reply to Mr. Guy's first question as stated in your report of the inquest.

My own feelings would have induced me to have troubled you at much greater length on this unfortunate business, in which great efforts have been made to implicate me personally; but I cannot expect that your valuable pages are to be occupied with such private concerns, however important they may be considered by,

Sir, your very faithful servant,

ANDREW HALLIDAY.

Hampton Court,  
Oct. 13, 1830.

LETTER FROM MR. JEWEL.

*To the Editor of THE LANCET.*

SIR,—My surprise was not a little excited, on perusing THE LANCET of Saturday last, to find an article stating that I had given opinions favourable to the employment of great force in obstetric operations. I presume that the statement originated in some misconception on the part of your reporter, as in the whole of my evidence upon the occasion of the inquest at Hampton, not one word was said upon the subject. With a view of removing from the minds of the jury the unfavourable impression made by the manner in which the witness Ann Ellam detailed the particulars of the operation, I simply asked her whether she had ever before been present at such a case, and whether she was aware what degree of force was necessary upon such an occasion; to which she replied in the negative. The principle so ably laid down by Dr. Davis with respect to the amount of force, and its being applied by degrees in the operations of midwifery, has appeared in almost every obstetric work from the first dawning of midwifery as a science, and I presume, in the present day, is strongly inculcated upon the mind of the student by every teacher of midwifery in Europe. Your giving insertion to this letter in your next week's LANCET, will oblige, Sir,

Your very obedient servant,

GEO. JEWEL.

24, Sackville Street, Piccadilly,  
Oct. 12th, 1830.

QUESTIONS TO MR. JEWEL.

*To the Editor of THE LANCET.*

SIR,—The Inquest held at Hampton before a coroner who was miserably incompetent, because not an intelligent member of the medical profession, has suggested to me the following questions, which I trust you will give me permission, through the medium of your most valuable publication, to put to Mr. Jewel, one of the medical witnesses on that very melancholy occasion.

I have the honour to be, like yourself, a friend to the cause of public justice, and

Sir, your  
CONSTANT READER.

In the state of mutilation in which the child was found upon inspection of the body of the deceased Frances Clark, how could Mr. Jewel take upon him to say, that "the only part which could have been felt during the labour had been the cheek?"

On what principle does Mr. Jewel presume the removal of the arms of the child, its mother having had a full-sized pelvis, and having previously given birth to living children at the full period of gestation, to have been "perfectly justifiable?"

Where has Mr. Jewel seen the practice in cases of cheek presentation, of "bringing down the breech with a blunt hook?" Does he teach this practice in his lectures, or has he heard of any other teacher of midwifery, either in this country, or in any other, who has ever directed or adopted it? Will he also be kind enough to refer me to any authority for the practice of "breaking the spine of the fœtus with a boot-hook, or even with a common blunt hook," in cases of presentation of the cheek?

In any case of presentation of the arms, however large the child might be, is it usual, or has it ever been recommended by a competent authority, to remove such presenting arms, by wrenching, or even by the more decorous operation of excision? If not, how came Mr. Jewel to give his opinion on oath, that the Hampton practitioner "was not to blame in the treatment he adopted?"

If the head of the child had not engaged in, nor entered deeply into, the cavity of the pelvis at the commencement of the operation, what was there to prevent the attempt of effecting the delivery by turning, an operation which, Mr. Jewel should know, consists in the bringing down of the child's feet, and not the arms, as was practised in this unfortunate case! If, on the other hand, the head, cheek or face foremost, had got down into the pelvis, and there (in consequence of the incompetency of nature to effect its expulsion, or of art its safe delivery with the forceps) had become strongly and immovably impacted, is there a com-

petently-educated practitioner in the kingdom who would not have had recourse to the operation of cephalotomy, or is there any teacher besides Mr. Jewel who could have approved of any other practice?

Having asserted on oath that the Hampton practitioner had acted properly in this case, why did Mr. Jewel decline to answer the question, whether "in the position in which he found the fœtus, he himself would have pursued the same course?"

Did Mr. Jewel ever receive instructions in the art of midwifery? If he did, it may be useful to the students of the present day to be made acquainted with the name of his teacher. If not, how could he dare to set up for a teacher himself?

It is in evidence, that the medical attendant on Frances Clark used very great force, "that he put his back against the wall, and his feet against the bed," that "something then gave way, that the sound was like a bit of stick breaking, and that both the witnesses saw a child's arm pulled off;" does Mr. Jewel still persist that the medical man who could do all this, was not to blame in the treatment he adopted? If not, he should forthwith publish an honest recantation of his error, as some small, but the only, compensation now in his power, to the cause of humanity and public justice, which he has so deeply injured.

## ST. THOMAS'S HOSPITAL.

## CLINICAL LECTURE

DELIVERED BY

DR. ELLIOTSON,

Oct. 11, 1830.

## PARALYSIS AGITANS.

GENTLEMEN,—The physician whose turn in the hospital it is on any week to make a selection of the cases which are admitted, generally takes under his own care those which are acute, and having made choice of a sufficient number to fill the vacant beds in his own wards, distributes to the other physicians the remaining cases, which are, for the most part, chronic, though now and then, as you may suppose, an acute case is amongst them. Of the medical patients admitted last Thursday under myself, six were men and six were women. Among the men is a case of shaking palsy, and another of palsy of the wrists arising from lead; one of a very curious nature,—hemiplegic palsy, in which half the body only is affected, and that only for a certain number

of hours every few days; one of periodical palsy; one of convulsions of the lower extremities on an attempt at motion, a case of anasarca and diseased liver, and one of rheumatism. Among the women is a case of hysteria, syphilis, scalled head or porrigo, chronic inflammation of the stomach, tumour of the abdomen, and inflammation of the membranes of the spine. Of these I shall select one for your consideration this morning, the case of shaking palsy, which, in medical language is called *paralysis agitans*.

The best account of this disease which I have seen, is one given by a general practitioner, now deceased, of the name of Parkinson, a highly respectable man, who wrote an essay upon the subject in 1817, from which I have derived nearly all I know upon the complaint. The subject of the present case is F— E—, a man aged 38, received into William's Ward, No. 20. The disease, according to Mr. Parkinson, consists in involuntary tremulous motions, in more or fewer of those parts of the body which are naturally under the command of the will, with diminished muscular power; and the tremulous motions occur in parts, which are not at the time in voluntary action, and even when they are supported. There is likewise a propensity to bend the head and trunk forwards, and a strong inclination, when walking, to commence a running pace, into which pace the lower limbs frequently pass from the former, the individual appearing as though in great haste, and anxious to get onwards. At the same time, the senses and intellect are quite unimpaired. The words of Mr. Parkinson in describing this disease are, "Involuntary tremulous motion, with lessened muscular power in parts not in action and even supported, with a propensity to bend the trunk forward, and to pass from a walking to a running pace, the senses and intellect being uninjured." Now this disease usually commences in some one part of the frame, as, for instance, in the head; but it more frequently begins in one hand, or in the arm; there it will sometimes remain for many months, and even for years, before it spreads, and perhaps it never spreads at all. Sometimes, however, it increases in degree and extent, and other parts become affected, until, at last, the whole body is in a constant shake. Though the tremulous motions in this disease are involuntary, yet they may be checked by an effort of the will. The effort exerted, however, must be of a powerful nature, and then it will for a few moments stop the shaking. As the disease extends, first one extremity and then another becomes affected, at length the head and trunk bend forwards, the individual walks in some measure upon his toes, the motion of walking becomes gradually quickened, at last it is

altogether lost, and the man unconsciously gets into a trot, and has all the appearance of a person in a most violent hurry. This change is owing to the disease being slightly under the will. The individual who is afflicted, finds that a powerful exertion of the muscles will stop the tremors, and as running requires more effort than walking, running answers better to control them; or we may say, that when he is walking, the same effort which he makes to check them, forces him to run, which state he continues, because he finds that he thus partly conquers the tremulous motions,—that they do not so much get the better of him and impede him. The same effect is produced in St. Vitus's dance,—a powerful effort will sometimes stop the convulsions for a moment. A curious circumstance observable in this disease is, that if it happen to remit in one part of the frame, it soon increases in another. Thus if the leg shakes more, the arm may shake less; and so remarkable is this, that if you take hold of the arm, for instance, and prevent it from shaking, the leg will begin to tremble immediately; if you steady one part, the other is sure to shake more violently, or perhaps begin to shake, though quiet previously. This also is often observed in St. Vitus's dance. It sometimes happens, that a change of posture will arrest the trembling in the part. The disease agrees in another respect with *chorea*, or St. Vitus's dance, that the shaking ceases during sleep, though when very strong indeed, the shaking continues, whether the patient be asleep or awake,—a circumstance also occurring in violent cases of *chorea*.

In the usual progress of *paralysis agitans*, the voice is not affected until the muscles of the upper extremity and head have been so for a long time. At last, however, speech becomes involved, and the muscles employed in the acts of deglutition and mastication are affected, and speaking, chewing, and swallowing, are extremely difficult to be performed. By and by the urine and fæces pass away involuntarily, general emaciation ensues, entire decay of the powers, and ultimately death. Such is the melancholy progress of the disease when it continues to extend beyond the part originally affected, though frequently it does not increase at all. You may often see persons with the head constantly shaking, while no other part is affected, and in whom the disease has existed to the same degree and extent for many years. Sometimes, also, you may observe persons, one of whose hands only is, for many years, agitated. Mr. Parkinson relates a curious case in which there was also hemiplegia, but one only of the two diseases was present at a time, for when the hemiplegia commenced in the agitated parts,

the shaking ceased; and on the cessation of the hemiplegia, the shaking recommenced.

This disease is to be carefully distinguished from the tremulous motions with which drunkards are affected. It is entirely distinct from the effect produced by habitual intoxication. You are well aware of the effects which spirituous and vinous liquors, tobacco, tea, coffee, and other narcotics, will produce when used in excess. If the indulgence in any of these is habitual, then the shaking is continuous, and it is only by discontinuing their use that the tremours cease. This trembling, too, will be produced temporarily by occasional strong doses only. It generally, also, affects both hands, and is seen chiefly when any effort is made by the individual; if, for instance, a pen is taken in the hand, a shaking comes on the moment an attempt is made to write; or if a cup or glass be lifted, the contents are spilled over. The greater, too, the effort which is made, the more excessive is the tremour that follows. But in paralysis agitans exactly the reverse of this is observable, for a strong effort will, for the time, overcome the disease. By this, and by the affection occurring pretty equally in both hands, you may distinguish nervous trembling from paralysis agitans. You are aware that strong passions, as fear and rage, will also, like strong tea, coffee, or tobacco, produce a trembling,

It does not appear that the disease of which I am at present speaking, was well characterised or distinguished before Mr. Parkinson wrote on the subject. The peculiar characters which mark the shaking of drunkards, as different from the diseases of muscular agitation, had been pointed out by Galen, and many others since his time, but paralysis agitans was not well defined before the essay of Mr. Parkinson. Having then described to you the usual course of the disease, I shall revert to the particular case before us.

The patient, F. E., is 38 years of age, and has had the disease eighteen months. He has been accustomed to drink hard at different periods of his life. He is a school-master by profession. It is the right upper extremity which is now affected; but though the right lower extremity is not in agitation, it is occasionally retracted as he walks,—experiences solitary catchings, though it does not shake. The disease began in the head and tongue, but when the right upper extremity was affected, it left the head. This peculiarity distinguishes the present case, that the tongue is one of the parts that were first affected. In general this is not the case, and the tongue is not affected, after many other parts have suffered severely. The head now shakes very slightly only. The affection of the tongue is at-

tended by the following very curious result. Whenever the man attempts to speak, the tongue begins to quiver like the tongue of a serpent; presently a confused murmur is heard, and then suddenly he brings out his words with extreme rapidity; and such is the effort that he cannot stop himself, but repeats the few last words again and again. It is a phenomenon analogous to the running which occurs on the attempt to walk. He cannot manage the muscles at all, without a violent effort, such an effort that his tongue gets as it were into a run; the common expression of the tongue running, when we describe a person who makes a good use of it, is really applicable to this patient. I have written down in the case-book, "Before he can speak he makes a confused and inarticulate murmur, and then speaks rapidly, slurring his words together, and repeating the last words several times. The effort makes the tongue and right upper extremity shake violently." He sleeps very well, his appetite is good, and in all other respects, except this shaking of the body, he is in tolerable health. Sometimes after a good night's rest he does not shake at all for a few minutes after waking in the morning, but then it is not long before the trembling commences. Any excitement or attempt to do any thing at once, greatly increases the tremours, but by a strong effort he can at length arrest them for a few moments. The only other symptom present is costiveness (he has but two stools a week), and a pain in the head whenever he is anxious.

With regard to the nature of the disease, in many cases it depends, no doubt, on organic affection of some kind. Mr. Parkinson gives a dissection after the disease, in which the lingual and brachial nerves were found indurated, and the medulla oblongata very firm.

When patients get from bad to worse, and nothing whatever makes an impression on the disease, it is impossible to avoid supposing that an organic change has taken place in the nerves of motion, the medulla spinalis, or the medulla oblongata. In many cases the disease is controllable by art; it ceases on active treatment. In young persons I have often seen it cured. In such cases there has always been great costiveness. In old persons I have not remarked this, and the disease is most remediable in young persons, in whom it usually arises, in all probability, from mere congestion or inflammation, or some state of the nervous matter of a peculiar nature, not understood, but independent of organic change or inflammatory action.

As to the cause in this man, it is not very certain. It appears that about two years ago he had a fall, by which his head was slightly contused; but it is impossible to say

whether this has had any share in producing the present disease. This circumstance is very likely to have had some effect at a subsequent distant period; for it is quite surprising how often medical men see organic changes or chronic inflammation produced, and especially in the head, by a very little accident that happened at a long period previously. Eighteen months ago, too, he informs me he was mercurialized. He has also suffered great anxiety. The fall might have produced it; indulgence in drinking, anxiety, and the effect of strong mercurial action, may have all co-operated. From the circumstance of the disease having followed a fall, I should be less sanguine in my prognosis, as chronic inflammation and induration, or other changes of structure, may have been produced.

As regards the treatment in a case of this kind, if I ascertain that there is any inflammatory state, or fullness of the head, I employ bleeding generally or locally, or both, setons, issues, moxas, and also purging and low diet, and mercury. If there is mere fullness of habit, I should employ antiphlogistic measures. But if there is no reason to suppose that any fullness or inflammation exists,—if the patient is not of a plethoric habit, if no local pain or tenderness is felt, then remedies which exert a peculiar action on the nervous system, different altogether from that of narcotics, are the best means. Almost all nervous disorders whatever, and convulsions of various kinds, may arise from inflammation, from fullness, congestion, or a peculiar condition, the nature of which we do not understand, but which we do not consider to be necessarily inflammatory. I do not know how to distinguish between the propriety of adopting either of the two modes of treatment, but by observing whether there be fullness of habit or not, local heat or pain, and whether there has been a local cause—an external injury. When there is nothing of this sort observable, then stimulants and tonics, and those peculiar medicines, are the most useful things you can employ. Iron, nitrate of silver, arsenic, sulphate of zinc, and preparations of copper, are in this class, and frequently do great good in all kinds of nervous cases, though we do not know how. As to this man, he has been both in St. George's and the Middlesex Hospitals before coming here, and in both he was very properly, though unsuccessfully, treated. What was done in St. George's I may as well inform you. He was bled and cupped; counter-irritation by blisters was employed, a discharge was kept up from the back of his head, and he was put upon a low diet,—a plan which it was very reasonable to pursue in the first instance, for he is in the prime of life, of rather full habit, and had suffered a mechanical

injury. I found, likewise, that in the Middlesex Hospital, stimulants were subsequently allowed him; he had porter and camphor, and good nourishment, as the previous plan had failed; and though not cured by this treatment, he was rather better. Judging from these facts, I have determined to support him well, and exhibit tonics and those remedies which peculiarly control some diseases of the nervous system. Had I seen him long ago, I should have begun with the plan followed in St. George's, and after a full trial, and failure, had recourse to the method pursued at the Middlesex. The present state of the man induces me to follow up the latter plan. Among the various remedies of the kind now spoken of, iron is one of the most powerful, and certainly the safest. I have been more successful with this medicine than any other in nervous affections, and it is safer than arsenic, and does not irritate the stomach and bowels as arsenic and copper do; it is pleasanter than nitrate of silver, for it occasions no risk of blackening the skin. I have accordingly ordered two drachms of the subcarbonate of iron, to be taken three times. He informs me he is always better when stronger, and better with a certain allowance of porter, and I believe him, both because the strengthening plan frequently does answer much better, and because he is a respectable man, apparently very anxious to get well. I need hardly say how necessary it is to attend to the state of the bowels. Whenever there is any approach to inflammation, or congestion in the nervous system, purging is sure to effect good; and nervous diseases may sometimes arise from torpor of the bowels. Altogether, however, I have been disappointed in the use of purgatives in chronic disorders of the nervous system as curative, or materially mitigating remedies; but on account of the costiveness in this man's case, I have ordered the croton oil every day, in order to keep the bowels open; for though purging might do no positive good, and by debilitating might in this case increase the morbid irritability of the nervous system, yet constipation would certainly do harm. Also the iron, being a bulky medicine, would accumulate if costiveness were permitted, and prove troublesome. Generally speaking, if given with treacle, the composition has a tendency to open the bowels, and no aperients are required. But costiveness should always be carefully avoided when it is exhibited.

It is not very often that we have a case of this disease in the hospital; but I have cured many in private practice; in young persons, by bleeding, cupping and leeching the head, and by purgatives. I had, however, one in the hospital, in which all these were perseveringly employed,—I cannot say

how long or often,—and in which subsequently I gave sulphate of zinc in large quantities, all without effect; but on having recourse to iron, the disease instantly and permanently gave way. Iron here certainly acted specifically, and yet I may mention that the head was hot and painful. Still I have prescribed it as well as all the other remedies of that kind, and all the remedies of chronic inflammation, in many cases of elderly persons, who derived not the least advantage from the treatment, and most probably because there was organic disease,—some change of structure in the nerves of motion, and those parts of the brain and medulla, with which they are immediately connected.

#### DISEASE OF THE HEART.

Before we separate I have a few observations to make on a very interesting case of disease of the heart which has just proved fatal, and the morbid changes of which I have now before me. The patient was a young man admitted into the hospital on the 8th of July last, William's Ward, F. S., No. 4, aged 25. The history of the disease was this:—he had been ill between three and four months with ague, which, he said, had begun two days after arriving, on the 31st of March, at a place called Figuera, which is four days' sail from Lisbon. He said that he had a paroxysm generally every day, and rheumatic pains in the limbs during wet weather. Let me observe to you, while on this subject, that there is nothing more common than a combination of ague and rheumatism in the same individual. Sometimes they co-exist, sometimes they alternate,—curiously enough, the ague ceases when the rheumatic pains commence, and when the rheumatic attacks are over the ague comes on again. We cannot see any connexion between the two diseases to produce this, but so it is. In the present case I observed a swelling of the lower extremities, which were always very cold. There was also tenderness of the abdomen, especially in the region of the umbilicus, and on the right side of the chest. It is common enough for the abdominal viscera to become diseased, and dropsy of the abdomen, or general dropsy of the body at large, to occur with, and subsequently to, ague. The dropsy in this case was shown by soft, pale swellings of the legs, pitting upon pressure; and the tenderness all over the abdomen, without manifest disturbance of the functions of any of the abdominal viscera, showed more or less of inflammatory affection of the peritoneum. The fulness also of the abdomen probably arose partly from ascites, though there was not sufficient fluid to occasion fluctuation. The pulse was sharp and

strong, and beating 104. This fact, with a little difficulty of breathing, led me to suppose that the heart was affected, for there was evidently no inflammatory disease sufficient to account for the state of the pulse. There was no feverishness of body. He had dyspnoea certainly on lying down, and quick motion, but hardly any cough; and there was nothing in the mode of breathing to lead to a belief that the lungs were affected. I applied the stethoscope. The action of the ventricles of the heart was morbidly strong, particularly in the left region of the organ, and extended over a considerable space. A bellows sound could be very plainly heard on that side, and in a lower degree indeed to some extent. Now ague itself is generally cured with the sulphate of quinine, but here the tenderness of the abdomen, the state of the pulse, and the force of the heart, led me to have recourse also to bleeding. The ague was presently cured by five grains of the sulphate of quinine three times a day. A pint of blood was also taken from the arm, and I gave him two grains of calomel twice a day, and put him, of course, on a low diet. He was, in the progress of his treatment, continually cupped and bled by leeches over the region of the heart and abdomen. He shortly got, as he considered, much better, and wished to leave the hospital, and return to his occupation; but however much his health might be improved in other respects, the state of the pulse, and the force and sound of the heart, led me to advise him to remain. He soon after became dropsical again and died, the pulse being, to the day of his death, nearly as sharp as it was at first. On the post-mortem examination, I ascertained that a most important disease of the heart had existed, and this I will now show you. First of all, both ventricles are dilated, and I should observe, that when this happens, the heart acquires a very considerable size, and becomes nearly round at the apex, the angle of the apex becoming so obtuse that the apex is really almost effaced; this alteration in the heart may be seen in the plate before you. (Plate VI. of Dr. Elliotson's work on Diseases of the Heart.) There is exactly the same appearance in this heart (showing it) as in the engraving. Observe here that the left ventricle is considerably increased in size. The right is larger than usual, but not so large in proportion as the left. The heart itself, notwithstanding its great dilatation, is at least of its natural thickness; indeed, the walls of the left ventricle are more than that,—it has lost nothing in thickness by its enlargement in capacity. There must, consequently, have been a great addition of substance made to it, or it would have become thinner. This thickening and dilatation together of

the heart is called *eccentric hypertrophy*. We shall, in the course of the winter, see instances decidedly the reverse of this, where the cavity of the hypertrophied walls is diminished; and those are distinguished by the term *concentric hypertrophy*. I told you that there was a strong bellows sound heard in this case; I will now, therefore, show you in the same heart a most remarkable specimen of disease of the valves of the aorta—an extraordinary growth like venereal warts. I do not recollect having ever seen excrescences of such a length as are here, one is nearly an inch and a half long. There are excrescences from each valve of the aorta. Now these did not present much impediment to the circulation; they are quite soft and flat, and not greatly in the way of the course of the blood, and we need not, therefore, wonder that the pulse was sharp and really very full to the last. Taking into consideration the size of the left ventricle and its thickness, the muscular force which propels the blood into the aorta must have been immense. The inconvenience which the patient must have suffered from the violence it exerted must have been very great. Though there was no material impediment to the circulation from the excrescences, yet examination by the ear sufficiently showed, by the strong bellows sound, the existence of impediment. In this other plate there is a view of excrescences proceeding from the valves, of a globular form, and another of excrescences with minute growths of bone. To show you how little disease of the heart may be suspected in a case of this kind, without the intervention of the ear, I may mention, that in one of these cases, the man was admitted into the hospital for some other disease, and he neither complained of, nor appeared to suffer from, any affection of the heart, and we were not a little surprised, on examination after death, to discover the excrescence. Probably, if there had been any reason for listening in that region, we should have found a bellows sound. In the present case I did examine by the ear, and discovered impediment. I have no doubt, that the minutest impediment is sufficient to produce the bellows sound. In the present case there was general dropsy, tenderness of the abdomen, slight chronic peritonitis, slight difficulty of breathing; and on striking with the hand over the region of the heart, a dull sound to a great extent was perceptible. On opening the pericardium, about half a pint of perfectly clear serum was found, with a few flakes of lymph. Fluid also existed in one pleura. The heart had become so large, that it had distended the pericardium greatly, and there was, in consequence, little room for any effusion; but what space there was, was entirely filled

with this serum. The flakes of lymph were probably the result of inflammation of the pericardium, connected with his rheumatism. In the course of the winter I shall give you reason to suppose, that hypertrophy of the heart is generally the result of an inflammatory affection, when not of mere impediment; and that most inflammatory affections of the substance of the heart and the lining membrane, begin with, or arise subsequently to, more or less inflammation of the pericardium.

## ST. BARTHOLOMEW'S HOSPITAL.

### FRACTURE AND AMPUTATION OF THE FINGER.

JOHN FROST, æt. 33, was admitted into Colston's Ward on the 22d of September, with a severe wound of the middle-finger of the left hand, occasioned by the fall of a heavy piece of timber. The second phalanx was fractured, the soft parts were much lacerated, and the periosteum was denuded to some extent. In consequence of the exceedingly contused state of the parts, amputation was deemed advisable, and was accordingly performed in a particularly neat manner by the dresser, Mr. Bullmore. The incision was commenced about an inch from the phalangeal extremity of the metacarpal bone, and carried forwards on each side. The metacarpal bone was then divided in a transverse direction to facilitate the contact of the severed edges, and the remaining fingers were brought together by means of a small roller.

The wound has now nearly healed. There is very little deformity, and it is to be hoped that the utility of the hand is but slightly diminished.

We notice this case chiefly for two reasons; first, to show the pupils the little deformity of the hand that arises from the amputation of a finger through the metacarpal bone, and, secondly, for the purpose of bestowing on a scientific and zealous dresser that approval of his conduct which it certainly deserves.

### EXTENSIVE DISEASE OF THE ANCLE-JOINT— AMPUTATION OF THE LEG.

J. REEVE, æt. circ. 30, admitted into Darker's Ward on Sept. 30. The left ancle-joint was much enlarged, and on each side there were fistulous openings, from which a considerable quantity of matter was continually discharged.

The patient says that he was in this hospital with disease of the same joint about six years ago. He is a newsman, and he imagines that the continual walking to which he was subjected was the cause of this

second attack, which made its first appearance about two years since. A twelvemonth ago discharges of matter took place, and these continued until his admission into the hospital. The foot has become œdematous, and his general health seems much impaired.

On Saturday last Mr. Vincent amputated the leg below the knee by the double flap operation. Little hæmorrhage occurred, the vessels were quickly secured, and a neat stump was formed.

The patient, since the operation, has been doing well. Tongue clean; pulse natural.

At the conclusion of his Saturday's lecture, Mr. Stanley produced the amputated leg, and made a few remarks, which we here insert:—

“With regard to the *duration* of this disease, Gentlemen, I know nothing; but looking at the condition of the limb, I should be led to infer that it was of some standing, perhaps twelve or eighteen months. The disease is obviously seated in the ankle-joint, but it is a question whether it originated in the bone, or the soft parts. That it was not in the *bone* I may pretty safely affirm, because diseases commencing in the bone in affections of the joints, are of exceedingly rare occurrence. You observe these abscesses on either side of the limb; it is most probable that the matter having formed within the capsule, ulceration took place, and it found vent through these openings, which have been filled with unhealthy spongy granulations. (Here the lecturer commenced the dissection.) Look, Gentlemen, at the excessive thickening of the soft parts, and observe the enlargement of the cellular tissue. Now we come to the joint—or rather, I should say, that of the *joint* there is scarcely a vestige left. You observe that the cartilages of the ends of the bones are completely destroyed; the bone is rather soft, and there are granulations on the surface of the astragalus, so that had the limb remained attached some time longer, bony matter would have been thrown out, and complete bony ankylosis would have taken place. This is the only process we could anticipate. Next let us look to the commencement of the disorder. What is its essential character? Did it originate in common inflammation, or are these to be regarded as the effects of scrofula? Where the disease began, of course we cannot determine, but most probably in the synovial membrane, since that is the point of attack in the majority of cases of inflammation of the joints. But has any change occurred in the structure of the bones? We find it soft—a little softer than natural. If, however, the affection were of a scrofulous character, we should find soft matter in the middle of the bones, which is not here the case. Here

then we have the capsule ulcerated, the bone soft and ulcerated also, and the cartilages completely destroyed.

## WESTMINSTER HOSPITAL.

### PLEURITIS.

JAMES RACKHAM, ætat. 19, admitted 26th Sept. 1830, with pleuritic symptoms, which had existed four days; he suffered from a violent cough, with pain of right side over the short ribs, increased on each inspiration.

*V. S. ad deliquium.*

*Bolus calom. et antim. mist. diaphoret. 6tis horis.*

27. Ten ounces of blood were abstracted, much buffed. Respiration more frequent, 40 per minute; acute pain on pressure in the short ribs; tongue furred; occasional cough, inducing acute pain across the chest; pulse 86, feeble, undulating; bowels open.

*Mist. diaphoret. c. c. tempor. ad 3x.*

This man was subject to epileptic fits; was exposed to cold a few days since, which seems to have brought on this attack

*Emplast. lyttæ lateri.*

Sept. 28. Six ounces of blood taken away, a blister afterwards applied, which has risen well; breathes much more easily; countenance tranquil. Pulse 70, soft; tongue clean in its circumference; bowels open; slight cough; expectorates mucus.

*Emplast. lyttæ lateri.*

29. Continues to improve; a feeling of constriction across the thorax, but to a less degree than yesterday. Cough, not much expectoration.

30. All the symptoms alleviated; functions natural.

Oct. 1. Tongue still furred; bowels open; cough frequent, and producing pain in the lower part of the right side of the thorax; pulse 75, soft, full.

*Rep. mist. diaphoret.*

3. Considerably better; slight cough, but producing uneasiness on the right side, the old seat of pain; tongue much cleaner; pulse quick; bowels free.

*Bolus calomel : haust. purgans.*

5. A slight relapse; breathing labours; pain of side augmented by coughing, which is frequent; expectorates little; difficulty of swallowing; internal fauces swollen; tongue furred; shiverings alternating with flushings; skin hot; bowels scantily open; headache; eyes dull; countenance heavy.

*V. S. ad 3viii;*

*Bolus calomel et antim statim, et haust. purgans 2da hora postea.*

Respiration *puerile* on the left side of the thorax, dull on the right, and on the lower part a slight *râle crepitant*.

7. No buff on the blood, countenance natural; cyanche increased; no pain in any part, not even on a full inspiration; cough is frequent, and he expectorates a frothy and mucous secretion; respiration quite natural; cough excites a little uneasiness on right side; tongue furred, but clean round the edges; pulse about 90.

*Gargarrisma commune.*

9. Convalescent.

### HOPITAL ST. ANTOINE.

#### AMPUTATION OF THE RIGHT THIGH—TORSION OF THE ARTERIES.

D., *âgé* 15, was admitted on the 16th of September, 1829, with white swelling of the right knee, in consequence of a fall. Leeches, blisters, and moxas, had been applied, but without any success; and on her admission the diseased knee was three times as large as the other; the skin over it was much distended, and at the outer side there were two superficial ulcers; the tumour was very firm, fluctuating, and extremely painful on pressure, or the least movement of the limb. The patient's general health was much affected; she was emaciated, feverish, restless at night, &c. After having watched the case for some days, M. Velpeau decided on performing the amputation of the thigh. On Sept. 21st, in order to obtain the immediate re-union of the wound, two lateral flaps were formed, and hæmorrhage was arrested by the torsion of the arteries. On the femoral and two smaller vessels, this method was applied with success; on a fourth however it failed, so that it was necessary to apply a ligature. The wound was carefully dressed, and a *tourniquet d'attente* applied to the upper part of the thigh. No secondary hæmorrhage occurred. On the 24th the dressings were removed for the first time; the stump looked very well, but was rather tender and irritable. On the night of the 25th the patient was seized with vomiting and colic pain, the cause of which could not be ascertained. The wound began to suppurate in some places; there was much fever and slight diarrhœa. On the 20th she had an attack of shivering, followed by high fever, delirium, and great restlessness during the night. On removal of the bandage on the 27th, the bone was found protruding an inch from the wound, a small part of which only had united; it discharged a very large quantity of purulent matter, which, during the following days, became of an unhealthy kind, and was accompanied by a typhoid

state, discoloration of the skin, &c. The patient died on the 4th of October, after a long and painful struggle. On examination the bone was found denuded to an extent of three inches; the muscles, at the external side of the thigh, had a large quantity of matter between their interstices, almost as high up as the great trochanter. The hip-joint was also filled with pus, but without any morbid alteration of the articular surfaces. The coats of the femoral vessels did not exhibit any trace of inflammation, but the vein contained a large quantity of semi-coagulated blood, mixed with a greyish puriform substance. The lungs were filled with small tubercles.—*Journ. Hebdom.*

In a former Number of THE LANCET a similar case was related, in which, instead of the ligatures, torsion was applied with nearly the same effect as in the one above; hæmorrhage also occurred, though to a small extent; but the only assignable cause of the fatal termination, was a large deposition of matter between the muscles of the limb.

#### AMPUTATION OF THE LEG AT THE KNEE-JOINT.

In our last Number we alluded to a paper of M. Velpeau, which he read on the above subject, and mentioned the cases observed by him, in which the operation terminated successfully. We have since received a more detailed account of one of the cases, a more accurate description of which will, perhaps, be read with interest.

In January last a young man, 19 years of age, was admitted under the following circumstances:—Six years ago he had sprained his right foot, and having neglected the injury and continued his usual occupation, swelling of the ankle acceded, accompanied by violent throbbing pain, which altogether prevented him from walking. The leg gradually increased in size, and at its inferior portion ten or twelve abscesses formed, which opened and discharged a great quantity of matter and pieces of bone, and left a number of sinuses; the tibio-tarsal articulation continued in a state of chronic inflammation, and the patient had, for the last three years, been entirely deprived of the use of the limb. His general health was, however, not affected. The disease did not appear, after close examination, to extend to the knee, and M. Velpeau accordingly decided on amputation of the leg immediately below the joint. The operation was performed on the 14th of January. A circular incision having been made through the skin and muscles the tibia was laid bare,

but being found to be diseased and denuded of its periosteum, the operator was placed between the alternative of performing the amputation of the thigh or exarticulation at the knee-joint; and as by the circular incision part of the latter operation had already been performed, he, without much hesitation, decided on completing it according to Sabatier's method. An anterior flap was formed, containing the patella, and a posterior one, with the popliteal vessels. The articular surfaces were quite healthy; ligatures were applied to the popliteal and articular arteries. The posterior flap, which is almost exclusively destined to cover the stump, was unfortunately rather small, in consequence of the circular incision at the commencement of the operation, and could not be made to cover the wound or to meet the anterior one, though it was of course brought as near to it as possible. The wound was simply dressed with lint and cerate, and a circular bandage was applied round the thigh. The dissection of the removed leg was rather interesting; the tibia was very much enlarged, of considerable weight, and almost ivory hardness; the upper three-fourths of its medullary canal were completely obliterated; the inferior portion necrotic, carious, and filled with purulent matter, which communicated with the fistulous openings; the astragalus, tibia, and fibula, were completely ankylosed; the periosteum of the tibia was much thickened and changed into a whitish cartilaginous mass, and for the greater part separated from the bone.

On the second and third day after the operation, the patient complained of much pain in the stump; his general state was very good, and there was hardly any fever. On the 17th the bandage was removed for the first time; the wound was of a greyish-red colour; the cartilages began to lose their natural smoothness. The 18th passed without any unfavourable symptom. On the 19th, the pain in the stump, though not so great as before, extended up the thigh and hypogastrium; the tongue was coated, the pulse rather feverish, and the patient complained of restlessness at night; his bowels were rather costive. Both flaps, but the posterior in particular, were swelled; granulations of healthy appearance were beginning to shoot up from the wound. After an emollient glyster, all unfavourable symptoms disappeared; and on the 21st the patient was so entirely free from pain in the stump, that the flaps could be brought nearer to each other. On the 23d some ligatures came away; granulation continued to be of a healthy kind; the cartilaginous surfaces exhibited in some places a greyish brown colour. On the 26th, the interval between the flaps did not exceed an inch, and was

rapidly filling up; all the ligatures had come away. On the 4th of February, the interval between the flaps had further decreased. Adhesion began to take place on numerous points, and on the 18th it was completed, and the cicatrization proceeded rapidly. During the following days the wound began to assume rather a torpid appearance, and required the repeated use of the nitrate of silver. At the same period, two or three small abscesses formed at the side of the stump, and after having been opened, left some fistulous ulcers, which within a short time spontaneously healed. At the beginning of April cicatrization was completed; the patella was immovable, and did not cause any impediment to the application of a wooden leg.

### HOPITAL DE LA CHARITE.

#### HOSPITAL GANGRENE.

In a lecture which M. Roux lately gave on gun-shot wounds, he mentioned the extreme rarity of the above affection, compared with what was observed in former times. Since 1814, he has observed it only three or four times at the Charité, and as these cases occurred in patients occupying the two corner-beds of one of his wards, it occurred to him, that a fountain in the wall between them might be the cause of this singularity. He accordingly ordered the fountain to be removed, and since that time, no other instance of hospital gangrene has been observed there.—*Lanc. Franç.*

### LITERARY INTELLIGENCE.

An "Encyclopædia of Practical Medicine," comprising Treatises on the Nature and Treatment of Diseases, including Pathological Anatomy, and such parts of Materia Medica and Medical Jurisprudence as are of a more strictly practical character, is preparing for publication in London. The following gentlemen are amongst the contributors whose assistance has been secured:—Drs. Carswell (Paris), James Clark, Conolly, D. D. Davis, Darwall (Birmingham), Forbes (Chichester), George Gregory, Marshall Hall, Roget, A. T. Thomson, Alexander Tweedie, Barlow (Bath), and Prichard (Bristol). It is to be published in parts, royal 8vo, with double columns, to form a volume of 1800 pages when complete.

An Address Introductory to a Course of Lectures on the Principles and Practice of Physic, by Mr. James Baker, has been published at the request of the Members of the City of London Medical and Chirurgical Society.

## BOOKS FOR REVIEW.

The Journal of a Naturalist. Third edition. London, John Murray, 1830. pp. 440.

The Laws relating to the Medical Profession, with an account of the Rise and Progress of its various Orders. By J. W. Willcock, Esq., Barrister at Law. London, J. and W. T. Clarke, 1830. 8vo. pp. 449.

A Treatise on Poisons in relation to Medical Jurisprudence, Physiology, and the Practice of Physic. By Robert Christison, M.D., &c. Edinburgh: Black. 1829. 8vo. pp. 698.

The Principles of Forensic Medicine, systematically arranged, and applied to British Practice. By John Gordon Smith, M.D., &c. Third Edition. London: Underwood. 1827.

A Treatise on the Natural and Chemical Properties of Water, and on various British Mineral Waters. By Abraham Booth, Op. Chemist, &c. London, G. Wightman, 1830. pp. 196.

An Account of the Trial between J. Stancliffe, Plaintiff, and T. Chorley and G. Bulmer, Defendants, for neglect and inattention in the Dislocation of an Arm; tried July 31st, 1830, at York. Leeds, 1830, pp. 61.

An Introductory Address, delivered at the Belfast Mechanics' Institution. By Henry M'Cormac, M.D. London. Longman. 1830. pp. 24.

Lithographic Representations of an Invalid Carriage, constructed on a new and improved principle, for the express purpose of conveying patients to and from hospitals, &c., with as little pain, inconvenience, or delay, as possible. G. Morton, inventor. Engelmann and Co.

Description of the Pettrisseur or Dough-kneading Machine;—an apparatus for making bread by machinery. J. Clements. 1830.

## TO CORRESPONDENTS.

*A Mutual Friend.* The accusation concerning the "mean act" was not directed against the *Medico-Chirurgical Review*. Dr. Johnson acted a most honourable and manly part in the case of Miss Cashin, and we shall not apply the torch of discord to the olive-branch of peace. Dr. J., probably, is not the only editor who has discovered that

"party is the madness of many for the gain of a few."

The letter of *Mr. Wharton* reached us too late for our present number. It shall appear next week.

The suggestion of *A Constant Reader, Norwich*, is one upon which we cannot act, and if it were practicable we fear it would be unsightly.

*F.* A great number of the coroners of England, including those of Norfolk, Suffolk, and Essex, petitioned parliament about four or five years since, for an increase of fees. The prayer of the petition was not complied with, but there is certainly no body of men in the kingdom whose services, if adequate to the duties of the office, are so ill rewarded. Mr. Edward Clarkson, about the time that the petition was presented, quoted some of the articles in *THE LANCET* into the *Sunday Times*, and was one of the first public writers who acknowledged and insisted upon the validity and force of the arguments which from time to time we had employed in the pages of this Journal.

We may state generally that the Dublin schools of medicine possess great merit. A person on the spot, by making the proper inquiries, can easily discover the best of them. As we are not personally acquainted with any of the hospitals or schools of Dublin, it would be invidious to attempt to institute comparisons in this place with the, probably, deficient information we possess.

The publication of the letter of a *Constant Reader* relative to the inquest reported in the *Hampshire Telegraph*, would subject us to an action for libel.

The supposed occurrence which appears to have given *M. H.*, so much "horror," is a physical impossibility.

The "uncivil, sneering, contemptuous," conduct of a certain secretary complained of by *A Medical Student*, cannot be noticed unless the letter of our correspondent be properly authenticated. We cannot, indeed we will not, attack the characters of public officers, merely upon the authority of anonymous writers, or, rather, upon no authority at all.

We have received a great number of communications respecting St. John Long, but we cannot use them, nor pass any opinion upon them, until he has been either acquitted or condemned in a court of justice. Let not this notice, however, deter other correspondents from transmitting communications relating to this individual, because they may ultimately prove useful to ourselves, and advantageous to the public.

ERRATUM:—Page 95, for Roy. *Western* Ophth. Hosp., read Roy. *Westminster* Ophth. Hosp.

## DEATH OF MR. HUSKISSON.

THE CASE OF THE LATE MR. HUSKISSON,  
DRAWN UP BY HIS SURGICAL ATTENDANT,  
MR. WHATTON.

*To the Editor of THE LANCET.*

SIR,—I observe, in your publication of Saturday, Oct. 9, a letter from a Doctor Wetherill of Liverpool, animadverting, in no measured terms, on the surgical treatment of the late Mr. Huskisson, to which I think it quite necessary to reply. Several anonymous observations on this subject, indeed, have appeared in the public prints, drawn up from erroneous information, and concluded upon principles entirely inconsistent, and at variance with the plain facts of the case; but this was perhaps to be expected, on the occurrence of an accident, like the one in question, to an individual of the rank and talents of Mr. Huskisson, and the very circumstance of their being anonymous was, in my opinion, sufficient to preclude the necessity of any reply. When, however, a sweeping and unqualified charge of ignorance and imbecility is openly brought against the surgical attendants who were entrusted with the case, and when that charge is authenticated by the genuine signature of a physician of Liverpool, and declared to be confirmed by the "*general opinion of the faculty there*," the matter assumes a very different complexion, and it becomes highly proper, for the satisfaction of the public mind, that some further notice should be taken of it, and that the profession should be put in possession of the facts of the case, in order to enable them to judge correctly of the merits of the question.

Mr. Huskisson received a compound fracture of the leg and thigh, on the 15th of Sept. last; both bones of the leg were broken at the upper third, and much comminuted; their splintered ends exposed, and the soft parts lacerated to a considerable extent; the femur was fractured somewhat above its middle, and both ends exposed; there was here also much comminution, and an extensive laceration of the muscles and integuments,

and the femoral vessels were distinctly visible at the bottom of the wound. As the accident happened midway between Manchester and Liverpool, considerable delay took place before one of the carriages could be detached from the train, and the necessary arrangements effected; but as soon as this could be done, Mr. Huskisson was carried forwards to the vicarage at Eccles, and the same engine passed on to Manchester for surgical assistance.

Mr. Ransome, Mr. Garside, Mr. White, and myself, were on the rail-road when the engine arrived; and having learnt the particulars of the accident from Lord Wilton, who came up from Eccles, the necessary instruments for amputation were procured from Manchester, and we set off as quickly as possible for the vicarage, where we arrived at about half past two o'clock, two hours after the accident.

Mr. Ransome and myself were introduced by Lord Wilton, and found that Dr. Brandreth of Liverpool, and Dr. Hunter of Edinburgh, who had accompanied the procession, had arrived in the carriage with Mr. Huskisson, and had remained in attendance upon him from the period of the injury.

The patient was laid on a sofa; there had been great hæmorrhage, not only on the receipt of the wound, but afterwards, by constant draining from the veins; countenance pale and ghastly, forehead covered with cold perspiration, cold and stiffened extremities, and sickness and oppression at the stomach, with frequent convulsive shudders, difficult respiration, and great constitutional alarm.

Although an immediate amputation was every way desirable, yet, to have operated under these circumstances, would have been madness in the surgeon, and certain death to the patient. Small quantities of warm cordials were given at intervals as the stomach would bear them, bottles of hot water were applied to the hands, feet, and sides of the chest, and every thing was had recourse to, with the view of calming the constitutional disturbance, and of restoring some little power, to enable him to endure the additional shock of the operation.

These efforts were in vain. The anxiety and oppression still remained, the pulse

fluttered occasionally at the bend of the arm, the difficulty of breathing increased, the convulsions became gradually more violent, and we witnessed his departure, with feelings of the deepest sympathy and regret, at 9 o'clock, 8½ hours after the accident.

Dr. Wetherill, in arguing upon this case, has suffered his decision completely to precede his judgment; he has gathered his information from the hearsay of any person who has felt inclined to gossip with him, and, when he has thought himself sufficiently furnished, has straightway indited a letter upon a case which he never saw, and drawn his conclusions from premises which never existed.

He says "it is the opinion of the faculty in Liverpool, that the treatment of the case was *unscientific, inefficient, and imbecile*;" I do not believe him. I do not believe the faculty of Liverpool are in the habit of acting so inconsistently, as to give a public, unqualified, censure on a case which they have not witnessed; nor do I think, from the knowledge I have of some of them, that they are at all likely to do so, from any additional light which Dr. Wetherill may think he has thrown upon the subject, by his letter of the 27th of September.

The Doctor says, that "an army or a navy surgeon might have saved the life of Mr. Huskisson, and so might any other surgeon, whose head and hands knew how and when to do their duty." Sir, I take leave to say that Mr. Ransome, my colleague in attendance upon this case, has been for the last five-and-twenty years one of the surgeons of a general infirmary, which, for extent of practice, and for surgical talent, may vie with any in the united kingdom; and I believe him to be as respectable, as sound, and as able a practitioner as any in the country. For myself I have merely to say, that as Dr. Wetherill so poignantly laments the absence of naval or military experience in this case, it may soften his distress to be informed that I was bred in the army, and that, in the Peninsular Campaign, I have witnessed the practice of many of the first military surgeons of the day; and I can assure him that not one of them would have ventured upon an operation, where the chances were so decidedly against its success; but, instead of inflicting an additional injury, would have waited until the patient had somewhat recovered from the great constitutional derangement incident on such an accident, and had shown, at least, some hope of outliving the operation.

I shall quote a short passage or two on the question of immediate amputation from Mr. Guthrie. At page 24, he says, "If a soldier, at the end of two, four, or six hours after the injury, have recovered from the general constitutional alarm occasioned by

the blow, his pulse becomes regular and good, his stomach easy, he is less agitated, his countenance revives, and he begins to feel pain, stiffness, and uneasiness in the part; he will *now* undergo the operation with the greatest advantage, and if he bear it well, of which there will be but little doubt, he will recover in the proportion of nine cases out of ten, in any operation of the upper extremity, or below the middle of the thigh, without any of the bad consequences usually mentioned by authors as following such amputations." "If, on the contrary, the operation be performed before the constitution have recovered itself, to a certain degree, from the alarm it has sustained, the additional injury will most probably be more than he can bear, and he will gradually sink under it and die."

"At the storming of Ciudad Rodrigo I amputated a thigh in a convent close to the breach, within an hour after the accident, at the anxious desire of the patient, the leg having been destroyed by the explosion of a shell. There was not more than the usual loss of blood, or of delay in the performance of it; my patient did not however recover the shock of the operation, and at daylight I found him dead, without the bandage being stained with blood."—page 25.

"When the thigh is destroyed by cannon shot, above or at its middle, the injury is very great, and the danger proportionate. The shock is frequently more than the constitution can bear, and the patient dies in a few minutes without much hæmorrhage. The loss of blood is sometimes great; and whenever this has occurred, it very much destroys the chance of success of the operation. The influence, however, of the injury on the *nervous system* is most to be dreaded; and this is so great that many, indeed the greater part of these kind of injuries, are generally fatal, without coming under the observation of the surgeon. An operation under these circumstances would only hasten the dissolution of the patient."—p. 27.

"A cannon shot struck an officer in the middle of the upper half of the right thigh at the battle of Toulouse. He was carried into a house a short distance from the place of accident, and I saw him a few minutes afterwards; the soft parts were torn to the groin, the femur shattered to the trochanters, the femoral artery, vein, and anterior crural nerve, fairly divided. He had lost more blood than is usual after a limb being torn away, but not any great quantity, and the hæmorrhage had ceased. He was pale, ghastly, and little able to move; showed great anxiety of countenance; the pulse small and quick; the skin clammy; his face bedewed with a cold sweat; he could articulate, but with difficulty, and did not ap-

pear to suffer much pain. *Here any operation would have been instant death.* As the fire of the enemy was very smart around the house, I remained in it with him and some other wounded, with the hope of being able to rouse him sufficiently by cordials and stimulants to bear an operation. He at first swallowed a little wine, but the constitution could not recover itself, and in about two hours he was dead."—p. 28.

"When the surgeon is satisfied there is no chance of saving the limb by prudent delay, the operation is to be performed as soon after the receipt of the injury as the state of the patient will permit; the only point to be considered is, if the patient have so far recovered the shock of the injury, as to be able to bear the additional one of the operation."—p. 47.

Now let us see what Dr. Hennen says: "The propriety of amputation on the field being admitted, the question naturally suggests itself, What is the proper period? *instantly*, on the receipt of the wound, or *consecutively*? The practical reply is, *With as little delay as possible!* While hundreds are waiting for the decision of the surgeon, he will never be at a loss to select individuals who can safely and advantageously bear to be operated on, as quickly as himself and his assistants can offer their aid; but he will betray a miserable want of science indeed, if, in this crowd of sufferers, he indiscriminately amputate the weak, the terrified, the sinking, and the determined. While he is giving his aid to a few of the latter class, encouragement and a cordial will soon make a change in the state of the weakly or the terrified; and a longer period and more active measures will render even the sinking, proper objects for operation. If, however, he is disappointed in his hopes, surely the dictates of common sense will point out the necessity of *procrastination*, and will restrain the surgeon from performing what he knows must *ultimately* be done, at a period where it is manifestly counteracting the object he has in view, to do it *at once*. When, therefore, he finds a patient with a feebleness and concentration of the pulse, fainting, mortal agony, loss of reason, convulsions, hiccup, vomiting, irregular chills, with stiffening of the whole body, universal feeling of cold and numbness, with sense of weight, change of colour, and other symptoms of collapse, so well described by Le Coute: he administers wine, warmth, and volatiles; and when due reaction is established, he performs that humane operation, the utility and necessity of which are now confirmed beyond the possibility of doubt or the influence of civil."—p. 49.

Dr. Wetherill says, "Mr. Huskisson bled profusely for a length of time, and until his clothes and all about him were literally

drenched in blood; and although the great blood-vessels of the limb were entirely denuded and exposed, *I am informed* no means beyond placing a handkerchief round the leg, were taken to stop the flow of blood; surely the hæmorrhage might have been instantly arrested by securing those vessels; or if this could not have been done (a circumstance not very likely), I should have immediately decided, as the only alternative left, upon removing the extremity with the knife; this would have been following the directions and practice of the most eminent surgeons of the day, and if it had failed of success, the expediency and exigencies of the case justifying the measure, there could be no blame attached to any party."

I have to *inform* Dr. Wetherill that, in anticipation of the favourable moment at which Mr. Huskisson might probably have borne the operation of amputation, a ligature was applied round the femoral artery, and that this was done *immediately on our first examination into the nature of the accident*. He says, "If this could not have been done, he should have *immediately* decided, as the only alternative, upon removing the extremity with the knife." Indeed! This kind of decision does not surprise me, and well befits the character of the man who proclaims for his motto, "*Ubi medicina deficit, scalpellum refugium reliquum est,*" which means, that *when the surgeon cannot do your business, the butcher must*; and such, too, he says, would have been "following the directions and practice of the most eminent surgeons of the day."

The profession will perhaps cease to wonder at the adoption of the choice motto of Dr. Wetherill, when they see that the chief features of his character are intemperance and impetuosity; for, what can be thought of a man who observes, in reference to the difficulties he met with in the operation of excision of the cervix uteri,\* that if they occurred in the same degree in a subsequent case, he would relinquish it in the vagina, *cut through the abdomen, and extirpate the whole of the uterus from above the pubes, as in the high operation for the stone*; and thinks that the escape of his patient, after the tearing open of the peritoneum and the protrusion of the intestines, which took place in the case he has detailed, warrants him in supposing that a fear of mauling that membrane, some three inches or so, has been too pertinaciously adhered to, and is a mere bugbear of the profession? Such practice may consist very well with a member of a Salunagundi university, or a graduate from Goose Creek; but no *British*

\* See THE LANCET for 2nd of August, 1838, p. 567.

surgeon, with the recovery of his patient and the fear of a coroner before his eyes, would dare to resort to such a measure; and I would seriously recommend to Dr. Wetherill's patients, if he has any, to pause before they again commit themselves to the chances of his *scalpelling*.

As if, however, Dr. Wetherill, before he had finished his letter, had already suspected the legitimacy of the conclusion he had come to, in pronouncing for *instant* amputation in Mr. Huskisson's case, he exclaims, "Nothing is more easy than to get up whys and wherefores, and to call in question the theory and practice of any man;" and allows that, after all, it *might* be urged in defence of the mode of procedure by the medical men in attendance, *that they had the advantage of seeing the case*, and, consequently, it may reasonably be supposed "they were in a situation the best qualified to judge and act correctly."—I shall now take my leave of Dr. Wetherill, first premising that I think his letter a wanton, indecent, and impudent attack, calculated only to disturb the peace of mind and confidence of the friends and survivors of the lamented gentleman, now no more; and, by advising him, when next he favours the profession with his lucubrations, at least to supply himself with an accurate detail of the case he writes upon, and to represent fairly the conduct of the men he may feel an inclination to vilify and abuse. I have the honour to be, Sir,

Your most obedient humble servant,

WM. ROBERT WHATTON.

5, Portland Place, Manchester,  
October 12th, 1830.

## MEDICAL JURISPRUDENCE.

### PRACTICAL COMMENTARIES ON DR. CHRISTISON'S PROCESSES FOR DETECTING POISONS.

WE this day present our readers with the first of a series of papers, intended to supply practical information on a subject of which, it must be admitted, very many practitioners remain in comparative ignorance, namely, the method of applying unimpeachable processes to the detection of poisons, and various other substances, the chemical characters of which may fall within the reach of medico-legal investigation. Our observations in each instance shall be founded on the processes lately recommend-

ed by Dr. Christison, in his *Treatise on Poisons*, and will consist,—

First,—Of the methods he has directed.

Secondly,—Of such modifying remarks as each individual subject may require.

Thirdly,—Of adequate instructions in the mode of preparing the tests, or re-agents, with ample explanations of the fallacies which their imperfection might occasion.

Finally,—Wherever it may be necessary we shall advert to the construction and simplification of analytic apparatus, and notice the substitutes which may be employed under emergent circumstances, or in remote situations. This particular department we shall occasionally illustrate by engravings, and thus furnish, in a small and convenient compass, an ample body of information on this deeply interesting topic.

The character of Dr. Christison, as an analytic chemist, stands in such high and deserved repute, that with some persons, we are aware, we may incur the imputation of unwarrantable presumption, when we refuse to transfer his processes to our pages without note or comment, while others may be disposed to regard our strictures as entirely superfluous. The high reputation of Dr. Christison, however, is one of the principal reasons that induces us to examine minutely into the validity of his opinions; for we have lived too long not to have learned ere this, how easily reputations are occasionally acquired, and how implicitly mankind, in general, may be guided by "authority" in matters of which they themselves possess little practical knowledge. Scarcely have five years elapsed since Orfila was regarded as so infallible a chemist, that to question the propriety of any of his directions in medico-legal analysis, would have been deemed little short of a heresy worthy of the fagot, while at present it is admitted by all correct toxicologists, that in some serious points he has given his sanction to egregious and dangerous errors. We might readily adduce numerous parallel instances of this kind if it were necessary, but this is quite sufficient to vindicate the present inquiry from such an objection as the first, while as to the second, we shall trust to the sequel for our defence. We shall now proceed to business, and accompanying Dr. Christison in the order in which he proceeds, we shall commence with the consideration of the chemical relations of the mineral acids.

The sulphuric, nitric, and muriatic acids, usually demand investigation under three different conditions. In the first place, when after administration, whether in suicide, murder, or mistake, a portion of the pure and undiluted liquid remains for examination. Secondly, when having been taken into the body, they become the sub-

ject of analysis in a state of admixture with the contents of the stomach, or vomited matter. Thirdly, after aspersions on the body or apparel. Such are the modifications enumerated by Dr. Christison, and to those we may add a rare, but interesting form, which we have once witnessed, namely, where a corrosive acid has been wilfully injected into a door-lock to facilitate, as was supposed, the entrance of robbers into the house it secured. Of the common properties of these acids, Dr. Christison speaks in the following appropriate terms—page 116.

“The only common properties that require notice are, the power of reddening the vegetable blue colours, for showing which litmus paper is commonly used, and is most convenient; and their power of corroding all articles of dress, especially such as are made of hair, wool, and leather. This last property is specified, though a familiar one, because it always forms an important piece of evidence in criminal cases. In order to apply it with accuracy, it is necessary to remember, that if the article of dress is a coloured one, it is generally rendered red by the mineral acids; but that the vegetable acids will also redden most articles of dress, although they do not corrode them.”

To this paragraph we have but one additional remark to append. In many places litmus can, by no possibility, be obtained. Unsized paper, dyed in a decoction of red cabbage, will prove an available and efficient substitute. Dr. Christison next proceeds to give directions for the detection of the sulphuric acid in its pure and diluted form.

“When concentrated, it is oily-looking, colourless or brownish, without odour, and much heavier than water, and it rapidly corrodes animal substances. If from these properties, and its effects on litmus, its exact nature is not obvious, it is to be converted into the diluted acid, in doing which the experimentalist will remark, that the mixture becomes very hot, if the water is not added too abundantly. When diluted, it is to be tested with litmus and tasted. An acid having thus been proved to be present, a little nitric acid is to be added, and subsequently a solution of the nitrate of baryta. If a heavy white precipitate falls down, it can be nothing else than sulphate of baryta, because no acid but the sulphuric forms with the barytic state a white precipitate insoluble in the nitric acid. The phosphate and carbonate of baryta are both soluble in nitric acid. In applying this test, care must be taken to employ nitric acid entirely free from sulphuric, an admixture which the common nitric acid of the shops almost invariably contains.”

The author also suggests the further examination of this precipitate by the following ingenious and satisfactory experiment :

“Collect the precipitate on a filter, wash, dry, and remove it, then mix a little of it (not more than two grains) with a small proportion of dry charcoal powder, and subject the mixture for two or three minutes in a covered platinum spoon, or in a fold of platinum foil, to the flame of a spirit lamp, enlivened with the blow-pipe. A portion at least of the sulphate is thus converted into sulphuret of baryta.\* To prove this, put the powder, with a little water, in the bottom of a small glass tube, add a little hydro-chloric acid, and then hold within the tube a bit of white paper, moistened with the acetate or nitrate of lead—sulphuretted hydrogen gas is disengaged, which will darken the paper, and likewise often betray itself by its singular odour.”

In the consideration of these processes there are two circumstances which demand rather more particular detail than Dr. Christison has given; the first is, the adulteration of nitric acid with sulphuric acid; the second relates to the mode of obtaining the evidence of these properties from the smallest possible quantity of the barytic precipitate. With regard to the former, it is quite evident, that, should the nitric acid employed to test the solubility of this precipitate itself contain traces of the sulphuric, a quantity of sulphate of baryta should thus be formed and remain undissolved. The method of remedying this defect, though exceedingly simple, should still have been pointed out in the text; it consists in the addition of a *dilute* solution of nitrate of baryta to the nitric acid, and allowing any precipitate which may occur to subside, and then removing the supernatant fluid. As to the second, attention to the following experiment will show that Dr. Christison's directions are not in their manipulation adequate to the detection of the *smallest* possible quantity of the sulphuric acid. A phial, containing the acid, was inverted, and its contents allowed to escape; in this position it was suffered to remain for forty-eight hours, till it was apparently dry; on close inspection, however, an extremely minute quantity of moisture, not exceeding the 100th part of a drop, was seen in the angle between the bottom and sides of the phial; by touching this with the extremity of a small glass tube, drawn out to the fineness of a hair, the fluid immediately rose by capillary ascent, and was easily removed to a bit of thick glass; it was then touched with an equal quantity of nitrate of baryta, previously mixed with a sufficient quantity of nitric acid, when a white precipitate was immediately procured. On heating the glass, the sulphate of baryta remained in

\* This is evidently a typographical error in Dr. Christison's text; it should be “barium.”

the form of a white crust, certainly not more than the 50th part of a grain in weight, a quantity far too small for reduction to the state of sulphuret by the method Dr. Christison proposes. This was, however, accomplished by mixing the crust on the glass with an equal quantity of charcoal, and heating it for a minute or two in a fine blow-pipe flame. The black colour of the charcoal soon disappeared, and after the glass had cooled, a minute drop of the solution of the acetate of lead, strongly acidulated with acetic acid, was dropped on the surface of the precipitate, when a deep-black stain of the sulphuret of lead was immediately produced. It is to be observed here, that the acidulation should always be with the acetic acid, since the nitric dissolves the sulphuret of lead, and a white precipitate is produced by the muriatic, which entirely obscures the effect.

We shall next quote Dr. Christison's directions for the examination of the contents of the stomach, vomited matters, and suspected stains, and also his opinions concerning the several fallacies to which the processes are exposed:—

“In the case of the contents of the stomach, vomited matter, or stains, the process is nearly the same as that for detecting it in its undiluted state. The suspected matter is simply to be boiled for a few minutes, distilled water being added, if it is a fragment of cloth or other solid; and after filtration, the fluid is to be subjected to the succession of tests mentioned above. The nitric acid, in the pretent process, has a double use. Besides keeping the carbonate of baryta and all other barytic salts, except the sulphate, in solution, it greatly favours the separation of the sulphate, and whitens it.”

“But it may be said, that it is liable to fallacy when the acid is neutralised, for most organised bodies, and particularly the secretions of the stomach, naturally contain sulphates which will yield the required precipitate. This fallacy can be obviated in the instance of the contents of the stomach, or matters of vomiting, only by limiting the inference in favour of poisoning to the cases in which the precipitate formed with the nitrate of baryta is considerable. In the instance of stains on clothes, however, we have a surer corrective in a comparative analysis of a sound portion of the same clothes. Thus, in the case of Euphemia Macmillan, Dr. Turner and I procured, from a corroded piece of a hat, 4.3 grains of sulphate of baryta; and from a sound piece of the same size, a scanty precipitate, too small to be collected; from a stained piece of a coat, 0.9 of a grain of the sulphate; and from an unstained piece, close beside the other, a faint haze, but no precipitate.”

In the analysis of the impure animal fluid, there is a precaution to be observed respecting the use of the nitric acid which Dr. Christison has not noticed, namely, that it should be invariably added *before* the solution of baryta, and the fluid allowed to stand for some time, for the following reason: in several animal fluids nitric acid causes a white albuminous, or caseous precipitate, *insoluble in that fluid*, and which by an inexperienced analyst may readily be mistaken for the sulphate of baryta itself. If, therefore, the *previous* addition of nitric acid cause a coagulation, filtration should be employed before the nitrate of baryta be applied.

With respect to the fallacies Dr. Christison so correctly mentions, we believe we can point out two other sources of deception of considerable importance; the first rather fortuitous, the second more constant in its operation; we allude to the medicinal employment of sulphur, and the sulphates of soda, potash, and magnesia. That sulphur, strange as the fact may appear, is liable to be converted into sulphuric acid in its transit through the mysterious laboratory of the digestive and excretory organs, has been indubitably proved by the experiments of Wöhler and Schleibinger, as far as regards the urine, and in our own observations in a series of extended experiments on the contents of the alimentary canal. Again, it is a matter of notoriety, that in a majority of cases of sudden illness in town and country, a “dose of salts,” whether Glauber or Epsom, is administered before the arrival of the medical attendant. A case may, therefore, be readily supposed to occur, in which a person may die of a sudden and suspicious illness; during which salts had been freely given; the contents of the stomach are examined, litmus paper is reddened (we apprehend that the operator will not usually taste such a fluid to examine its acidity any further), and on the addition of the nitrate of baryta and nitric acid, the precipitate is formed in great abundance. Under such circumstances, according to Dr. Christison's directions, if they be implicitly followed, the examiner should swear to the detection of sulphuric acid. Of course we confine ourselves, with Dr. Christison, to the *chemical* evidence, and do not take the morbid appearances into consideration, for these are so striking, as in some degree to supersede the necessity of an analytic examination at all. In all cases, therefore, we believe it will be essential to the chemical proof of poisoning in this case, that no sulphur, nor sulphates, should have been administered for some time before death. We may here add, that Dr. Christison, in another place, relates a case in which the sulphate of magnesia had caused death, when given to a child in rather an unusual dose.

In the preceding experiments there is no necessity for any particular apparatus. For communicating heat, the spirit lamp alone should be used, and a substitute for this may be readily constructed by fitting a cork with a tin tube, about an inch long, loosely into the mouth of a wide-necked phial. The blow-pipe is employed by working jewellers and watchmakers, and therefore can be easily procured.

As the nitric acid has already been fully noticed in several papers by a correspondent, we shall, in the next Number, advert to the processes for detecting the muriatic and oxalic acids.

#### DISCOVERY OF THE EXPANSION OF THE HORSE'S FOOT.

*To the Editor of THE LANCET.*

SIR,—In addition to my former letter, No. 361, page 687-8, I send the subjoined to disprove the *claim-all* pretensions to the discovery of the expansion of the horse's foot, asserted in No. 366, page 899, and, as brevity is the order of the day, I proceed without further preface. It is there stated, "These authors (says the writer, alluding to Messrs Freeman and James Clark) have long been familiar to me; but the passages quoted, taken as they are, without the context, would probably lead to incorrect conclusions in other minds." In what other way, than by extracts, is it possible to fairly contest and convey the opinions of different writers to the public in a letter through a journal, let me ask? for I am at a loss even to conjecture; but I can positively assure your readers, that *all* the extracts which have been made are fully borne out by the context; and, as regards the writer's *long* familiarity with these authors, which he would have us fain believe, I must observe, that it is only a few months since, on my showing him Mr. Freeman's able and splendid work, that he expressed his very great surprise on seeing so much had been said on the subject prior to Mr. B. Clark's publication. He admitted the book was entirely new to him, and on my pointing out several particular passages, he acknowledged the great justness of their application, and the author's very correct views of the expansion of the horse's foot. Similar admissions have also been made by him in respect to certain parts of Mr. James Clark's writings; and I am further enabled to assert, that in a conversation with Mr. B. Clark (the writer before alluded to being also present) on the merits of Mr. Freeman's book, he admitted, if the work in ques-

tion was *genuine as to date*, that Mr. Freeman was fully acquainted with the principle of expansion of the horse's foot, and that he was wholly entitled to the merits of it; but it is necessary for me to remark, that he first used a great many plausible arguments, of which he is so able a master, in order, if possible, to convince me that the work in question had been predicated on the title page by the booksellers, and that it did not in reality appear until after his own; but on that point I was happily enabled also to meet him, by informing him, that I had seen Mr. Freeman's book long before his was published. I had previously heard Mr. B. Clark make similar assertions as to the date several times. I need not, I think, now say, "To whom is the merit due?"

The writer instances Jenner and Milton in support of his claim-all. Allow me, therefore, to observe of Dr. Jenner, that he was a man of unassuming manners, neither covetous of pelf or fame, ever ready to acknowledge whatever information he derived from others, above concealment, and he never descended to low, mean, and degrading tricks to feed avarice or revenge, for he possessed neither; nor did he vulgarly abuse his professional brethren who differed from him in opinion.

What Milton did when he was seven or eight years old I am not enabled to say, or whether he had before that age studied anatomy, or described the circulation of the blood poetically or physiologically, I cannot tell; it appears, however, that Harvey discovered the circulation in or about 1619; that Milton was born in 1608, and that he lived many years after Harvey, who died in 1657, so that I believe those points avail the writer nought. A great deal follows about inventions, steam-engines, &c., that does not in any way appear to me to apply to the case; but as I intend hereafter to show that some of Freeman's excellent statements have been wrongfully departed from; that some of Mr. B. Clark's assertions are not only erroneous but injurious; and that he does not appear to me to understand the real formation and action of the foot, or the application of Old Blundevill's, now his own darling shoe; I shall consequently pass over this for the present.

It is next asserted by the all-claiming writer, that "The passages which have been taken from the works of Messrs. Freeman and James Clark, contain *all* that can be advanced in their favour." I most positively assure your readers, that some of the weakest only, if possible, were purposely extracted (i. e. in my former letter). I have now added one more, and if the limits of your pages would admit I could as easily give twenty, but as Mr. Freeman's

book will shortly be republished with extensive notes, it will then be attainable by those who may wish to examine for themselves, and you will, I presume, no longer be *expected* to insert it in your journal for the sake of the context.

"When, according to the general method, a long shoe with a broad web is unfortunately put on, which is made thicker at the heels than at the toe, the consequence which commonly ensues is, that of hindering the expansion of the heel of the foot, which, in that case, soon over-contracts itself. This circumstance produces very great pain to the foot, by occasioning too great a compression of the cartilages, and of the blood-vessels by which they are surrounded."—*Observations on the Mechanism of the Horse's Foot.* By Strickland Freeman, Esq. 1796.

"That they saw the expansion of the heels," says the all-claiming writer, "as they term it, I frankly admit, but they saw without understanding it." Oh! oh! they did see that, then; and pray what other expansion is there to be seen in the horse's foot? This the claim-all writer has very cunningly omitted to inform your readers, modestly refraining from saying one single word about the bow and string; is *In hac signa vincas* blurred from the escutcheon; are the 12s. pastboard gewgaws gone to oblivion? "Why they did not understand it," we are modestly kept in the dark; I will, therefore, venture to conjecture they were supposed by the writer not to have possessed, like himself, a superior capacity.

"As to Freeman's losing sight of expansion altogether, and leaving it as an observation he had made, bearing no important consequences, and leading to no valuable result," is such a false assertion, that it could only have been made for wilful misrepresentation, or by a person ignorant of the real merits of the book; I will, therefore, add one more short extract from very near the end to support my assertion.

"When a horse, therefore, happens to set his foot on a large pebble, or on an uneven-pointed stone in a paved street, his heel, which for reasons before given, will receive no injury from that stone, when shod in such a manner as to be able to expand itself, will be less liable to slip upon it than if covered with a shoe with cramps to it, the points of which only contribute to make the bearing of the shoe more uneven, where from the hardness of a pebble, or of an irregular pavement, the shoe is not able to enter it. The heels of the fore-feet should, therefore, on this, as on many other accounts, be permitted to expand themselves, by having that sort of shoes on which produces the least impediment."—*Obser-*

*vations, &c.* By Strickland Freeman, Esq. 1796.

The writer again goes on to assert, that the expansion of the foot was not understood by these authors, and that they "nailed their shoes on both sides." Now, pray is not Mr. B. Clark's darling shoe nailed on both sides? What quibbles and shifts are there not to be found for the purpose of soiling paper!

The idea of the writer's quoting Mr. Coleman's book to serve his object, reminds me of the devil's quoting Scripture, which he has ever been said to do when it would answer his purpose. To enter fully into this, and the immediately preceding points, would fill a LANCET, and consequently, as not being of very great moment, must be passed by for the present.

"I admit (says the writer, and really one admission is something from such a quarter) that he (Freeman) saw the expansive action of the foot, but he neither demonstrated it so as to be intelligible to others, nor made any particular application of it, &c." He certainly did not take out a patent for the discovery, or make any foolish hit so as to deceive himself and others; on that score then there is much more credit due to him. But I positively assert, and stand pledged to prove, that he (at least as far as I have been able to discover), of all writers, has the most correctly described the expansive and true action of the horse's foot. While on the subject of patents, as the writer alludes to them, I must confess that I do not see the *eclat* in sneering at those gentlemen who have been disappointed on taking out patents for improvements in horse-shoes—I particularly allude to Mr. Rotch, Lieut.-Colonel Goldfinch, with others; and he appears to forget, that Mr. B. Clark is among the number.—*See a copy, dated March 25th, 1806, Repertory of Arts, &c., Vol. 51, August 1806.*

The writer next, with mighty grasp, lays claim to *all* for Mr. B. Clark, "with whom (he says) the idea of this discovery was perfectly original, that he arrived at a knowledge of it whilst making experiments to relieve contracted feet, and not by any chance or casualty."\* This really is such a grasp-all and sweeping sort of claim that it is not easy to grapple with it; we will, therefore, place the writer on a par with the celebrated critic Dennis, who was always wont to claim the merit of being the author of every-thing great: being on a time at the performance of a play, in which some part required the introduction and imitation of rolling peals of thunder, the effect being great and well executed, the critic vehemently exclaimed,

\* How does this accord with Mr. B. Clark's own account further on?

"That's my thunder! tis all my thunder!" The writer may, therefore, console himself with not being the first who has overshot the mark; but more of this anon.

To proceed, Mr. B. Clark did, however, publish some years ago an experiment which we will suppose he made, on one mare's foot for a succession of years, but that he need not have taken the trouble to do, if he had studied those authors who had preceded him; and after all it is only one instance, and as I am not aware of his having treated us with a new course in his republication, we may fairly presume he has none to give us, and, therefore, at best it is only solitary evidence, as M. Girard very justly observes.

If my memory does not fail me, Mr. B. Clark has somewhere modestly said of himself that his labours have been "blessed with many discoveries of no mean importance" (in his own opinion of course). What a blessing then it would be for us to have them in a narrow compass, as we might then fairly examine them, and contrast them with the opinions of others, who, unfortunately for Mr. B. Clark's credit and investigation, have too frequently a prior claim to them, although they may have been possibly discoveries to him! I copy, for example, the following, which will in some measure show with how little ceremony he has treated preceding writers, though the claim-writer of the letter would perhaps have us believe, and apparently wishes us to do so, that Mr. B. Clark was wholly unacquainted with all who wrote before him, and thus to account for his perfect originality.

In alluding to the old writers' ignorance in one of his numerous publications, Mr. B. Clark says Osmer was an exception; consequently we presume he ought to have been well acquainted with his book, wherein I find the following set down, and as I did not advance it as proof in my last, I shall do so now, and if Mr. B. Clark did not understand that writer's very plain language, I can only attribute it to the dullness of his perception and comprehension. "On the other hand (speaking of the indiscriminate custom of stopping and greasing all sorts of feet), the hoof being capable of contraction and expansion, strong feet cannot be kept too full of oil, for the reasons before given."—*Treatise on the Diseases and Lameness of Horses.* By W. Osmer, 1761, page 53.

Mr. B. Clark has likewise stated that "James Clark of Edinburgh is also an exception, having a good deal of good plain sense and sound observation in his writings; and he was supposed by many intelligent persons to have exhausted the subject of shoeing and the foot, yet was he wholly unacquainted with the infected nature of the horse's hoof or its bulbs or frog-band,

on the functions and structure of the frog; nor had he any consistent notions as to the real cause of the contraction of the foot, or any idea of the changed state of the coffin-bone in this disease." Now reader, pray contrast this with what Mr. James Clark says, page 5, and consider how far we are justified in placing confidence in Mr. B. Clark's writings without due examination. "The crust (and by some the wall) is of a tough hard substance, thick and strong at the fore-part or toe, but thinner and weaker towards the heels, it reflects inwards and forwards to the point of the frog, there it is termed the bars or binders of the foot." His opinion of the frog, which is equally correct, was quoted in my last communication, and need not be repeated here. On contraction of the foot at page 16 he states, "The heels, as has been observed, being forced together, the crust presses upon the processes of the coffin, and extremities of the nut-bones; the frog is confined, and raised so far from the ground, that it cannot have that support upon it, which it ought to have; the circulation of the blood is impeded, and a wasting of the frog, and frequently of the whole foot ensues."

I have next to revert to Mr. B. Clark's own account of, and manner of becoming acquainted with, the bars or infections of the hoof. "The actual construction also of the horse's hoof was laid open to me in the following manner:—A young fresh hoof had lain on my desk some days, and tired almost of seeing it, I determined, without any particular object, to make an horizontal section of it, and throw it away; in inspecting it, after sawing it asunder, I observed the loose edges of the frog-band and bulbs, and tracing them found them to make one entire unbroken circle round the hoof, to my great surprise, as the hoof's structure then admitted of an easy explanation; the bars were next seen to be portions only of the wall infected inwards towards the centre of the foot, so that the hoof consisted simply of two circles, one of elastic horn, and one of firm horn instead of several parts, as was before imagined; the sole being merely a supplementary part uniting and filling up these parts, and closing the lower opening of the hoof."

Notwithstanding the chance which let Mr. B. Clark into the knowledge of this description, every point of it which is correct was well known, and had been described years before, by Osmer, James Clark, &c. As I have already trespassed to a considerable length on your columns, I shall be compelled to defer what I have to advance on the structure of the foot, to a more favourable opportunity.

And remain, Sir,  
yours, much obliged, &c.,  
B. HART.

September 7, 1830.

## DISSENSIONS IN THE UNIVERSITY OF LONDON.

To the Editor of THE LANCET.

SIR;—In consequence of two professors, supposed, on account of their conduct, to have been Professors Davis and Conolly, having gone to the warden and alarmed him by stating, what is known by all my friends to be untrue, that I intended to excite a disturbance at the Medical Society of the University,—the warden, without saying any thing to me, or to any of my friends, ordered the porter to prevent my entrance into the University. The pupils, therefore, like honest men, gave me that hearing, which the council and warden had denied me, and afterwards sent me the following documents, of which I am indeed proud, because they show the rising spirit of the young men of the present day. You will oblige me by publishing them with my answer.

ALEX. THOMSON.

“ University of London, Oct. 14.

“ Dear Sir,—We have great pleasure in enclosing the resolutions agreed upon at the meeting yesterday, with only two dissentient voices, and remain,

“ Dear Sir, yours very truly,

“ N. EISDELL, Chairman.

“ T. HOWITT, Secretary.

“ At a meeting of the medical students of the London University, held in their common room, on Wednesday, the 13th of October, 1830, it was resolved, that

“ 1. This meeting views with anxious concern the unmerited displeasure of the council, lately manifested toward their fellow student Dr. Alexander Thomson.

“ 2. Dr. A. Thomson having fully laid before the students of the University, every particular of his late conduct in connexion with that institution, and submitted to their perusal authentic documents in support of his statements, this meeting begs respectfully to intimate to the council its unqualified approbation of the motives Dr. Thomson acted upon in the transactions alluded to.

“ 3. The students are fully aware of the deference they owe to the ordinances of the council, but cannot view, without apprehension, the summary measure which has been put in force in the case of Dr. A. Thomson, viz., his extraordinary expulsion from the University. They conceive it to be a public institution, established on a system of enlarged and scientific usefulness to society; and, they think themselves called upon to enter their firm protest against the dismissal of a pupil from its class-rooms, without his having violated any known law, any hearing of evidence, or even an official notice of his

dismissal. They are convinced that a proceeding so arbitrary, irregular, and unjust, is incompatible with the best interests of the University, and subversive of the liberal principles, to which it owes its foundation and support.

“ The following students have appended their names to the above resolutions:—

65, N. Eisdell, Chairman.

| 48. T. Davie           |                           |

Many of my fellow pupils have called upon me, and informed me, that double the number of names would have been appended, had a communication not been made from the office, stating that I was not a matriculated pupil. As soon as I heard of this, I sent the following letter to the warden:—

" Sir,—Having received a very gratifying communication from ninety-six of my fellow students, approving of my conduct in regard to Professor Pattison, and having been informed by many others of them, who have not appended their signatures to this document, that they have been restrained, by a communication from the office affirming that I am not a matriculated student, from appending their names to this document, the whole tenour of which they otherwise approve; I beg to express to you my surprise at such information, and to inform you, that the moment I heard of it, I went to the office and tendered my money for a library ticket, which was refused. I assure you, that I have been attending the University under the belief that I was a regularly matriculated student; for, when I feed Dr. Davis for his lectures, he informed me publicly, in the presence of his class, that his share of the money at least would be remitted to me from the office.\* This money I have never received, although I have more than once applied to Dr. Davis for it. I concluded, therefore, that this money was left for me at the office, where I wished it to remain, as my matriculation fee. Under this belief I attended many of the lectures last year. Again, Sir, I wish to ask of you whether, as a gentleman permitted by the council, through courtesy, to attend lectures in their institution, they give you authority to prohibit my entrance without sending me any written document, and through the mouth of the porter? Again, Sir, I wish to know whether you can expel me from, or prevent me entering, the medical society, of which I was the founder, as well as framer of its laws, and am still an honorary member, having paid all my fees. If I, an old pupil by your acknowledgment, am excluded in this manner, of what use is it to me to have paid all my fees to that society? An answer to these queries will oblige

" Your obedient servant,  
(Signed) "ALEX. THOMSON.

" October 15th, 1830."

*To those Pupils of the University of London, who have signed the Protest to the Council in favour of Dr. Alex. Thomson.*

" Gentlemen,—Allow me to return you my thanks for the kind interest you have taken in my welfare; I wish you had rather had moral courage enough to have insisted

\* There is an agreement among the professors, that they will receive no money from their colleagues' sons. But the council do not sanction this agreement, and, therefore, the sons are obliged to purchase a library ticket each year, as no one is permitted to buy a library ticket who does not intend to enter to a course of lectures, to pay that part of the fee which goes to the University chest.

upon your own rights; and then you would not have been insulted by the council,\* who after reading your testimonial, sent me a letter, of which the following is a copy :—

*Copy of the Warden's letter to Dr. Thomson.*

" University of London, Oct. 15, 1830,

" Sir,—I have laid your letter of this date before the council, and I am directed to transmit to you the following resolutions of the council passed this day :—

" " That Dr. Alexander Thomson be not permitted in future to come within the precincts of the University, and that the warden do give the necessary orders for carrying this resolution into effect.

" " That a copy of the preceding resolution be transmitted to Dr. Alexander Thomson."

" I am, Sir,

" Your very obedient servant,

" LEONARD HORNER, Warden.

" Dr. Alex. Thomson."

" Moreover, Gentlemen, they have come to a resolution to take no notice whatever of your protest, and on no account to acknowledge the students as a *body* possessing any rights, but such as they in courtesy may choose to grant. If you are idiots and cowards enough to submit to this, you deserve all the inflictions which that body can impose upon you, and will, in the language of your haughty professor of midwifery, be "*crushed*." I have done my duty in giving you the opportunity of asserting your independence: I deeply regret the existence in so large a body of young and strong men, of the pusillanimity and weakness of intellect which has made you neglect it.

" Your fellow student,

" ALEX. THOMSON.

" October 18th, 1830."

MEDICAL ELECTIONS.

*To the Editor of THE LANCET.*

SIR,—I and many of my brother pupils should esteem it a particular favour, if you would insert in your LANCET of next Saturday, the following passage from Mr. Dermott's introductory lecture. You will, I am sure, be pleased to learn, that the entire address consisted of an able condensation of those arguments which you have so repeat-

\* It is better, however, to observe to you, that not more than six members of council met on this occasion, as I am credibly informed by two of the professors, Dr. Birkbeck and Mr. Starch were, I am also told, of the number.

edly used in THE LANCET in favour of a RADICAL MEDICAL REFORM.

I am, Sir, your obedient servant,

A PUPIL.

"Now it is the aristocracy both in medicine and politics (and by the term medical aristocracy I mean monopoly of power) which is the *proximate cause* of the tyranny of private interest and intrigue—that tyranny which always tends to crush merit, whether it be in medicine or in politics—and that tyranny which has been the disgrace and partial ruin of the English. Where, I may observe, we have an overpowering political aristocracy, we shall, as so many contaminated ramifications of the root, find the same system of things existing in, and regulating the departments of, science, and in every thing else connected in an important way with the nation—first begotten by the aristocracy, and then aiding in the support of its fruits or measures. See how members are elected to rotten boroughs, professors to government institutions, and hospital surgeons to hospitals: it is all one piece of contamination; instead of the election of medical officers being upon the basis of merit—instead of men being publicly elected by all the members of the profession, they are shuffled in by the intrigue and private interest of themselves and their friends, who are non-medical and quite incompetent to judge of medical matters and the merits of medical persons. This, then, is the scourge of England—that public good is sacrificed to personal influence and interest. And why? Because there are no laws and regulations to counteract it. Medical politics always were linked with, or immediately affected by, general politics, and cannot be completely separated from them; it is on these grounds I say (and I am encouraged to speak in this strain from the impulse of the moment, because I see many members of the medical profession now present), that every medical man should be a politician.

"Let us turn our attention to France: there the medical profession is immediately under the wing of a liberal government, and there we find a purity existing in its economy, and merit justly regarded as the only means of recommendation to public favour. Now, then; that our brethren, the French, are opening the sluggish eyes of Englishmen from their lethargy, and now that we have a virtuous king upon the throne, who is in *reality* the king of the English, if not, unfortunately, *nominally*, let us hope for the days of merit to shine upon England, 'that every growing merit shall succeed to its just right,' and make the grove harmonious.' But we must recollect that hope alone will not do this; the members of the

medical profession must effect it; and while they allow the evils to remain, and do not *act* to remove them, they must blame themselves."

#### REFLECTIONS ON THE LATE INQUEST AT HAMPTON.

To the Editor of THE LANCET.

SIR,—It is impossible to review the proceedings at the late inquest at Hampton, which called for your animadversions in the last Number of your impartial Journal, without a full conviction of the gross ignorance of the practitioner whose conduct was the subject of investigation, or without a due share of surprise at the verdict delivered, together with the utmost sympathy for the unfortunate sufferer. The proceedings on the part of the surgical attendant were such as no one would have anticipated in the earliest period of the practice of midwifery, and yet attempts were made to palliate the blunder, and even a grave professor of midwifery, to whose skill, probably, the accoucheur was indebted, had the effrontery to sanction every stage of the proceeding, and to justify the removal of the superior extremities in a presentation of the face of the child. It is perfectly unnecessary to go into a full detail of this case, as you have already supplied your readers with a full statement of it; but from the evidence of the female accoucheur, whose testimony was delivered in a plain and simple manner, it appeared that the head was in *some* degree advanced below the upper strait of the pelvis, when Mr. B——n was called in, and that no part of the arm had protruded. Opposed to this, we have the opinion of Mr. Jewel, who was not present at the time of the labour, that it could *hardly* be called a *face* presentation, but that the arm *must* have fallen down." Most practitioners, who are conversant with the difficulties of preternatural presentations can certify, that the face of the fœtus with one hand will not unfrequently be found to present simultaneously; such might have been the phenomena on this occasion. The obvious indication would then have been to have returned the hand, and to have made some pressure on the face, with a view to bring the occiput nearer the symphysis pubis. Where we cannot accomplish this turn by assiduous and *gentle* means in a *reasonable* time, provided the woman's strength is not exhausted, we have been advised by Denman to wait for nature's spontaneous effects; or, to use the language of Mr. Taylor, to allow the head to *right* itself. If the surgeon in attendance was not equal to this mode of administering relief, before he had

determined on so barbarous and ineffectual an expedient as that of tearing the child limb from limb, it was incumbent on him to have suspended any further forcible proceeding, till he could have availed himself of further advice. It appeared in evidence, that Mr. Taylor had succeeded in delivering the same patient on a prior occasion by turning. What could have been more rational on the part of the friends, than to solicit his aid. The woman's conceiving that the child was dead, would not authorize any accoucheur in the premature dismemberment of the child. But we are told that the practitioner had exhausted *all* his skill, and found the *common* instruments unavailable; that it was therefore allowable to indulge him with a boot-hook, previous to which he had dislocated the cervical vertebrae, and inflicted some injury on the head; indeed, as the coroner had *learnedly* expressed it, "he had not made a *half* business of it, but persisted to the last," and resolved that one arm should not survive the delivery of the other. Taking it for granted, that the head was not impacted in the pelvis, which, we are informed, was very capacious (though the child is stated to have exceeded the common bulk of a full-grown fœtus), the same room that allowed of the introduction of the surgeon's hand to tear away the arm, might have been afforded to ascertain the situation of the feet, which in this instance must have been close in contact with the fundus of the uterus. I am far from wishing to underrate the difficulties of turning a fœtus where the membranes have been long ruptured, and can truly attest, that having once secured a foot, I have felt a sort of Pythagorean ecstasy in the prospect of a speedy termination of delivery. In the unfortunate example under discussion, it would be quite as revolting to sound practice to have proposed craniotomy, as that of the violent separation of the superior extremities. Upon surgical assistance being called in, the only legitimate mode of rescuing the patient from her future suffering, was that of a steady but fixed determination to deliver by the feet. What advantage towards the full exclusion of the fœtus can attach to a removal of the upper extremities as a precursory measure? The answer given by Mr. Jewel, that "when one arm was taken off, there is more room to take off the other," will hardly satisfy any tyro in midwifery, although he is obliged to admit, that it *could* have been turned *only* with difficulty. But this difficulty *ought* to have been surmounted. "*Humanum est errare*," but who would not have sacrificed any petty feeling of jealousy, on the score of other advice, by consenting to call in aid, in seasonable time, when the life of a fellow-creature was at stake, and both parties perhaps have shaken

hands on the issue of the case, rather than to have insulted the wounded feelings of the family, by persisting that the patient would soon be released by delivery, when the least reflection might have taught him, that the practice employed could not in the least justify so favourable a prognostic? The verdict delivered in this case was a plain sacrifice of truth and honesty, to an unaccountable degree of false delicacy. In every science a set of rules or axioms is necessarily established for the general guidance of those who are called upon to act; and no one can be justified in discarding those rules after they had obtained the universal sanction of the most enlightened practitioners, in order to embark on a hopeless emergency without an anchor, or a particle of prudence to direct the accoucheur. The fatal consequences of such a violation of reason must be too obvious to need any further comment; or, at least, the salvo of another practitioner *ought to be considered as the indispensable law of the land*. That a mistake like the foregoing will never be again recorded in your useful Journal, is the sincere hope of,

Your obedient servant,

OBSTETRICUS.

#### POPLITEAL ANEURISM.

To the Editor of THE LANCET.

SIR,—In your Number of THE LANCET for September 18th, 1830, you have published the remarks of Mr. Lawrence on a "Case of Popliteal Aneurism," in which, in my opinion, he relies too much on the *bruit de soufflet*, as indicating circulation of blood in the aneurismal tumour. From experience we know that there are aneurismal tumours in which there are evident signs of circulation of blood, such as pulsation and reduction of the tumour by pressure, without the *bruit de soufflet*; and again, there are tumours that press upon arteries in which we have the *bruit de soufflet*; hence we have circulation in an aneurismal tumour without the symptom, and we have a tumour in which there is no circulation with it. I remember seeing the common carotid taken up for a tumour in the neck, from this very symptom, in which death from hæmorrhage took place in three weeks after the operation, and dissection proved the case to be one of fungoid tumour pressing upon the artery; this first made me think of the cause by which the symptom must be produced.

The cause of *bruit de soufflet* appears to me to be the rush of blood through a contracted space. This may be in the artery, or, as I think very seldom, takes place in the

neck of the aneurismal sac. The artery may be contracted from pressure, as from an aneurismal tumour, which the surrounding parts bind down upon the artery, or from any tumour in the seat of an artery under the same circumstances, and pressure on an artery with the finger will cause the *bruit de soufflet*. That the *bruit de soufflet* seldom, or indeed never, takes place in the passage of the blood into the aneurismal sac, may be accounted for in this way: the blood at that part, instead of having a contracted space to pass through, has a much more capacious one, having the artery and the opening of the aneurism, the latter of which alone, except in very early cases, exceeds generally the circumference of the artery. So that, in my opinion, *bruit de soufflet* is seldom indeed caused by the passage of blood through the neck of the aneurism, but by pressure upon the artery contracting its size; and the reason that some aneurisms have this symptom, whilst others have not, is, that some aneurisms, whilst the blood is in a fluid state, form little or not sufficient pressure to cause it, although, when in a farther state of progress, the symptom comes on from their increased size and more firm texture, from the coagula which they contain.

Yours, Sir, respectfully,

J. B. E. FLETCHER, Surg.

Shifnall, Shropshire, Sept. 29, 1830.

## ARMY ASSISTANT-SURGEONS.

SIR JAMES M'GRIGOR.

### To the Editor of THE LANCET.

SIR,—In your last Number I observe with pleasure a letter from “A Poor Assistant Surgeon,” in which the writer gives something like the real character of Sir James M'Grigor (not that one which he might be supposed to possess from reading the fulsome “dedications” of expecting sycophants) in confirmation of his opinion of the worthy knight. Allow me to make a few remarks on the promotion in Sir James's department. I shall select as my text the following sentence from the last Gazette:—“Assistant-Surgeon H. J. Jemmett, from the 12th Light Dragoons, to be surgeon to the forces.” On looking to the army list, Mr. Jemmett's commission as assistant-surgeon is found to bear date “13th of Dec. 1825.” Now as the regulations state that “every gentleman must have served at least five years in the junior departments before he can be promoted to the rank of regimental surgeon, it appears that, as soon as possible, Mr. Jemmett was appointed sur-

geon to the forces, a rank which, by the custom of the service, is superior to that of regimental surgeon; and speaking of which, the regulations say, “Medical officers are encouraged to look forward to the rank of surgeon to the forces.” Contrast this promotion with that of the late senior assistant-surgeon to the forces,\* who, in the same Gazette, was appointed to a regimental surgeoncy after *nineteen years'* service as assistant-surgeon!

Look to those gentlemen still remaining on the list after sixteen, seventeen, eighteen years' service at home and abroad. In tropical climates no surgeoncy to the forces comes in their way, but Sir James promotes over their head an assistant-surgeon of five years' service at home; and while they are toiling in St. Lucie, Ceylon, Dominique, &c., stations him at Edinburgh! Even look at the services of the assistant-surgeons of the other cavalry regiments; look at Mr. Ribbeck of the 10th Hussars, who, among other testimonies of his services having been performed elsewhere than in the different cavalry stations of Canterbury, Edinburgh, Dublin, &c., bears a Waterloo medal. He is still an assistant-surgeon, and with a commission dated 2d of July, 1812!! That it may not be said this is a solitary instance, we may mention Mr. Barry, Royal Dragoons, Feb. 1813; Mr. Stewart, Scots Greys, Nov. 1813; Mr. Cross, 3d Dragoons, March 11th, 1813; in short, among our dragoon regiments alone, there are six assistant-surgeons of seventeen years, and three of sixteen years' standing, not to mention later dates.

The conclusions from these premises are evident, and I think an instance of more flagrant and shameless partiality is rarely to be met with. I am sure, unless Sir James be lost to all sense of shame, he must have blushed in recommending (as the phrase is) the appointment. Is it not melancholy to think, that eighteen or nineteen years' hard service at home and abroad is not considered as entitling a man to promotion, or to a better station than Jamaica, or St. Lucia? Or that an application for promotion on these grounds is to be answered (as I have known it done) by an offer of an appointment to Sierra Leone! Mr. H. J. Jemmett's private and professional character stands (and I believe deservedly so) high, but these are not the claims Sir James looks to. Mr. Jemmett is so fortunate as to have a father in an official situation (we believe in his Majesty's household), and thence his rapid advancement is easily explained.

From your always having been a decided enemy to all kinds of “hole-and-corner” work, I am induced to hope you will afford

\* Dr. Hart.

me a nook for this in your next, with the laudable view of *proving* to those expecting to enter the service, that as long as the present chief remains, \* \* \* not public service, ensures promotion.

I have the honour to be, Sir,

SCALWELLUM.

Dublin, Oct. 7, 1830.

### NON-MEDICAL CORONERS.

[We have lately received a vast number of letters relating to non-medical coroners, and as we find space shall select some of them for insertion. The following are of the number.]

#### *To the Editor of THE LANCET.*

SIR,—In the summer of 1795, while the 4th Buffs and another regiment were encamped on Hopton Common, a place half way between Yarmouth and Lowestoft, a few straggling soldiers called at Hopton White Hart, and spent an hour or two in festivity. One of them accidentally broke a quart mug, for which he refused to pay. The landlord, Robert Wightman, locked up a firelock as security; a scuffle ensued, in the course of which John Wightman, the brother of the publican, snatched up a poker from the fire, and struck one of the soldiers, from the effects of which blow he died. An inquest was held by the coroner of Suffolk on the dead body, assisted by a magistrate, the Rev. Dr. Cooper of Yarmouth, the father of Sir Astley Cooper, and the grandfather of the gentleman who lately cut so distinguished a figure in the pages of *THE LANCET*. The coroner charged that the offence was clearly murder; the jury thought otherwise, and brought in a verdict of manslaughter against John Wightman, and acquitted Robert Wightman. The coroner refused to receive the verdict, and, in conjunction with the Rev. Magistrate, lectured them severely on their contumacy, in daring to bring in a verdict contrary to the opinion of "the court." The jury, inexperienced, and overawed by authority,—moreover assured that a verdict of murder against John would not at all affect Robert Wightman, their harmless, inoffensive townsman, whom they were desirous of saving from the consequences of his brother's violence,—finally brought a verdict of "wilful murder" against John, and acquitted Robert, Wightman.

Now, Sir, mark the consequence. On the succeeding day the Rev. Dr. Cooper, acting on his authority as a magistrate, committed Robert Wightman to Bury jail to take his trial for murder as "an accessory

before the fact." At the trial the grand jury found a true bill against John, but ignored the bill against Robert; their foreman, Mr. Maynard, afterwards Sir Arthur Heselrigg, indignantly asked the judge in open court, if an action would not lie against the committing magistrate for false imprisonment, which he answered in the affirmative, but coupled with an opinion which rendered the whole matter nugatory—I suppose, the necessity to prove a corrupt motive. John Wightman was found guilty of manslaughter. Thus, through the want of firmness and independence in the coroner, did this innocent man suffer thirty-three weeks of unjust imprisonment, which caused the total ruin of his health and fortune. His widow and children, six of whom were girls, must have become the inmates of the poor house, had not the oppression of their father, and their own universal good character, excited the sympathy of a few of their more wealthy townsmen, who gave them the means of establishing a small business, which has to this hour supported them in comfort and respectability. I am, Sir,

Your most obedient servant,

J. T. MURRAY.

SIR,—On referring to a late Bristol journal, you will find the report of a coroner's inquest held in this city, on the body of Mary Lewis, ætat. 23, who was found suspended to the banister of a stair, and although cut down in about three minutes, death took place within two hours after, and a verdict was returned of *felo-de-se*. An examination of the body was strongly urged by the foreman of the jury, as well as by the two medical men who had administered to her in her last moments. This apparently reasonable request was obstinately refused by the coroner, who stated it to be unnecessary and absurd, although the lower part of her shirt was completely saturated and clotted with blood, which, being dry, rendered it quite stiff. The os tincæ was very near the external orifice of the vagina, and was soft and so dilated that the finger passed with the greatest ease into the uterus; on withdrawing the finger no blood appeared upon it. There was no swelling of the external parts.

I have confined myself to a mere detail of those appearances which in my own opinion would have justified a more extensive examination of the circumstances connected with her death, and shall concede to you the power to make any comments you may think consistent with the advancement of the cause you have of late so ably advocated.

A. B.

A correspondent, Colonel Blennerhasset Fairman, in drawing our attention more espe-

cially to the case of coroners' inquests in jails, observes,—

When deaths happen in a prison, the jailors, from a fear perhaps that the frequency of such occurrences may, in the end, endanger the duration of their own establishments, by awakening the sensibilities of the nation, do every thing in their power to keep these calamities from the knowledge of the public. The juries are too often packed from their own tradesmen—the inquisition is precipitated, and hurried over with indecency—no announcement of the proceedings is ever made to the survivors in custody, while indeed obstructions are thrown in the way of those who may wish to attend the court, and be present at an examination in which all are interested. In fact the business is despatched as a mere matter of form, with all possible speed, in the most slovenly way, as if an indemnity to the jailor and a fee to the coroner were the sole purposes for which the jury had been assembled, and not the circumstances that had produced, had contributed to, or accelerated, the dissolution of the defunct; of whose safety the legislature was so jealous as to institute these inquisitions, lest men thus cut off from their family and friends might occasionally be sacrificed, as heretofore has been the case, to the vindictiveness, the oppression, and inhumanity of their keepers. ‘Died by the visitation of God’ is the return nine times out of ten, when the verdict ought to be of ‘a broken heart, through persecution the most relentless or unjust,’—‘of disease brought on by a removal from a bed of sickness to a place of incarceration,’—‘of abstinence and starvation through the absolute want of the comforts and necessities of life,’—or, perhaps, ‘from excess of drinking, brought on by anxiety and dejection of mind, through a long confinement.’ Lawyers are connected, more or less, with the governors of prisons, for whom they entertain a sympathetic sort of feeling; they are subservient, too, more or less, to the judges, and stand identified, in some measure, with the courts. For this sole reason, if for no other, they are not the fittest, the most unprejudiced folks that might be selected for the execution of a trust so precious, and for the discharge of a duty so paramount, as that of deciding on the circumstances which may have occasioned, have conducted to, or hastened the dissolution of victims to a system the most barbarous that ever shed disgrace on a civilized state, not to say a boasted land of liberty, in an enlightened age of freedom and refinement.

## ERRATUM.

To the Editor of THE LANCET.

SIR,—In page 103 of the last published Number of THE LANCET, you will perceive so palpable an omission on the part of your printer, that I am sure you will be as eager to supply it as I can be. Between the fifth and sixth lines of the second column, a passage has been struck out, which not only formed part of my *lecture*, as it was delivered, but which I perused in the proof you had the goodness to send me. I do not request the restoration of the entire passage, but (as several persons have very naturally observed) what immediately precedes the *hiatus* is unintelligible, as the whole actually presents itself. If, however, the portion of my MS. has been suppressed by *design*, I beg to say, that although I am willing to submit to a law which I uniformly enforced when myself an editor, the law, viz., of acquiescence in editorial discretion and responsibility,—I do submit, with all deference, that when a person sufficiently known to the public appends his name and quality to a contribution, the editor is expected, if he admits the paper, not to dress it, as the author releases him entirely from all liability concerning it. If I am in error, I shall be glad to be corrected; but I think that the whole of this affair is a typographic oversight.

Be good enough to let this communication appear in your next Number, and to give me the opportunity of informing your readers, that the *essential* passage omitted was to the following effect:—

“As long as the Jewish nation lasts, I, for one, *must* believe the Bible.”

I am, Sir, your obedient servant,

J. GORDON SMITH.

Euston Square, Oct. 18, 1830.

CURE OF CORNS BY LUNAR CAUSTIC.—I applied it (the lunar caustic) thus. I put the feet in warm water, and allowed them to remain till I found the outer surface of the corn was soft; I then dried the feet and applied the caustic all over the corn; in a few minutes it was dry; it remained so for ten days, when I removed the black skin and applied the caustic again; and so I continued till I had completely eradicated the corns. I have tried the same plan with many of my patients, and those who have been sufferers for years, all have been cured; it produces no pain, nor the least inconvenience, and does away with the necessity of cutting, which is dangerous in itself, and likely to produce extensive inflammation, with, frequently, the loss of life.

C. V.

Rotherhithe.

## THE LANCET.

*London, Saturday, October 23, 1830.*

IN the multifarious forms of royal charters and of legislative enactments, there is not to be found, upon any one subject of legal inquiry, a more heterogeneous mass of legislative and royal absurdity, than in the laws which have been framed for the government of the medical profession. The immortal MILTON has observed, that

“ So many laws argue so many sins.”

But, had he lived in the present day, he might with more propriety have stated, that they argue, rather, the folly and stupidity of those by whom they have been enacted, and the avaricious knavery of the corrupt creatures by whom they were projected. Of all the acts of Parliament, of all the Charters, is there one upon which any man can place his finger, and say truly, “ Here is a comprehensive law, suited to the dignity, character, and welfare of the members of the medical profession, and calculated to promote the best interests of the public.” From the reign of HENRY the EIGHTH to that of GEORGE the FOURTH, there is neither a charter nor an act of Parliament upon the subject of medical polity, which, in the restrictive character of its clauses, would not disgrace the lowest mechanics’ club. The interests of the *few*, in these measures, have invariably been consulted, while the interests of the many have been, as uniformly, wholly disregarded. This may appear paradoxical, but it is nevertheless true; indeed the reasons are obvious, and may be stated in a very few words,—The *many* have been *idle*, the *few* have been *active*. Consequently each “ act,” each “ charter,” has echoed the voice of a faction, and not that of the multitude. The petitioners for charters and bills have never forgotten their own interests, and while bawling most loudly, while stunning the ears of kings and

No. 373.

members of Parliament, for instruments of public protection, they have been most actively engaged in forming plans for their own private personal aggrandizement. The establishment of an *aristocracy* in medicine, in the reign of HENRY the EIGHTH, has proved a great check to the cultivation of medical science in this country.

The COLLEGE of PHYSICIANS has been an *upas* to the profession. It has proved darkness to the light of knowledge; a blast to every thing that has been deemed liberal. How could it be otherwise? What purity, what liberality, could flow from the corrupt and vicious heart of such a vile sensualist as HENRY the EIGHTH? And yet, even to the present hour, the College of Physicians claims no other support, has no other pretext for maintaining its unprincipled and pernicious monopoly, than the charter granted by HENRY to his favourite physician LINACRE. Founded at the request and under the sole dictation of this one physician, it is not extraordinary that the welfare of the profession for succeeding generations should have yielded to the private interests of that individual and his self-elected successors; but it is extraordinary, nay, it is scandalous, that, in the present advanced state of society, the building is not daily shaken to its centre by the indignant voice of the profession. Here, then, is the first key towards explaining the problem forced upon the attention, by contemplating the narrow-minded and miserable enactments for medical government. The College of Physicians was founded by *one* physician; the restrictive and ignorant charter of the College of Physicians was framed by *one* physician; yet we are told by Mr. WILLCOCK,\* that the College to this day can exercise legal control over the whole of the medical and surgical practitioners of this metropolis and the parts adjacent. Although

\* The Laws relating to the Medical Profession; with an Account of the Rise and Progress of its various Orders. By J. W. Willcock, Esq., Barrister at Law. London: J. and W. T. Clarke. 8vo, pp. 290. 1830.

we shall prove, before we quit the subject, in this and succeeding numbers, that Mr. WILLCOCK is not correct in this opinion, it is sufficient for our present purpose to concede to him that the College, to a certain extent, even at the present hour, can proceed by law, and recover penalties against those persons who practise as physicians in this metropolis, without a license from that body. Thus the physicians of London, in eighteen hundred and thirty, are under the control of a charter of three hundred years standing, framed by one man, and granted by a king, whose whole life was devoted to the gratification of the worst appetites, and the basest propensities, incident to human nature. Had the wishes and interests of the whole profession been consulted by the sensual and thoughtless monarch, or had the whole profession interfered in framing the charter, a measure highly conducive to the health and happiness of mankind, and to the diffusion of medical knowledge, might have been the happy result of their labours; and, possibly, its provisions would not have proved altogether obnoxious to the wants of the practitioners of medicine in the present day.

Not to go farther back, the same fatal apathy pervaded the great mass of the surgical profession in the fortieth year of the reign of George the Third, when the existing charter of the notorious College in Lincoln's Inn Fields was granted by that not very sensible monarch. There was no appeal to the profession,—the surgeons generally were not consulted upon the propriety of the measure, and, unfortunately, there was no independent medical press to enforce their claims. That charter, which contains the horrid prescription for forming the self-perpetuating council, was conceded to eighteen *disinterested* petitioners, who of course, with the greatest generosity imaginable, and with the sincerest desire to benefit their brethren of the profession, introduced their own names into the charter as eighteen of

the councillors, who were to hold their appointments for life; at the same time, kind souls! reserving to themselves the power of electing the other three to complete the number of twenty-one. Having mentioned LINACRE as the projector of the physicians' charter, it may not be useless or uninteresting to record the names of those very liberal and learned surgeons to whom the practitioners of the present day are indebted for the *surgeons'* charter. Mark them well, reader! But it is due to the four first names that they should stand apart from the others: Cline, Dundas, Earle, and Keate—Heavyside, Cooper, Blicke—Chandler! Long!! Warner!!! Lucas!!!! S. Howard!!!!!! Wathen!!!!!! J. Howard!!!!!! Birch!!!!!! Hawkins!!!!!! Forster!!!!!! and Sir William Blizard!!!!!!

Here is an association of names! The reminiscences excited by so resplendent a collection, are almost too dazzling for our feeble intellects; but, alas! resplendent only in the vivid characters, traced by partial and purchased friends; for, in the dark and dreary vistas of the College halls, the features of those to whom they belong and have belonged, are only discoverable upon the hideous front of that many-headed monster—Monopoly. The charter, then, having been granted only at the request of a few, to a few only has it proved beneficial; in fact, it has created and promoted a more vile monopoly in a branch of medical education, than was ever concocted or encouraged in any department of the meanest trading corporation. If the combined profession had applied to the king or the legislature in a body, no such unjust, tyrannous instrument, would ever have scourged its members, or disgraced the laws of England.

The "Apothecaries' Act" of 1815, was another boon proffered to corruption by corporate jobbing and partial legislation. Several years before that act received the sign manual, the surgeon-apothecaries throughout the kingdom felt that both they

and the public required some protection against the destructive proceedings of unprincipled and mercenary quacks. They held various meetings, and endeavoured to act in concert; but there was no journal, no means of harmonizing their discordant opinions. Project upon project was suggested, and no sooner suggested than abandoned. Anxious to obtain power, a few were for establishing a *fourth* corporation, adding another to the three which had so long persecuted the profession. Observing the dilemma in which the reformers were placed by the knavish interference of the Colleges of Physicians and Surgeons, the Apothecaries' Company stepped into the arena, and by hypocritical promises of peace and justice, at once framed measures for warring against the interests and respectability of the whole profession. Never was an act obtained by more disgraceful means than that of 1815. The College of Surgeons meanly promised to offer no opposition before the legislature, if *their* privileges,—that is, the privileges of the *twenty-one*, were left untouched; and the College of Physicians disgracefully pledged itself not to oppose the bill, if *their* privileges,—that is, those of the “fellows” and “licentiates,” were left unmolested; further, these two bodies had friends, namely, the chemists and druggists, whose rights were not to be interfered with, between whom and many of the councillors of the College of Surgeons and of the fellows of the College of Physicians, a percentage co-partnership had long existed. We blame not the chemists and druggists for their conduct on that occasion. It was natural and just that they should bestir themselves in order to protect the rights and privileges connected with their trade, and upon the security of which their bread depended. But it was base in the physicians to exert themselves to deprive surgeons of those privileges which they freely conceded to druggists, and it was base in the surgeons to concede to druggists the privileges which

they resolutely withheld from physicians. The Apothecaries' Act, then, was altogether a partial measure, and utterly unsuited alike to the wants of the profession and to the public. Thus we have a physicians' “charter,” a surgeons' “charter,” and an “Apothecaries' Act,” each obtained by a few individuals, who, the moment their requests were granted, ceased to have any interests in common with their professional brethren.

The discordant elements, in constant motion by the clashing interests of three corporations, furnish never-ceasing causes of animosity and jealousy between the members of the respective bodies; and there will be little of harmony or little of justice, until we possess one great, comprehensive, legislative enactment for the government of the MEDICAL REPUBLIC. An Aristocracy in medicine can no longer be endured. Those members of the profession who now claim for themselves all the honours and dignities, exist only by sufferance; the source of their value is to be found in their impotence, and their reputation only in the most preposterous conceit.

We shall resume this subject, and follow it up, until there be laid before the profession a scheme for the formation of A NATIONAL COLLEGE.

---

*A Treatise on the Venereal Diseases of the Eye.* By WILLIAM LAWRENCE, F.R.S., &c. &c. London, John Wilson. 1830. 8vo. pp. 336.

It is only within the last few years that the venereal diseases of the eye have been well understood and appropriately treated; and although much scattered information respecting them is now to be found in various works, a complete treatise on the subject cannot fail to be acceptable to the profession, especially when coming from such a surgeon as Mr. Lawrence, than whom no one could be more fitted for such a task. Considering, however, that there were few new or disputed points to be established,—that the phenomena of each disease are in

almost every case essentially the same, and that the treatment is to be guided more by general principles than by particular indications, we may be allowed to doubt the expediency of inserting so many cases, since they tend to fatigue the reader, without affording him more information than he might have derived from a much smaller number.

Veneral diseases of the eye are divided by Mr. Lawrence into two heads,—gonorrhœal and syphilitic. Under the first he includes acute and mild inflammation of the conjunctiva, and inflammation of the sclerotic, sometimes extending to the iris; and under the second, iritis and ulceration of the lids. On the nature and origin of acute purulent gonorrhœal ophthalmia, a difference of opinion has existed. By some writers it has been attributed to metastasis, by some, to direct infection or inoculation with gonorrhœal matter, and by others to both these causes. Mr. Lawrence, while he admits the last, doubts the occurrence of the first; and where direct infection is improbable, since he has never observed the urethral discharge to be stopped on the accession of the ophthalmia, is inclined to refer its occurrence to the state of the constitution, without being able to point out in what that state consists, and to regard it as a pathological phenomenon analogous to those successive attacks of different parts which are observed in gout and rheumatism.

“The two other forms of ophthalmic inflammation,” says he, “which take place in conjunction with gonorrhœa, show themselves only in rheumatic subjects, and generally in connexion with other arthritic sufferings; and the difference between one of these and the affection now under consideration is only in degree. This view of the subject may throw some light on the circumstance, that though direct infection operates equally on both sexes, the gonorrhœal ophthalmia said to originate in metastasis, seems to be confined to the male. The state of constitution, whether hereditary or acquired, which leads to gout and similar affections, is much less common in women than in men, and will hardly be found at all in those young and previously healthy females who are the principal subjects of gonorrhœa. Again, the morbid influences which are experienced and exerted by the male urethra, are different from those of the vagina,”—p. 35.

With regard to diagnosis, Mr. Lawrence

admits, that as far as the local symptoms are concerned, there is no difference between gonorrhœal and common purulent ophthalmia, except that the former is more violent and rapid in its progress, and less frequently attacks both eyes; and that its peculiar nature can only be inferred from the circumstance of gonorrhœa existing with, or preceding it, or the patient having been exposed to the contact of gonorrhœal matter. This is, however, of little consequence, since the two affections require the same kind of treatment. In this Mr. Lawrence relies chiefly on copious and frequent bleeding, both general and local, and has but little confidence in mercury, observing, “I have seen both the ordinary purulent and gonorrhœal ophthalmia proceeding apparently unchecked under the full mercurial action. Beer expressly asserts that mercury is of no service, and the testimony of Delpech is strong to the same effect.” Tartarised antimony is not mentioned in the general account of the treatment, but it appears to have been used as an auxiliary in several of the cases related, though not to any great extent, or with very marked benefit. The ordinary local means he considers of course merely as palliatives, and as having no power of checking the disorder. Of the astringent plan, or the employment of strong solutions, of nitrate of silver, or sulphate of copper, which is stated to have been used so extensively and successfully by some army surgeons, he does not appear to think very highly; he has employed it only in two cases, and those of the mild form of the disease, and thinks that at an early period, before the cornea is affected, the ordinary antiphlogistic treatment is more safe and certain, and that afterwards the astringents in question are useless or injurious. As he does not consider the disease ever to depend on metastasis, he of course does not think it necessary to make any applications either of a stimulant or emollient nature to the urethra, and after mentioning the opinion of Scarpa, Beer, and Richter, who are all in favour of such a practice, observes,

“In spite of the confidence which one is inclined to repose in the practical knowledge and judgment of those whose advice has just been quoted, I cannot help thinking that the measures in question have been recommended rather on theoretical grounds

than from experience. At least these writers do not mention any results of their own practice; nor have I met with any cases in which the employment of such means is mentioned. In none of the instances which have come under my own observation, has the gonorrhœal discharge been suppressed, so that the reason for this kind of practice has not existed. Again, when the violence and rapidity of the disease are considered, in contrast with the slowness and uncertain operation of this treatment, we cannot doubt that irreparable mischief would be done to the organ during the time lost in such attempts."—p. 50.

The "mild gonorrhœal inflammation of the conjunctiva," though made the subject of a separate chapter, differs only in degree from the preceding; it of course requires a less energetic treatment, and may, in most instances, be "safely and advantageously treated by the astringent pla—"

In the third form of gonorrhœal ophthalmia, which is characterised by great pain and intolerance of light, the conjunctiva is scarcely affected; the sclerótica is the principal seat of the disease, which sometimes extends to the iris, producing deposition, occasionally of an arthritic character; sometimes to the cornea, inducing haziness and opacity. Here also the abstraction of blood is the principal remedial means, but blisters are more servicable than in the purulent ophthalmia, and colchicum may be given with advantage, when it is accompanied (as it often is) by inflammation of the joints, or other rheumatic symptoms.

The diagnosis of syphilitic iritis is much easier than that of the affections just spoken of. The increased pain at night, the angular disfigurement of the pupil, and especially the deposition of lymph in tubercular masses, serve to distinguish it in most cases from the idiopathic form of the disease; occasionally, however, some or all of these symptoms are wanting, and the distinction can be made only by reference to the previous or co-existing diseases of the patient.

Syphilitic iritis has been observed by Mr. Lawrence in conjunction with papular, pustular, scaly, and tubercular, eruptions, and he considers it as one of the secondary symptoms of venereal disease, and never caused by the use of mercury. In reference to this point he observes—

"An opinion has partially prevailed that the use of mercury is capable of producing

iritis. Some have considered that syphilitic iritis, as well as other secondary symptoms, either are rendered more frequent and severe by the employment of this remedy, or owe their very existence to it, while others have spoken of iritis generally as being caused by it. I have seen no instance of iritis, of whatever kind, in which there has appeared to me any reason for ascribing the occurrence of the complaint to this cause. In nine of the cases related in this paper, iritis came on where no mercury had been taken previously to its appearance, and in some of them the complaint was severe, and produced consequences injurious to vision; in others, mercury had been administered only in small quantities, and the mouth had not been made sore; and there is not one in the whole list in which the remedy had either been employed for a long time, or affected the system severely. Iritis occurred in some of the cases which had been treated by Mr. Rose and Dr. John Thompson without mercury. Dr. Ekström, of Stockholm, informed me that he had seen many similar instances in the patients of an institution where the use of mercury in syphilis had been entirely abandoned for a long time. Iritis took place in a woman who had contracted syphilis from suckling a diseased infant, and had taken no mercury."—p. 165.

The treatment of this very serious and often rapid disease, consists principally in the employment of active depletion, mercury, and belladonna; and although the last may sometimes be omitted, neither of the two first can be so, without incurring considerable risk. In several of the cases related by Mr. Lawrence, little or no impression was made on the disease by very copious bleeding, both general and local, in conjunction with other antiphlogistic means, and yet its progress was instantly checked, and a healing action was induced, when the mouth was affected by mercury; in others, on the contrary, severe and continued salivation had no good effect, and yet immediate relief was afforded by the loss of blood. The practical conclusion therefore at which Mr. Lawrence has arrived, after ample experience of the complaint under every variety of treatment, is,

"That iritis generally, and the syphilitic form of the complaint particularly, will be most advantageously treated by the successive or combined employment of antiphlogistic means and mercury; that this plan will give the quickest relief, will most effectually arrest the inflammation, restoring the iris to its healthy structure and func-

tions, and will afford the best security against the return of the disease."—p. 181.

The beneficial action of belladonna is almost entirely mechanical, preventing by the contraction of the iris the occurrence of adhesions between its posterior surface or internal circumference, and the capsule of the lens; or breaking through such adhesions after they have been formed; and the friction of mercurial ointment with opium upon the brow, though sometimes efficacious in relieving the pain, can hardly be supposed to have any direct influence on the progress of the disease.

The removal of effused lymph from the iris under the action of mercury, has generally been attributed to increased activity of the absorbents. Mr. Lawrence thinks, "that it has no such direct operation, and that the removal of these depositions takes place in consequence of the inflammation to which they owe their origin being arrested." This cannot, however, always be the case, for morbid depositions in the eye, as well as in other parts of the body, have disappeared under the use of mercury, some time after the inflammation which had produced them had entirely ceased. Of turpentine, as employed by Mr. Carmichael in this disease, Mr. Lawrence states, that he has had no experience; and though he has made a short extract from this gentleman's work, showing the manner in which it is to be employed, and observes, that the cases there related exhibit the powers of the remedy in a very favourable light; he does not give any opinion as to its probable efficacy in general.

Syphilitic ulceration of the eyelids, with the account of which the book is concluded, is a much less common affection, and does not appear to have been particularly noticed by any other writer on syphilitic diseases. It affects all the tissues of the eyelid, which it sometimes totally destroys, and may be either chronic or acute, having in the latter case a "phagedenic character, with red margin, sharp edge, foul unequal surface, on which bloody points are seen, and being attended with severe pain." It is very distinct, both in its progress and appearance, from cancerous ulceration of the palpebræ, the only disease with which it could possibly be confounded, and is most quickly and effectually cured by the free use of mercury.

*Medical Literature in central Africa. Timbuctoo Monthly Journal, No. 28.* Blackamoor and Co. October, 1830.

We have been favoured with the 28th No. of a monthly medical and surgical journal, published lately at Timbuctoo, in which, in a review of a work on consumption, the critic states (p. 299): "Chlorate of potash is not the best mode of employing chlorine;" and in a subsequent sentence, that "Medicines taken into the stomach can have little, if any, effect on diseases of the lungs.

These sentences afford strong presumptive evidence that the works of Laennec or Davy have not yet found their way into the interior, and that tartar emetic and ipecacuanha are unheard-of remedies in pneumonic affections. Massa Blackamoor, we fear, "ve pren vera mun o' him pillo-orical beefor nigger vera mun save pissick."

## LONDON MEDICAL SOCIETY.

October 18, 1830.

Mr. CALLAWAY in the Chair.

### LIABILITY OF SEROUS TISSUES TO ERYSIPELATOUS INFLAMMATION.

THE opinion that erysipelas can attack only the skin externally, and, when seated internally, the mucous membranes, is held by some of the members of this Society to be unsound; but though the point has often been agitated it has never been satisfactorily discussed. The chief supporter of the opposite doctrine, however, Dr. WHITING, having been urged to bring it fairly before the Society, took advantage of some cases which had lately occurred to him, tending, in his opinion, to show that the inflammation in puerperal fever is erysipelatous, and this evening detailed his views on the subject.

It had long been supposed (he observed) that erysipelas was a disease of the skin only, and in systematic writings it had always been classed among the cutaneous diseases. He had himself long considered this to be correct, but several cases had lately fallen under his observation, which had convinced him that the erysipelas which attacks the skin may, by extension of the inflammation, encroach upon other textures. The cellular tissue was affected by the inflammation dipping into it, and forming abscesses which burrowed in various directions, differing from the common phlegmonous inflammation. There were many cases in which also the mucous and muscular membranes were

attacked. During the last season he related a case of inflammation which began in the throat, from thence proceeded to the ear by the eustachian tube, crept by the lachrymal duct to the eye, and finally spread in the form of erysipelas over the face. Now that case did not strike him at the moment in the same point of view as that in which he now regarded it. The patient was attacked with severe dyspnoea, and the inflammation which ensued immediately after, progressed onwards until it destroyed life. This, he had thought, was owing to the state of the brain, but he now believed that erysipelas would really extend to the lungs and occasion death. He had a patient who, a week ago, was attacked with severe inflammation on the surface of the tonsils, with great enlargement. The next day the swelling subsided, and the inflammation appeared to be passing away, when a difficulty of swallowing was experienced, lower down. Leeches and blisters were accordingly applied, and the pharynx was relieved, but then the patient complained of an affection of the bronchial tube; presently the upper lobe of the lung was attacked, producing pleuritis and pneumonia, with spitting of blood. The inflammation shortly after, left the upper, and descended to the lower lobes, the patient experiencing very great pain; it subsequently passed through the diaphragm, and had that day reached the peritoneum, thus presenting the erratic tendency of erysipelas, and characters of the same description as those of puerperal fever, the connexion between which and erysipelas it was his intention to show. He had seen many such cases as these, but not knowing that erysipelas would spread itself internally in this manner, he had not adopted an explanation on the ground which he was now disposed to assume, that the erysipelas of the skin would spread from one surface to another, or from one texture to another, until it either expended itself, or destroyed the patient. Now, the question was, might he consider that he was borne out in the doctrine that puerperal fever was erysipelatous? They all knew that puerperal women were attacked by two diseases, both of the abdomen. The one was remediable by antiphlogistic means; the other would go on, despite that treatment, which, indeed, rather did harm than otherwise. In what then did the difference between these two diseases consist? It might be said,—in the difference between the constitution of women. But how was it possible to believe this, for whether the women were weakly or strong, whether they lost blood or not, still the disease would prove fatal. There was certainly nothing in the constitution to determine the nature of the disease, and he decidedly thought, therefore, that the difference in the two diseases was

rather to be ascribed to two distinct causes than to any thing else. The general opinion was, that puerperal fever was contagious, and this view was entertained by the most industrious observers and the best informed men. Dr. Gordon who first wrote on the subject, said that he could positively foretell whether the patient would have it, merely by knowing who was the attending midwife or nurse. He said that he was scarcely ever mistaken in this. This alone would lead him to say that there was some peculiarity in the cause. Dr. Gordon stated in his work that he would not venture positively to assert that puerperal fever and erysipelas were of the same specific nature, but he was convinced that they were analogous in some respect, for these two epidemics, in some instances to which he referred, began about the same time, kept pace together, arrived at their acme together, and ceased at the same time. Dr. Gordon had pointed out other reasons in favour of this conjecture, and similar views were entertained by Mr. Hey, Drs. Mackintosh, Hamilton, and Campbell, to whose works Dr. Whiting referred.

These things, then, seemed to lead to the opinion that there was something similar in the causes which led to the production of erysipelas and puerperal fever. Otherwise why were they both contagious, and why, as it was well known they did, did they both happen together? The small-pox and measles, the small-pox and scarlatina, and many other diseases might be simultaneous, but this was the result of accident, which clearly was not the case with the other diseases. As to the morbid appearances, he had examined a vast number of patients who had died of true puerperal fever, and he had always found as much difference between the inflammatory appearances and those of common inflammation, as there was between erysipelas and common inflammation of the skin.

Now erysipelas was erratic. It generally began in the womb, then proceeded to the groin, then to the umbilicus, and then perhaps went to the chest. It did not shut up the bowels like common puerperal fever. It did not require strong medicine. Taking the average of cases, there was not the same hardness and strength of pulse. There was seldom occasion to use the lancet; indeed its use was rather contra-indicated. The state of the tongue was not the same; it was not so dry nor so loaded in erysipelas as in common peritonitis. Then again, it could not be stopped so easily. It might be mitigated, but a week or ten days would elapse before it was completely cured. With regard to the *post-mortem* appearances, when inflammation of the common character had lasted ten days, it was usual to expect to find adhesions. Now he

did not mean to say that there were no adhesions in the true puerperal fever, but there certainly were no organised adhesions. He had examined this point minutely, but he had never been able to discover any thing beyond mere agglutinations. Neither were there the same appearances in the cavity of the pelvis. Instead of the effusion there deposited being a clear, semi-transparent fluid, it was a muddy, dirty serum, with flakes like the curd of cheese. With these remarks he should presently introduce a case to their notice, which had fallen under the care of himself and a surgeon who was now present. He would also refer to a case mentioned to him by Mr. Greenwood, where it having been necessary to pass a catheter in consequence of retention of urine, inflammation came on two days after the operation, and extended to the peritoneum, presenting all the characters of puerperal fever. Mr. Travers also removed some excrescences from the verge of the anus, where erysipelatous inflammation came on, spread up the rectum, and speedily assumed all the appearances of puerperal fever. The case, however, to which he now wished to refer, was that of a middle-aged lady residing on the other side of the water, whom he had attended in child-bed. She bore two children, and suffered a severe rigour; reaction came on, and a pain commenced in the region of the womb, which became very tender, and enlarged. What was to be done in such a case as this? The variety of treatment recommended by practitioners was so great, that he did not know to what measures to resort; he thought it right, therefore, to read all the authors from whom he could expect to obtain information on the subject; accordingly he referred to Gooch, Hamilton, Armstrong, Gordon, Mackintosh, and Campbell, and made up his mind that antiphlogistic measures would be the most successful. Dr. Gooch was the last writer on the subject, and he recommended that the patient should be bled to syncope; twelve hours, therefore, from the first attack, this (or nearly this) was done; leeches were then applied: she was purged from the first; three grains of calomel every three hours, with a quarter or the eighth of a grain of tartrate of antimony, and one grain of opium. She recovered, but the progress was slow; there was a gradual *subsidence*, but not what might be termed a *removal*, of the pain, which ceased, however, before it reached the diaphragm. He had attended another patient who was moribund, and apparently past every chance of recovery; as a last hope he gave ammonia, and the patient suddenly revived. In this case he believed that the inflammation was running its course, and stopped just short of life, when the ammonia was administered.

In these cases the blood was buffed, and the mercury carried to pytalism.

The speaker having thus submitted a general outline of his views to the members, Mr. Hooper read one of the cases of puerperal fever, to which Dr. Whiting had referred. It did not present any features farther illustrative of the doctrine, and Mr. Waller, Dr. Ryan, and Mr. Dendy, expressed an opinion that the case was one of acute inflammation of the uterus.

The replies which were made may be stated in few words.

Mr. PEREIRA considered it impossible, according to the received definition of the term erysipelas, that erysipelas of the peritoneum could occur. The same disease *in principle* might perhaps exist there, but vesication, an essential character of erysipelas, could not take place in the peritoneum. Dr. Whiting had relied for one of his proofs upon the erratic character of the inflammation in the cases he had related; but, by a parity of reasoning, rheumatism must be considered to be erysipelatous also. Phlegmonous inflammation was an inflammation of the cellular structure terminating in abscess, but the inflammation which in the cellular tissue was called phlegmonous, must, in serous membranes, if it could occur there, be called by some other name, a consequence which must be fatal to the position of Dr. Whiting.

Dr. RYAN also differed from Dr. Whiting, who, he said, had only referred to authors on one side of the question. Dr. Ryan had attended cases exactly similar to those of Dr. Whiting. He had bled the patients generally, and applied leeches and blisters without benefit, but after having given up the case as lost, he had tried calomel and opium, and procured recovery.

Mr. DENDY coincided in most respects with Dr. Whiting, and in reply to Mr. Pereira's first objection, said it must be remembered that though the effusion in inflammation of the peritoneum was not deposited between two tissues, yet that it was deposited in the abdomen.

Dr. BLICKE, and one or two other gentlemen, made some observations on the treatment of puerperal fever, but the hour of closing the meeting having by this time arrived, the discussion here closed. Dr. Whiting and Mr. Hooper pledged their judgment that the disputed cases bore exactly the characters of malignant puerperal fever.

#### DOCTRINES OF INFLAMMATION.

Since our report of last week was written we have taken some pains to collect the particulars of the discussion which occupied the members on the first evening of meet-

ing, as it formed a continuation of the debate with which the last session closed.

The subject in dispute involved the merits of certain pathological opinions formerly advanced by Mr. Stephens; namely, First, that pus formed in the course of disease was not a secretion, but rather a conversion of parts, perished or disorganised by disease, into a fluid matter, and Secondly, that inflammation was not, as is supposed, an agent of disease, but an agent of restoration only. In support of the former of these opinions, Mr. Stephens cited the example of a scrofulous gland, which when about to suppurate might be felt softening, and resolving into a fluid rough matter, first in the centre, and gradually through the whole tumour. It was in the failure of nature's power to absorb the tumour, that she threw it off in the form of fluid corruption. He contended that this was a more probable and more natural process than the one commonly supposed, where, previous to suppuration, the tumour was said to be taken up by the absorbents, and matter secreted in its place. If the tumour was absorbed the cure was effected, and there was no need of suppuration. In support of the latter opinion, Mr. Stephens drew an analogy between fever and inflammation. In fever there was a certain effect produced upon the body, by some morbid agent, whether contagion, miasma, or any other cause, which, whether it operated by contaminating the blood, producing internal congestions, or in whatever way, required a reaction of the vital powers to get rid of the cause or its effects, and this reaction was the fever; and the same he believed occurred in inflammation. Inflammation he believed was the reaction of a part against some disease or injurious agent affecting such part; he believed that it was quite distinct from the disease itself, and he differed from modern pathologists, who seemed to consider inflammation, whenever it occurred, as the sole diseased agent. He believed it to be a restorative agent only.

The arguments used in opposition to the former of these opinions by Dr. Blicke, Mr. Lloyd, and some other gentlemen, were, that pus was often discharged from cysts, which had been emptied, and from sinuses, which it would be difficult to account for upon the supposition of a conversion of surrounding parts into pus. Mr. Lloyd also stated that it was not the gland itself which enlarged in scrofula, but a deposit of white caseous matter, surrounded by layers of adhesive matter, which formed the enlargement, and which was afterwards discharged as pus.

The answer to these objections by Mr. Stephens was, that he did not think it was solid parts only which became converted into pus; he believed, in the case of sinuses

or cysts, that there was a perpetual attempt at organisation in them, and that the fluids and matter deposited for such purpose were thrown off as abortive, and became converted into pus, or dead matter; he also argued that Mr. Lloyd's description of a scrofulous enlargement favoured his opinion, as it showed that it was the original tumour which was discharged as pus, and not a fresh secretion.

The opposers of the latter opinion, amongst whom were Dr. Whiting, Mr. Proctor, and one or two other gentlemen, argued that Mr. Stephens's opinion condemned the treatment of inflammation altogether, and if such ideas were entertained, what were we to do in the treatment of disease? Dr. Whiting asked Mr. Stephens how he would explain inflammation of the lungs produced by a common cold, upon his principles. Cold had produced the inflammation, but when the inflammation was produced what had we to do with the cold? What had we to treat but the inflammation?

In reply to these various objections, Mr. Stephens stated that he did not wish it to be understood that inflammation was not to be opposed by any treatment; he believed that the reaction or inflammation of a part was almost always to an excess, and of course required control; but he did not agree with modern pathologists, who seemed to think if they could prevent inflammation from taking place altogether, or could quell it at its commencement, they would get rid of all disease. He believed that in every case there was a cause existing, visible or invisible (like contagion), which excited and supported the inflammation; with regard to cold producing inflammation of the lungs, and that when produced, the inflammation was all we had to combat, the cold no longer existing, he argued that the cold had produced certain effects upon the lungs, whether of congestion, interruption of the function, &c., or some other injury which required a reaction to remove it; he believed that inflammation of the lungs was never cured upon the principle of quelling all action; it had a natural cure, namely by expectoration, and the remedies inducing this were the true remedial measures; further, to explain, he would suppose a piece of wood thrust into the flesh, and the surgeon overlooking this, contenting himself with combating the inflammation only, what would be the result of his treatment, compared with that of one who looked upon the piece of wood as the injurious or diseased agent, and removed it? The inflammation under the latter treatment, would require no combating, it would die away of itself; he believed, in all cases, some cause produced some effect, whether of functional

derangement, contamination (like vaccine virus applied), or congestion, for the removal of which the reaction or inflammation was established.

[The above forms a condensation of the arguments employed in the discussion of this subject.]

#### GANGRENE OF THE LUNG.

The following case of well-marked gangrene of the lung was read by Mr. HOWELL in the course of last session, and intended to have been included in a report of the proceedings in No. 343, but was mislaid.

I was sent for in the evening of the 5th of August, 1829, to Mr. G. G., aged 26 years, and learnt that he had been indisposed for several days, and had applied leeches, and taken physic, but had not been visited by any medical man. I ascertained that he had been very feverish, and had suffered much pain and tenderness in the lower part of the right side of the abdomen; that he was very restless and occasionally sick. The pulse was under a hundred, and not very characteristic of active inflammation. Upon examining him more particularly, I found he had pain and tenderness in the right renal region, extending through the abdomen in the course of the ureter. The urine was small in quantity, high-coloured, and, upon standing, deposited a large quantity of uric acid. He had pain in the hips passing down the thighs, but had never any retraction of either testicle. The bowels had been readily and actively purged. I concluded that he was passing some calculi from the kidneys, and that consequent irritation had produced inflammation in that part, perhaps extending to the ureter. I bled the patient moderately, and was particularly struck with the exhaustion the loss of a small quantity of blood seemed to produce; I directed such medicines as I thought proper, and that he should be fomented. On the 6th I found him in every respect better; the blood presented but very slightly those marks denoting inflammatory disease. On the 7th he complained of a recurrence of pain, and the symptoms of disorder of the urinary system; was again sick and very restless. The pulse justifying me, I abstracted more blood from the arm, and applied a dozen leeches to the lower part of the right side of the abdomen in the situation of the *caput coli*. These measures effectually relieved him, and for several ensuing days the only inconvenience he suffered was from occasional vomiting, for which he drank abundantly of effervescing medicine. On the 18th he had again a little pain in the situation of the right kidney, which was, however, soon relieved by the

application of a few more leeches. The patient seemed to be convalescent till the morning of the 22nd, when he had a severe rigour, succeeded by heat and profuse perspiration. On the following day he had another rigour, and in the evening it was repeated. The 24th was passed without one, and the patient suffered only from debility, and very considerable irritability. From the occurrence of the first rigour I had given him quinine; and it may be important to observe that he was repeatedly seen during his illness by Mr. Callaway, who must have observed as well as myself, that the patient had no cough nor any dyspnoea, neither did I ever find his pulse above 100 beats in the minute. Remembering these circumstances I was astonished to find in the morning of the 25th that the evening before he had been suddenly attacked with an inclination to spit up something, and that by slightly coughing he expectorated a large quantity of diffuent greenish pus, emitting the most distressingly offensive odour. The pulse had become accelerated to 120, and possessed a very peculiar character, described by Mr. Callaway "as if the muscular power of the artery had ceased to act." The countenance had assumed an anxious character; the skin and eyes were yellow, the former had a peculiar, moist, glassy appearance. The patient was lethargic, and disinclined to conversation, but upon any allusion being made to the state he was in, he expressed his confidence of ultimate recovery. In this alarming state of matters Dr. Thomas Davies of New Broad Street saw the patient; the pathognomonic signs of his case were then as follows:—Fætid expectoration, puriform, and occasionally tinged with blood; slight cough, but no dyspnoea unless disturbed; absence of respiration in the inferior half of the right lung, with slight rale crepitant, and dullness of percussion. Dr. Davies gave his opinion that the disease was gangrene of the lower lobe of the right lung. A continuation of augmented doses of sulphate of quinine with an expectorant and a light nutritious diet was advised. Suffice it to say, the plan was anxiously and carefully pursued for several days, but the expectoration continued, retaining its offensive character, the patient rapidly declined, and died on the evening of the 3rd of September.

The body was examined early next morning, Dr. Davies, Mr. Callaway, and myself, being present. There were old adhesions of the upper part of the right lung, the upper lobe of which was healthy, whilst the inferior was filled with a dark bloody serum, yielding a gangrenous odour; an irregular cavity in the inferior lobe of the right lung, about the size of a walnut, parietes dark, lined by a thin false membrane of some firmness, and filled by a thick, dark, grumous

matter, of a fœtid odour; adhesion of the diaphragmatic face of the inferior lobe with the diaphragm. The left lung was adherent to the costal pleura, but otherwise perfectly healthy.

## ST. THOMAS'S HOSPITAL.

### CLINICAL LECTURE

DELIVERED BY

DR. ELLIOTSON,

Oct. 18, 1830.

#### PLEURISY.

On Thursday last, Gentlemen, twelve patients were received into the hospital under my care; six of them men, and six women. Of these cases, there were among the women, one of acute pleurisy, one of chronic bronchitis, two of peritonitis (one of them rather a chronic or subacute case, the other acute but partial), one of dropsy of the whole of the body, with peritonitic ascites (ascites and peritonitis), and one of hemiplegia.

Among the men were three cases of rheumatism, one of chronic inflammation of the hip after a strain, one of incipient universal palsy, or double hemiplegia, one of disease of the spine and chronic dysentery.

From amongst these I shall select the case of pleurisy, and one of the cases of rheumatism; my reason for fixing upon both, is, because the chest is remarkably affected in this rheumatic case, and the two will form both a good comparison and contrast, it being sometimes difficult for a young practitioner to distinguish between pleuritic and rheumatic pain of the chest,—between pneumonia (using the word in a general sense) and rheumatism of the external part of the thorax. The case of pleuritis occurred in a woman of the name of Lydia Poole, aged 56, a charwoman by occupation, of a spare habit, who had been ill two days before her admission on Thursday. According to her account she has been subject to cough and copious expectoration for the last thirty years. On Tuesday, the 12th inst. she was employed in washing and scouring, and went to bed at night quite well. In the course of the day her feet had got very wet, and at night after she had been asleep about an hour, she awoke with a pain in her left side which was increased on inspiration. On Wednesday she experienced alternately great heat and cold, shiverings and flushes, and her habitual cough and the pain in her side increased. She was so alarmingly ill on Thursday that her friends brought her to

the hospital. I found her in bed, a short time after her admission, and she was then complaining of a violent stitch in the left side in the situation of the seventh, eighth, ninth, and tenth ribs. Her cough was very frequent, very short, and agonising, so intense did it invariably render the pain in the side; her respiration also was quick and short.

The "stitch" was increased by moving in bed, and the least pressure made her exclaim with pain. On applying the stethoscope to the left side, I found that the respiration was not so distinctly to be heard there as it was on the other side, where no pain was felt. The pulse was 104, and rather wiry, that is, rather small and hard; the skin was hot; the tongue white; she was very thirsty; the bowels had been freely open the day before from medicine.

Now this, Gentlemen, was a very well-marked case of inflammation of the pleura, and as such I bring it under your notice. In the first place it was clear that she laboured under an internal inflammation. The pain increased by pressure and every mechanical cause that could be applied,—deep inspiration, which would stretch, and cough which would shake,—and the pyrexia, the feverishness, the heat, thirst, and quick pulse, proved this. That this inflammation was seated in a serous membrane, was shown by the pungent, stabbing character of the pain, as though a knife were plunged in, and the firmness of the pulse: that this serous membrane was the pleura, appeared by its seat on the side, below the breast, where, or at a level with the breast, the pain of acute pleurisy is generally felt. In pleurisy, also, you always have, as in this woman, a short cough, and it is short, because to cough deep would give intolerable pain; the disease irritates to coughing, but the patient is compelled to restrain the cough forcibly. The cough is usually dry, because the seat of irritation is the pleura, not the secreting surface of the bronchiae and air-cells; or if not dry, the expectoration is scanty. In the present case the cough, though short, was loose,—the expectoration copious, because she laboured under chronic catarrh, and the pleuritic cough necessarily discharged the copious mucus of the bronchiae. The breathing was very difficult. This is necessarily the case in pleuritis, though it may arise also from ten thousand other causes. The difficulty in this case arises from the pain which is experienced by stretching the pleura in attempting to breathe deeply. The patient cannot make a full inspiration, for very agony; the breathing, therefore, is shallow, and to compensate for the shallowness of the inspirations, they become more frequent. The countenance was expressive of extreme anxiety, the features

were lengthened ; the face had a leaden hue, in consequence, I presume, of the combination of the chronic bronchitis, which had existed for so many years, with the inflammation of the pleura. Altogether, I may say that no case of pleuritis could possibly have been better marked than this, with the single exception of the copious expectoration of this early stage, and for which I have accounted.

With regard to the seat of pain, this was in the usual situation. But sometimes it is not felt on a level with, or just below, the breast on the side, but in the axilla and other parts ; and sometimes, instead of being seated in one point, it is rather diffused all over the side ; and in very severe cases, has been felt over both sides.

It is generally noticed in this disease that the patient rarely lies on the healthy side, and the reason, without doubt, is, that if the patient lay on the side which is not affected, the expansion of that half of the chest would be very much lessened, and a greater degree of expansion therefore required on the affected side when inspiration is made, and thus great pain occasioned. The patient, therefore, usually rests on the affected side, or rather towards it, that it may not expand so much as the healthy side, and may, by this less expansion, suffer less pain. It is often not possible to rest on the affected side, on account of its tenderness. In these instances a diagonal position is taken, such as will permit the healthy side to take the greatest share of expansion, and prevent the diseased side from expanding extensively, and yet not occasion compression of it. I mentioned to you also that there was, in the present case, a great increase of pain on pressure between the ribs. This does not always happen in pleuritis ; but here it was so, and the patient therefore lay in a diagonal posture. Where, however, this is more decidedly the case than in the present instance, I have known it to be impossible for the patient to lie even towards the affected side, and they have been compelled to rest entirely on the other, and the very pressure of the bed-clothes, when heavy, has been nearly unbearable. Had there been no other symptom than this, the extreme agony produced on pressure between the ribs, would have led me to decide that the pleura was affected, and this indeed led to a still more minute diagnosis,—that not merely the pleura, but the pleura of the ribs, the pleura costalis, was the seat of the affection, not that the pulmonary pleura might not be also inflamed, but that the costal pleura unquestionably was. Viewing all the symptoms together, you must perceive that nothing could be more easy than the diagnosis in the present case.

The pulse is, in general, very charac-

teristic of inflammation of a serous membrane. It was not indeed so hard as I have often known it in inflammation of these membranes, but it was rather hard ; and you know that among the variations induced in inflammation by structure, the hardness of the pulse is always mentioned as marking the disease in the serous membranes. There is certainly a variety in this respect ; I have known it to be full and soft, and small and weak ; but, for the most part, it is disposed to be hard and firm. In this case the state of the pulse was not so marked, that it alone would have led me to conclude that inflammation of a serous membrane existed. It was of the true character, but yet not decidedly pronounced.

The quality of the expectoration in pleuritis is usually glairy, and the quantity is small. I have already explained why, in this case, the mucus was abundant and thick. On visiting her just now, I found her free from all signs of pleurisy, but she says her cough is as troublesome as ever, and that she expectorates freely ; in truth, she is in her habitual state, as well as before the attack of pleurisy began. Indeed, she would not allow me to consider for one moment the cough which was present, because it was so habitual as to be to her of no moment, when compared with the symptoms from which she has been liberated.

On the subject of employing the ear in this disease, I must state that the case was made out perfectly without listening at all to the chest ; but no one can be perfectly acquainted with pleurisy or any other disease of the chest, without knowing whether any changes, and if any, what changes, occur in the healthy sounds of the thoracic organs. The history is imperfect without them. I listened in the present case, and found that there was less respiratory murmur than natural in the affected spot. As this deficiency arose from only the imperfect expansion of the lungs through the pain of full inspiration, percussion would, no doubt, have produced the natural hollow sound,—the part containing air as usual, though not expanded to the usual extent. But percussion is not always admissible in these cases when there is tenderness ; and it was not so here, in consequence of the violent pain on pressure. The knowledge to be acquired by this mode of diagnosis, is not commensurate with the degree of suffering occasioned to the patient, and it ought not to be tried. Notwithstanding the clearness of the case, however, I used the stethoscope, that I might be enabled to communicate to you the exact auscultatory state of the parts, and to learn if there were effusion or not. If effusion had been present, the respiration would not have been heard so distinctly as it was, or not at all. The

sound of the voice, when listened to at the side, would have had a nasal twang, a resemblance to the voice of Punch, or to the bleating of a goat, as is observable when a thin layer of fluid is poured out upon the lungs; it is, in fact, altogether so much like the bleating of goats, that the term *ægophony* was given to it by Laennec, from *αἴ* a goat, and *φωνή* sound or voice. This symptom was not discovered; no effusion therefore had taken place in even a moderate degree, and the presence of respiration showed that it had not taken place in a high degree.

So much as to the history and diagnosis of this woman's case. With regard to the causes, one may readily suppose that in consequence of the previous existence of chronic bronchitis the organs of respiration were more predisposed to inflammation than they would otherwise have been. The most common exciting cause of pleuritis is to be found in the action of cold, especially combined with moisture, upon the body when the individual has been over-heated. There can be no doubt that such was the case with this woman, that she had been over-heated in her work, when her feet got wet. The feet thus exposed, are a most common medium by which inflammation of distant parts is excited.

As to the cure, nothing can be more beautiful than the treatment of cases of acute inflammation. The body is more subject to inflammation than to any other disease, and no disease is more dangerous; while on the other hand there is no disease in which medicine can be employed more satisfactorily. If the diagnosis was perfectly clear in the present case, the treatment necessary to be pursued was equally so. I had the woman made to sit upright in bed, and ordered her to be bled, not to this quantity or to that, but to fainting, and as soon as that was over, twenty leeches were applied over the seat of pain, and after them a poultice. I ordered five grains of calomel, with three of opium, to be given at the same time, and the calomel to be repeated every six hours afterwards. The next morning, I found her able to lie perfectly well on the left side, learnt that she had slept soundly all night, though she had not slept a wink the night before, and was entirely free from pain; she had scarcely any cough remaining; she could take a deep inspiration, and bear pressure on the part; in fact, she complained of nothing whatever. The original chronic catarrh only remained. I learnt that venesection had produced syncope, which lasted in an imperfect degree for about half an hour. The pulse was certainly 96, but it will remain high sometime after the disease is materially lessened. It was not so firm as before, but soft:—not, however, weak. The tongue

was moist. I need not say to you that of course the blood was buffed; the whole mass of the coagulum was buffed. It was not cupped, but, without doubt, if it had been drawn into a tea-cup, it would have been cupped. The cupped appearance is materially influenced by the size of the vessel into which the blood is drawn. If disposed to cup, the smaller the vessel the more decided will be both the buffiness and the cupped appearance; our bleeding basons are not favourable to tonic observations upon the blood. I saw the woman again on Saturday, and she was then still better; her mouth was by that time becoming rather sore. As there had been no stool since her admission,—24 hours having elapsed, I ordered her on Friday some castor-oil; not for the purpose of purging her, but to prevent any irritation of the bowels which costiveness might occasion; this operated once or twice the same day, and again on Saturday morning, and since that time she has made no complaint; she has indeed been convalescent, excepting a certain degree of debility, the effect of a thirty years' bronchitis, and a slight soreness of the mouth.

I need hardly say to you, that in acute inflammation, the very best treatment that can be adopted is to procure a loss of blood from a vessel of some size; and further, that on the suddenness with which the bleeding is performed, its good effect materially depends. If you suffer it to dribble from a vein, you do no more good than though you applied leeches. The larger the orifice, the quicker the operation; the shorter the time employed in it, the more decided will be the impression made upon the system, and the greater the benefit derived to the patient by the loss of a given quantity of blood. There are one or two things to be observed in performing it. Where, for instance, you wish to save blood in some degree, you should place the patient upright in the bed. The loss of less blood will then produce syncope, than of a larger quantity in the horizontal posture. But in cases of considerable fulness of the system, the great object is to produce fainting by taking away a full quantity, and not to bring on that state until a considerable loss of blood has been obtained. As the patient was an old woman, I was anxious not to abstract more blood than was absolutely necessary; and yet sixteen ounces were drawn before she fainted. In some cases, where no fulness of blood exists, there is so great a disposition to faint, that there is a great chance of fainting taking place before a proper quantity is abstracted; and here, again, it may be right to bleed in the horizontal posture. On the other hand, where it is desirable to remove the smallest possible quantity, the patient should be bled standing, and then very few ounces will fre-

quently cause him to faint. In the treatment of acute inflammation, having made your diagnosis, and ascertained how much blood can safely be lost, you should go briskly to work, knock the disease on the head at once, and then follow the bleeding up immediately with the other necessary measures. Sometimes a single bleeding will answer the purpose, sometimes not; but at any rate local bleeding, resorted to instantly afterwards, will often prevent a second general blood-letting from being necessary. It was not until the leeches were applied in the present case, that the greatest relief was obtained, but it immediately followed their application. I may say, that it is frequently a very good practice to assist unloading the vessels of the inflamed part after general bleeding, by applying leeches or by cupping. I mentioned to you, that I afterwards directed a poultice to be laid on. You will find this a very beneficial plan after leeches; it encourages the bleeding, and has likewise a very soothing effect.

The other remedies employed were calomel and opium. From the age and constitution of this patient it was desirable to avoid a necessity of repeating the bleeding, and therefore I was particularly desirous of producing more or less affection of the mouth, and of fully tranquillizing the system. The use of opium is frequently very beneficial after bleeding. It is not so perhaps where there is a full habit, or the head is affected; but when we see reason in the constitution to spare bleeding, and where we fear any morbid irritability from the loss of blood, then opium is an advantageous medicine. Under these circumstances I have never known opium to be injurious after bleeding. It tranquillizes the system, secures comfortable repose, and is thought to render subsequent bleeding less necessary. It acted, or appeared to act, most beneficially in this case; at least we are certain it did no harm,—did not aggravate the symptoms: the patient fell into a quiet and long sleep, and awoke free from complaint, even from cough. The opium may not only have procured the quiet night, but prevented, or assisted in preventing, for what I know, a return of the inflammatory symptoms; so that, although it did not produce the cure, it had some share in the general beneficial effect. With regard to the mercury, I do not attribute the removal of the disease at all to it. It *may* have assisted also in preventing a return of the symptoms, but I cannot say that it really did—that they would have returned but for its exhibition; but a failure rarely occurs, when it is employed in addition to bleeding, and other suitable means. The good effects which I always have seen to result from producing tenderness of the mouth by mercury

in active inflammation, induced me to give it; and if this woman were attacked again next week, I should pursue in all points the very same practice, though I do not now venture to say, nor do I believe, that it had any share in the removal of the disease. In single successful cases of inflammation, in which mercury is given, we are not justified in referring the benefit to its effects; but I have drawn my conclusions from contrasting two series of cases: the one treated by the ordinary antiphlogistic measures only, the other by the ordinary antiphlogistic measures, and mercury pushed on to some degree of affection of the gums; and I know that the success was infinitely greater in the latter. In my practice a free exhibition now always forms a part of the plan, and a failure in subduing active common inflammation is a very rare occurrence, a thing scarcely ever met with by me, unless there has been organic disease at bottom, or I have been called in too late, or been obstructed in doing what I wished—I have often repented of having trusted to ordinary measures, but never of having given mercury in addition. Nothing is more common than to see the symptoms yield the instant that the mouth is affected, or to find all necessity for further bleeding no longer necessary from that moment. I may also observe, that the administration of calomel with the opium tended to enable a subsequent purgative to act. Had I not had the constitutional effect of mercury in view, I should have exhibited one dose with the opium, to obviate constipation, and ensure the operation of a purgative, if necessary, the next day. After the third dose, the calomel was discontinued, although no affection of the mouth had taken place, because really the disease was at an end, and further treatment was not necessary; for although I would always act vigorously, I would never act unnecessarily. Respecting the leeches, I think it is very probable, if not certain, that if, in this case, the leeches only had been applied, the disease might have gone on from that day to this, instead of being suddenly subdued, or not been subdued at all; we might have pushed the disease about, but not have knocked it down. If recourse had not been had to leeches, a general bleeding might have been necessary again the same night, or the next morning. There is nothing like knocking disease down at once if you can, and keeping it down by subsequent measures. How far the opium assisted in the latter purpose I cannot assert.

To learn whether there is any effusion, I have just examined her. The respiratory murmur is natural on the affected side, and there is no ægophony; there is therefore no effusion. Some of the gen-

tleman present probably recollect the case of a girl who was affected with pleurisy, and treated in the hospital during the summer months. The case was more severe, as the pain was more extensive, and the case lasted longer. The patient was cured in the same manner, but for some time her voice sounded most laughably, exactly like Punch, at the back of the chest on the affected half, and on the lower part of the same side; yet the pleuritis had ceased. Suddenly copious sweats burst forth, and the Punch-like sound as suddenly declined, and soon ceased altogether. Here effusion had taken place, and the absorption occurred simultaneously with excessive secretion by the skin. The case was remarkable. As the full respiratory murmur, and the absence of oegophony, show that no effusion has taken place, the present case is a good instance of the termination of inflammation by resolution, without suppuration, effusion, gangrene, or any fresh circumstance or symptom, but in perfect health of the part. In the most favourable termination of inflammation, there is generally some increased secretion in the part itself, or the surrounding parts; but here there appears to be none—there is pure resolution.

#### RHEUMATISM OF THE CHEST.

THE other case, which I introduce to your notice by way of comparison and contrast, is one of rheumatism of the chest. The pain was not in the same situation, but was rather severe.

W. H., aged 19 years; he had been ill a fortnight before admission. At first he had suffered from rheumatism of the left knee, and now complained of the left shoulder, but particularly of pain in the region of the acromion. He experienced great pain on respiration all over the front of the chest,—a sharp pain; and pressure greatly aggravated it, so that he started back as soon as the end of the finger touched any part of the front of the chest, as he did when it was applied over the acromion. Now this might have given the idea that he was labouring under pleuritis, but the complaint was easily distinguished from that disease. Certainly to one who had not seen the two, a difficulty might arise on meeting with such a case. But, in the first place, the slightest pressure on the chest gave pain,—such slight pressure as could not affect the pleura; and pressure not merely between the ribs, but gentle pressure with the end of the finger on the ribs and sternum, in a place where the pleura could not have felt the pressure. The pressure which distressed the woman was made between the ribs. If pressure upon the ribs ever produce pain in pleuritis, it must be very strong, unless in the worst

cases, when all the symptoms mark the nature and danger of the disease. In the next place there was great heat of the surface of the chest. There was, also, rheumatism of other parts,—the knee had been affected before the chest, and there had been sweating,—so usual a thing in acute rheumatism. The pain, too, was not in one spot, but diffused. Lastly, there was not the general illness of the system which was observable in the woman; the man was not even confined to his bed, and there was neither cough of any kind nor expectoration. The dyspnoea was inconsiderable, compared with that of the woman. Now the combination of all these symptoms was such as enabled me readily to infer the nature of the disease. All but one of them, however, are subject to doubt. The diffusedness of the pain is sometimes, though rarely, observed in pleuritis. Rheumatism of some part may occur at the same time with pleuritis; nay, the rheumatism in the chest and elsewhere may be so active, that considerable pyrexia, heat, thirst, quickness of pulse, whiteness of tongue, considerable general illness, may occur in mere rheumatism, so that the patient may keep his bed. There may also be a catarrh, so that cough, short or not, may exist and be attended by expectoration, little or much. The extreme tenderness on such slight pressure, and on pressure made where it could not affect the pleura, proved the external seat of the disease, and the rest of the symptoms harmonised completely with this observation; so that taking the whole together, I had no doubt upon the subject.

The treatment of the two diseases requires to be conducted on the same principles; yet there are two reasons why a careful diagnosis is necessary in this complaint. First, a true diagnosis will enable you to inform the patient, and his friends, with truth, whether the disease is dangerous or not; for pleuritis is dangerous, while the rheumatic affection of external parts is not; and secondly, although the same measures are necessary in each case, they are not required to the same extent in the one as in the other. The vigorous measures demanded in pleuritis are seldom necessary in mere rheumatism. In this case I ordered no general bleeding, but thirty leeches to the chest, and, as the shoulder was affected, I directed some of the thirty leeches to be applied very near it; I also directed five grains of calomel to be given night and morning. The leeches completely relieved the pain in these places, but it soon flew to the opposite shoulder, and the next day it migrated to the neck, active rheumatism having always a remarkable tendency to migration. Leeches to the parts successively attacked produced relief in both places;

and but for a slight sore throat, and some pain in the right shoulder, owing to his having gone out of doors contrary to my wishes, he would be considered perfectly well.

Nothing is more useful than to examine cases together which are very similar in some points, and yet differ essentially in others, and I trust you will see the importance of the present comparison and contrast.

There has been no death during the week in my wards, and I have, therefore, no morbid anatomy to teach.

## CAUTION.

WE understand that a person calling himself VILLIERS, is travelling the country, and making heavy exactions upon the benevolence of medical practitioners, by representing that his case has been strongly advocated in *THE LANCET*, and that he is the distressed medical man, whose misfortunes were so frequently adverted to in the pages of this Journal about eighteen months back. We have good reason for believing that the fellow is an impostor.

## TO CORRESPONDENTS.

COMMUNICATIONS have been recieved from C. R. M. S.—Mr. Drew.—A Scion of Medicine.—Dr. Melhuish.—Mr. Adams.—Mr. Forbes Winslow.—Mr. John Richards.—Amator Justitia.—Apis.—Mr. Arthur Beetham.—Mr. John Ennis.—A Friend to Discussion.—Vindex.—A Friend to the Medical Student.—Mr. Knowles.—Mr. H. W. Bailey.—H. F.—Mr. James H. Morson.—“Governors and Advocates.”—Mr. Lionel J. Beale.—Mr. Bennett.

*H. M.* “The letter dated September 9th,” has not been received at our office, consequently we can offer no opinion of its contents. If *H. M.* would forward the particulars of the transaction, his questions shall receive immediate attention.

*Bacchus.* The certificates must be produced agreeably to the regulations of the present period. The examination in Latin will consist in translating grammatically portions of Celsus and Gregory’s *Conspexus*. A certificate of the dressership will be sufficient for the College of Surgeons, but not for the Company of Apothecaries.

## LITERARY INTELLIGENCE.

Professor Seerig of Breshaw will shortly publish the first part of “Anatomical Demonstrations, or a collection of Colossal Representations of Human Anatomy;” and Dr. M. J. Weber of Bonn is preparing for the press “An Anatomical Atlas of the Human Body. Part I., embracing osteology, including two skeletons of the natural size.”

## BOOKS RECEIVED.

*The Philosophy of Sleep.* By Robert Macnish, Mem. of the Fac. of Phys. and Surg. of Glasgow. Glasgow: W. R. M’Phun. 12mo. pp. 268.

*The Dublin Hospital Reports and Communications in Medicine and Surgery.* Volume the fifth. Dublin, 1830. Hodges and Smith. 8vo. pp. 631.

*Elements of Chemistry.* By Andrew Fyfe, M.D., F.R.S.E., &c. Second Edition, comprehending all the recent discoveries. Edinburgh: Adam Black, 1830. In one vol. 8vo. pp. 1062.

*Deadly Adulteration and Slow Poisoning; or Disease and Death in the Pot and the Bottle; an exposure of the various Adulterations of Food and Medicine, &c.* By an Enemy of Fraud and Villainy. London: Sherwood. 18mo. pp. 187.

## CLINICAL LECTURES

DELIVERED AT

St. Bartholomew's Hospital,

By MR. LAWRENCE,

October the 15th and 22nd, 1830.

### NEVUS MATERNUS.

OCT. 15. MR. LAWRENCE, on Friday, made the following observations on a case of *navus maternus*, occurring in Susanna Marsh, an infant about sixteen weeks old, at present in Faith's Ward.

*Navus maternus*, or "maternal spot," is a name given to certain peculiarities which are vulgarly supposed to have their origin in the "longings" of the mother. This *navus maternus* is a disease of the capillary vessels of the skin, or *under* the skin. From the mother's information, it seemed, that at the time of birth, the only appearance of the disease in this child was a small red spot, which has, however, so rapidly increased in size, that now, at the distance of only fifteen or sixteen weeks, the *navus* extends over the whole of the left side of the face. The tumour feels soft and doughy, and yields upon being squeezed, but swells out again on relaxation, like a sponge. *Nævi*, in fact, consist almost entirely of blood-vessels, so interwoven as to form a complete congeries. The effect is, that the blood contained in them is easily forced out by pressure, on the removal of which the elasticity of the vessels restores them to their usual size, and the blood returns. The tumour feels exceedingly warm, which might readily be conceived, in consequence of the quantity of blood circulating through it, but the heat in this instance is much less considerable than it frequently is. The tumour is covered by integument in the natural state, save on the upper parts about the eyelid, where it assumes a dark livid hue; and in some places the surface is of a finely granulated texture. Now the *navus maternus* is not always of the same texture throughout. Sometimes cutaneous *navus* is found

existing in the skin, and elevated a little above the surrounding parts, or beneath the skin, and this is consequently named the *subcutaneous*. Sometimes there are spots of that peculiar, livid, vascular, texture before mentioned. These may remain stationary, or they may grow rapidly, and then cease to increase. Frequently, however, they require immediate and vigorous treatment, and this is especially the case in the present instance. These *nævi*, when left to themselves, may exist for years, but neglect would be very dangerous, on account of the large blood-vessels which supply them. These vessels, ramifying near the surface, are exposed to numberless chances; they may get divided in a fall, especially in children, and considerable hæmorrhage would be the consequence. If, then, the risk be so great, the question is, What are the best remedial means for us to adopt, and what can be safely done in the case? The prognosis, in general, may be founded on the magnitude of the tumour, and the age of the patient. It has been proposed, when these growths are very large, and when situated in the neck, to tie the carotid artery. There is a gentleman, at present in this metropolis, from the United States, Dr. Massey, who had a case of *navus maternus* occurring in the scalp. He tied the carotid on one side, and that having no effect, and the growth continuing, he resolved to cut off the scalp, and an awful operation it was; but the patient is now doing well. Excision is a plan that is sometimes adopted, but in making use of it you must cut freely round the tumour, and taking the utmost care not to cut into the structure, for you can have no conception of the alarming loss of arterial blood which would be occasioned thereby. When he spoke of *arterial* blood, he should remark, that it is by no means determined whether the vessels of these *nævi* be veins or arteries. Sometimes, from the livid purple colour of the tumour, one is led to suppose that it is caused by a venous circulation. He had lately been attending a lady for this affection, in whom, from the dark colour of the surface, it seemed reasonable to suppose that the tumour contained *venous* blood, but there the blood that issued was decidedly

arterial. With regard however to the practice of excision, it is certainly dangerous, if the supplying vessels be large; and they are sometimes so large that the patient has even died on the operating table from the hæmorrhage.

Since, then, the danger of this method is so great, it remains to consider what other means are to be adopted. Now it has been said, that a cure may be effected by exciting inflammation in the part, and thus obtaining an obliteration of the vessels; but unless an obliteration of the whole could be procured, of course the inefficiency of this treatment is obvious. A caustic, *Kali purum*, has been recommended, but he doubted whether the use of it is advisable. However, he adopted this method in the case of the lady before mentioned; he touched every point of the tumour; indeed, he said, he took the greatest liberties with it, to excite a sufficient degree of inflammation, but without success. There is an article in a number of a northern medical journal on this subject (see LANCET, No. 362, page 723), the author of which, Mr. Fawcington, states, that he has met with great encouragement to insert a seton in these cases. He relates a case of two years' duration, in which he made use of this agent, and he informs us that the result was the consolidation of the tumour. He had himself tried this method, but he confessed he did not find it of much service. With regard to the child at present in the Hospital, the only treatment he had as yet adopted is that of applying cold. Caustic he should be unwilling to employ, on account of the great size of the nævus, and, on the whole, he really would rather not meddle with it at all. If it could be brought to a stationary condition, he certainly should be inclined to let it take its own course. If, however, it continued to increase, something must be done to check it.

Oct. 22.—Mr. Lawrence said, he had alluded to cases of nævus maternus, in which it had been found practicable to remove the tumours by ligatures,—instances in which the swelling lay in dangerous situations, and where, by the application of the ligature, a cure was effected without the danger of the tremendous hæmorrhage which occasionally proved fatal, even at the moment of operation. Various modes, he said, had been devised for producing inflammation in the substance of the nævus, and thus obtaining consolidation; one of these consisted in the employment of the vaccine virus in the nævi of children who had not undergone previous vaccination; here the object was to introduce the matter extensively over the tumour, and in its circumference; for this purpose twenty or thirty, or even more punctures were usually made, and in his own experience he had

known the practice to be of some efficacy. Some time since he had a child under his care, in his private practice, with a small cutaneous nævus on the scalp about the size of the end of his thumb. On the whole he considered this a favourable case for the trial, and the operation was accordingly performed. Inflammation supervened to a considerable extent, and as it declined a thick hard crust formed over the tumour, and as that was removed the nævus was nearly though not entirely gone. This occurred about a year and a half since, and he then requested the parents, who were persons of consequence, to bring the child to him again should there be a recurrence of the affection; he had not since heard of them, and he therefore considered it a rational conclusion that a cure had been accomplished. He had known of another case in the country, where a child was affected with a large subcutaneous nævus on the side, which had been vaccinated, as he was informed, with considerable effect; the swelling had been originally round, and of a deep purple colour throughout; it was now much diminished in size, a great part of it was entirely consolidated, and in the centre it had become of a natural white appearance. On the whole, if not entirely reduced, the swelling had certainly been permanently diminished.

The vaccination, however, could only be applicable, as he before observed, to patients who had not previously been subjected to the specific influence of that virus. At present he has a lady under his care who has a large nævus on the face. She had originally a small growth under one of the eyelids, and this has gradually increased to its present extent. Its boundaries were now, the ridge of the nose, the anterior part of the ear, the ciliary margin of the lower eyelid, and a line drawn from the angle of the lips towards the ear. Three considerable lobes were remarkable in this tumour, one corresponding to the lower eyelid, the second much larger beneath this, and the third still larger below both. Altogether they formed a considerable protuberance; the circumference of the swelling was of a livid colour. As the lady was in other respects of a handsome person, and the removal of this deformity of course a very desirable matter, she had come a considerable distance for advice; excision or ligature was out of the question, and he passed in the first instance, a thick seton through the inferior part of the tumour; the seton was introduced by a large needle with a proportionate thread, in order to prevent the risk of hæmorrhage, which was thus obviated, and not more than a dozen drops of blood were lost in the operation. No inflammation followed, and he next sprinkled the seton with a little powdered nitrate of silver, and drew it into the opening; beyond

pain and irritation this produced little or no inflammatory effect. The nitrate of silver was again used more copiously, and a great deal of uneasiness was produced for twenty-four hours without the supervention of any general inflammation. The seton was then removed, and he introduced a stick of caustic-potash into the opening and rubbed it in very freely, and he thought that if any-thing could induce inflammation, this certainly would; accordingly it did occur to a certain extent, the tumour diminished somewhat in size, and there was some consolidation; he afterwards applied the kali purum externally, freely over two parts of the tumour; a partial cure was thus effected, but on the whole the inflammation was by no means so general as the extensive irritation might have been expected to induce. This case, Mr. Lawrence continued, showed decidedly the difficulty with which these tumours were inflamed, and that in general they might be dealt with with great freedom. He might say that the usual opinion that inflammation was generated through these tumours with facility, was incorrect; that in one situation inflammation might be carried even to the death of the part, without extending any further. In the present instance he had destroyed the upper part of the tumour by a ligature, he would try the same with the lower part, and eventually treat the edges with strong nitric acid.

#### PLETHORA FROM THE SUPPRESSION OF LOCAL DISCHARGES.

Mr. Lawrence next called the attention of the class to a specimen of blood which exhibited strongly the ordinary characteristics of that fluid when drawn in acute internal inflammation; the coagulum was firm, deeply cupped, and covered with a buffy crust; yet it had been drawn from a patient in whom no external evidence of an inflammatory nature existed at the time of its abstraction; in fact, it was taken by the person's own desire, by his own prescription, and the appearance it now wore certainly showed that he had not erred much in his diagnosis. The man was in "Henry Ward," where he had been confined for some weeks with a fractured leg. He (Mr. Lawrence) did not see him until he had been a considerable time in the hospital, as Mr. Lloyd was then in charge of his patients; he was about 50 years old, of full, plethoric, make, and he believed of rather jolly habits. After admission there was considerable inflammation of the limb, and on reference to his papers, it was seen that, besides general bleeding, an almost countless number of leeches had been applied to the limb, and he had been on milk diet, which, as containing but comparatively lit-

tle animal matter, could scarcely contribute to the excitement of inflammatory action. He was admitted on the 27th of July; he had been bled, purged actively, treated with digitalis, and leeches, and leeches, and leeches, over and over again, but the inflammation, notwithstanding, ended in suppuration, and a copious discharge ensued, which, within a short time, rapidly diminished, and the openings healed. A few days after this, the patient felt himself heated and full, especially about his head; these symptoms he very properly ascribed to "too much blood," and not as patients generally do, "to weakness," which is, in other words, a wish for animal food, and beer or spirits. The man considered himself in a state of plethora, and was bled.

It had frequently happened to him, he observed, in this hospital and elsewhere, to see patients who had laboured under profuse local discharges become plethoric, and prone to determinations of blood and internal inflammations when these discharges were suddenly suppressed. This he had seen over and over again under such circumstances in old running ulcers of the leg, more especially if the patients were placed on animal diet and allowed beer, and these determinations would proceed to every degree, up to fatal apoplexy. There was a patient now in "Henry," who was in the Hospital some years before for inflammation and ulceration of the leg; it was rapidly healed, and in a few days he had a sudden and violent attack of apoplexy; the usual treatment was adopted; he was profusely bled, cupped, leeches, purged, and blistered, but with so little effect, that he (Mr. Lawrence) abandoned all hopes of his recovery; as a last experiment, however, he determined on the employment of mercury in large doses, which was pushed to salivation, and he eventually recovered; but for a long time he was paralytic on one side, and even at present his mouth was somewhat distorted. He had now been seven weeks in the house for a recurrence of the ulceration, and during this time, according as the ulcers were healing, it had been found necessary to bleed him repeatedly, in order to counteract the return of a similar affection to that from which he formerly suffered. The hospital diet table, he was sorry to say, was any-thing but judicious; the "ordinary diet," for example, consisted of animal food, two pints of good strong beer—not table beer, but much better—with several other good things. As it is on this diet that a patient is placed on admission, and as it may happen that a patient may not be seen immediately after entrance, and meanwhile may labour under acute inflammation, this diet would, of all other things, be the best calculated to aggravate his disease. He

had, therefore, made it a general rule, that his patients should be placed, at first, on milk diet, for if they were in a condition for beer and meat, the hospital was not the fittest place for their reception.

#### ERYSIPELAS.

Two or three cases of erysipelas (Mr. Lawrence continued) were at present under treatment, to which he would now direct their attention. The first was that of Olive Moore, æt. 28, in "Faith Ward," a straw-bonnet maker, unmarried, whose menses had been suppressed for the last three months, a circumstance which contributed much to predispose her to inflammatory attacks, and had already given her the appearance of a general plethoric habit. She was admitted on the 20th, and stated, that since the 17th her face had been swelled and painful, and that her illness commenced with shiverings, succeeded by increased sweatings.—There was considerable tumidity of the right cheek, extending a little towards the left; the eyelids were closed, the tumour generally of a deep-red colour, pitting on pressure, and acutely painful. There was also great general disturbance; the pulse 120, hard and full; the tongue coated; bowels confined; headach; great thirst; skin dry and hot; she had a slight attack of the same kind the preceding winter. She was bled immediately to eighteen ounces, and the blood was of a highly inflammatory appearance, as if it had been drawn in acute pleuritis. She was ordered a mixture, with a drachm of sulphate of magnesia and half a drachm of the solution of tartrate of antimony, every sixth hour.

On the 20th, the inflammation was rather increased and more extended towards the left side; bowels had not been opened, and she was generally worse. Venesection to fourteen ounces was directed, and the senna mixture; the blood was again cupped and bled; she was also ordered two grains of calomel and two of antimonial powder, every six hours, and the ordinary saline mixture. By these means the headach was considerably relieved in the evening, and at nine p.m. she was altogether better, and that night she slept well.

On the 21st, the inflammation had not increased, but there was a recurrence of the headach on both sides; the pulse was rather fuller and harder; she was cupped to twelve ounces; since then she had continued better, and was, on the 22d, in every respect much relieved; the swelling had subsided without vesication, and desquamation was commencing; he had desired the saline mixture to be continued. In this case, Mr. Lawrence said, the inflammatory nature of the affection was strongly manifested by

the general symptoms and the condition of the blood, which was certainly as strong a characteristic of inflammation as it could be, if drawn during inflammation of any internal organ. If attention were paid to such cases as this, no doubt of the real nature of the affection could be entertained, and so much would not be heard about the use of wine and bark in this disease. He supposed this treatment was grounded on the occurrence of erysipelas in aged and debilitated persons, in whom, certainly, the depleting treatment would not be justifiable, notwithstanding that the local symptoms were originally inflammatory to a certain degree. It was in every case necessary to discriminate between the essence of the disease and the persons in whom it occurred.

There was, in the same ward, a young woman named Robinson, who had been admitted on the 19th with a slight degree of redness, and some swelling, of the leg, but whose case did not at first receive particular attention. To-day (23d) it had become excessively painful, and she was in a state of violent febrile excitement and constant agitation; the leg was internally of a bright scarlet, or, rather, crimson colour; externally the inflammation was also very active, and the colour was insensibly shaded into the unaffected parts; the inflamed parts were also much swelled, and she complained of violent burning pain. Such was her state in the morning; besides, her skin was hot and dry; pulse quick and strong; she had headach, white tongue, and was extremely restless,—all symptoms characteristic of great constitutional disturbance. This instance also showed the highly inflammatory nature of the disease. A large bleeding was immediately directed, and leeches to be applied to the inflamed parts; the saturnine lotion, and active purgative medicines, were also prescribed. Before the leeches were applied she was accordingly bled to deliquium; thirty leeches were afterwards put on; the effect of this treatment was the almost immediate tranquillization of the local and general distress, and when Mr. Lawrence went into the ward just before lecture, he found her in a calm and sound sleep, from which she was not aroused by his being present.

In the same ward the case of Richardson afforded an example of what might be termed "*phlegmonous*" erysipelas, in contradistinction to the other cases which might be denominated "*simple*," in which the tumefaction proceeded only from an affection of the true skin, and consequent effusion, and not from inflammation of the subjacent cellular tissue; in the phlegmonous form the swelling was firm and resisting, and did not pit so readily as in the simple kind. In Richardson's case Mr. Wood had very judi-

ciously made one incision down the whole length of the swelling. It would be found that such incisions were by far the most effectual means of treatment in phlegmonous erysipelas, and of terminating satisfactorily the local symptoms and general disturbance. When erysipelas is accompanied by inflammation of the subjacent cellular tissue, it frequently evinces a disposition to spread; the adhesive inflammation, in other words, does not intervene to arrest its progress; in these cases free incisions are also by far the best means of counteracting the disease. In the first place they occasion a copious flow of blood from the inflamed parts, the vessels bleeding with infinitely greater energy than is observed in ordinary wounds of the same extent; but the relief is not solely attributable to the bleeding, for an equal quantity abstracted by other means will always fail to produce an equivalent effect. The incisions, however, operate most effectually, by relieving the great distension of the parts; the limb, previously red and shining, becomes pale and wrinkled, and the pain is almost immediately abated. In the present case the incision operated in this manner; the spreading of the local inflammation has been arrested, and the patient now only labours under a simple healthy wound.

#### ACUTE HEPATITIS, TERMINATING IN SUPPURATION.

He had occasion once or twice to notice the application of the same principles of treatment to internal and external inflammations. There were at present some cases in the wards which illustrated this analogy further. In "Henry" there was a patient named George Booth, æt. 39, admitted with a large phlegmonous abscess over the right hip, and who also laboured under hepatitis. Generally speaking, one inflammation was as much as the animal economy could undertake at a time; but, in this case, two were in action. He had been unwell about a fortnight before admission, but could assign no cause for his illness. He said his hip had been "lanced" by a doctor, but nothing followed but blood. As he felt a deep fluctuation, he introduced the lancet a little further, and a copious discharge of pus immediately followed. Still the relief was not so great as might have been expected; the skin was sallow, his features contracted, and he complained of pain in his right side. On uncovering his abdomen, the cause was at once perceptible; he breathed entirely by his ribs, and studiously avoided the exercise of the abdominal portion of his bellows. These appearances, coupled with great abdominal pain and other usual indications, at once proved the nature of the

affection. It was not, however, one of such a dangerous character as is sometimes seen; in fact, in these climates, the termination of acute hepatitis in suppuration is comparatively of infrequent occurrence. He was bled to sixteen ounces. Had jalap and calomel, and a saline mixture, with tartar emetic and sulphate of magnesia, every sixth hour. He was moreover cupped once, and had a blister to the side. He continued taking one grain of calomel and five of jalap till his bowels were effectually relieved, and till it was considered the purging had been carried to a sufficient extent. Active as this was, however, none of the bad consequences were produced on the intestinal mucous membrane, of which our brethren on the other side of the channel seemed so much afraid.

Under this treatment the man had nearly recovered. In these cases he would again repeat, that the same principles of cure which referred to external inflammation, were also applicable to those of internal parts. There were some other patients then under treatment which further illustrated this position, but of these he would speak at the next lecture.

#### INQUEST AT HAMPTON.

LETTER FROM MR. MORSON.

*To the Editor of THE LANCET.*

SIR,—Anticipating some comments would be made from the report which you gave in your publication of the 9th October, of the inquest held at Hampton on the 2nd, I purposely delayed offering any observations before, anxious to ascertain first the feelings of that respectable body of men denominated "General Practitioners" from the result of the case in question, the practice of one of whom, it appears, in the instance of Mr. Bowen, has recently most unjustly been called in question, and, as far as I am capable of giving an opinion, been made the subject of unmerited animadversion.

Previously to my noticing any portion of the report taken at the inquest, and embodied in No. 371 of your LANCET, I must pause for a while to express freely the surprise and indignation which I felt on perusing a letter from Sir Andrew Halliday (physician to the Duke of Clarence), published in your 372nd Number, and in which I find he has endeavoured, but in a very pitiful manner, to exculpate himself from what he would wish others to regard, as merely "an apparent inconsistency," in reference to his original assertion to Mr. Sells, of Kingston, and that afterwards made

to Mr. Taylor. The conduct, Sir, lately practised by Sir Andrew throughout the whole of this most unpleasant affair, I can have no hesitation in pronouncing, to have been perfectly at variance with the criteria by which *I have been taught* to estimate the conduct of truth and honour; and he himself must be well aware, that I am not singular in this opinion, or without proof "as strong as holy writ" to justify it. I now, Mr. Editor, boldly call upon Sir Andrew to account for the five different assertions which he made, respecting the removal of the arms of the child, and the non-delivery of the woman. 1st, To Messrs. Sells and Taylor; 2nd, To Mr. Jackson; 3rd, To Mr. Bowen and myself; 4th, To the Coroner and jury; and 5th, After the inquest, in the letter which he addressed to Mr. Taylor; no two of which, I do assure you, Sir, in the least correspond. Thus far, I trust, I have adduced enough to satisfy you, and your enlightened readers, that Sir Andrew's conduct savours of something more than "apparent inconsistency." Also, that the assertion which he has since made in your Journal, accusing others of having used "great efforts to implicate him personally," is, like the rest of his statements, wholly without foundation.

Already I fear, Sir, you will consider me as trespassing largely upon valuable pages, but as you have afforded space for the attack, you will, I hope, in justice, grant a similar favour for the defence.

It was not until the morning of the 26th August, that Mr. Bowen was apprised of what (as since proved) had been secretly hatching for a month before. At this time Mr. Kent, an inhabitant of Hampton, at the request of the minister, called on him to say, that his attendance was required at the residence of Mr. Jackson, where the parish authorities were sitting in council. Mr. Bowen, notwithstanding this *very brief notice*, having had no prior intimation that such meeting was to take place until an hour after the witnesses had assembled, readily obeyed the summons, when, on arriving at the field of action, to his great surprise he was informed, that his presence had been requested to answer to the charge of improper treatment towards the late Frances Clarke, who was represented to have died, a month previously, in the pains of labour, during his attendance upon her. This charge Mr. Bowen was likewise informed, was preferred against him by Mr. Sells, a surgeon at Kingston, who, without giving him any antecedent notification of his intentions (although they had met each other *frequently* after the death of the deceased), had applied to a magistrate to take cognizance of the case. Mr. Cowe, of Sunbury (the magistrate applied to), not deeming himself

sufficiently authorised to interfere; recommended Mr. Sells to apply to the churchwardens of Hampton; he did so, and it was in consequence of *this application* that the churchwardens met, and convened all those persons who were in attendance with Mr. Bowen on the deceased previously to her death; when, after a patient and minute examination of each, which lasted five hours, and when depositions were recorded which materially differ from those subsequently taken at the inquest, they were induced (upon hearing a further statement of the case given by Mr. Bowen) to appeal to three eminent obstetric practitioners of this metropolis for their opinions; and as these gentlemen all agreed as to the propriety of the treatment pursued, they (the churchwardens) immediately expressed their approbation of Mr. Bowen's conduct, in a letter which this gentleman received a few days after. Thus, Sir, you will observe; that the statement in your report, which informs us "that some inquiry was entered into by the parish officers, but this only went to ascertain how far the surgeon at Teddington was culpable in declining to attend," is perfectly erroneous. The meeting was instituted for the purpose of investigating the foundation for Mr. Sells's charge, and I believe with a view also of allowing this individual, and all others interested, the opportunity of substantiating the same; but, strange to say, Mr. Sells *never came forward*; and lest ignorance of the meeting might be alleged by Mr. Guy (retained, as asserted, on behalf of Mr. Clarke) as the cause of his non-attendance, it is but justice to say, that during the sitting of the churchwardens, a letter, written by him, was received by Mr. Jackson, containing instructions, and such questions as he wished to be put to the witnesses, and which *were put*. This obvious listlessness on the part of Mr. Guy, I leave for him to explain; it must, however, unquestionably suffice to show, that he at least was *well acquainted* with what was going on, and if, as he has since vaunted, it was "ever his practice to tread lightly on the accused," why did he not *then* generously come forward, and allow Mr. Bowen the opportunity of repelling aspersions, as unfounded in their nature as they were malignant and prejudicial in their tendency? But no, Mr. Editor, this was an act of plain dealing hardly to be expected.

For the satisfaction of your readers, remote from the scene of this late disgraceful transaction, it may not be amiss to state that Mr. Bowen, the gentleman accused of ignorance and inhumanity, has, for nearly the last three years, filled the situation of visiting assistant to Mr. Davies; during this period his conduct proved always so uniformly correct; the opportunities which

he had of extending his profession were so extensive and multifarious; the satisfaction he afforded to those of every class committed to his care had been so universal; say, so beloved and well known was he throughout the neighbourhood, for mildness and assiduity in his profession, that upon Mr. Davies's relinquishing his practice at Hampton to become domestic surgeon to their most gracious Majesties, many of his patients, the greater part of whom are individuals of the utmost respectability, opulence, and rank, solicited Mr. Bowen to become Mr. Davies's successor. Arrangements for this purpose were accordingly made, and I beg it will be borne in recollection, that it was not until a few days before Mr. Davies's final departure from Hampton to accompany the King to Brighton (fully one month after the death of the deceased), that this attack was made. Hence Mr. Bowen has every legitimate right to infer, that those persons who propagated the report of his improper treatment of the deceased were influenced in doing so, by motives *other* than purely philanthropic and humane. Inasmuch as he is prepared to prove that the very witness, Ann Ellam, who bore testimony against him, declared, very shortly after the demise of Frances Clarke, to Mr. Keene, a gentleman of property residing in the parish of Teddington, and one of its overseers, that Mr. Bowen's conduct to the deceased had been most "kind and attentive." Inasmuch as Mr. Clarke, the widower of the deceased, acknowledged to a gentleman, a resident of Hampton (whose name, if required, I am authorized to give), when asked how he intended to remunerate Mr. Guy, replied, "I can only do so with my gratitude, but I have some good friends who I have every reason to hope will do so for me." Who these *good friends* are, Mr. Bowen has yet to find out, together with many other circumstances upon which "clouds, shades, and darkness, rest." These slight abstracts will, however, I hope, suffice to prove that although it has been maintained, that the proceedings which took place were instituted at the sole desire of the husband, such could not have been the case; also, that throughout the whole business Mr. Bowen has had to contend with some secret miscreant, who, like the owl which fears to prey by day, was compelled to seek for nightly cover for the execution of his base designs.

I shall now, Sir, go on and briefly offer a few additional remarks on the evidence taken before the parish officers at Hampton prior to the inquest, and that which was subsequently obtained, and since recorded in your Journal of the 9th inst. To this part of my communication I beg leave more particularly to invite the attention of your readers,

who, by contrasting both, will, I am quite assured, discover the conflicting nature of such testimony, as well as the very apparent motives which led to its elicitation.

One of the witnesses, Mary Ann Elliott, when examined by the parish authorities, on the morning of the 26th of August, stated, "that on her mentioning to Mr. Bowen that Mrs. Clarke wished to have further assistance, he *insisted* on some other medical gentleman being sent for, stating, at the same time, that there was no use of sending for any one from Hampton, as he knew there was no one at home."

Ann Ellam deposed, on oath to the coroner and jury, that when she asked the deceased, in the presence of Mr. Bowen, if she would not like to have some other medical man? "Mr. Bowen said nothing to this."

On the contrary, Sarah Chillman, the midwife, likewise on oath, contradicts the before-mentioned statement of Ann Ellam, and says that when she asked the deceased if she would have Mr. Taylor who attended her before, and when deceased replied she would, that she then told Mr. Bowen; he said, "If Mr. Taylor came, he would go out of the house."

Many more such-like discrepancies in the evidence I could wish freely to expose. But I fear, in doing so, I should only be obtruding upon your valuable time and indulgence. Let it then suffice to say, that upon the "*mens conacia recti*," and upon the decision given by that tribunal before which Mr. Bowen has lately so unfeelingly been arraigned, but which decision I regret to say was never accurately published, as will be seen from the following correct copy of the verdict—"Died by the visitation of God; and it is our opinion that the medical attendant did all that *was possible* to be done, to deliver the deceased under the circumstances"—does he *rest his claims* for future public confidence and approbation. This I am certain will not be denied him, when every circumstance is duly deliberated upon, and when it is more particularly recollected, that when called upon to render his assistance (after another had positively refused), he did so with alacrity and good feeling, that his attention during the progress of the labour was prompt and unremitting, that he left her but for a short period, and that *then* he was obliged to do so (having to visit elsewhere), the whole of Mr. Davies's extensive practice being, at the time, intrusted to his care.

Let those, therefore, disposed, Mr. Editor, to censure Mr. Bowen *hastily*, remember "He that is without sin, let him cast the first stone." I am, Sir, yours faithfully,

J. H. MORSON,  
M.B.C.S. of London.

28, Cockspur Street, Oct. 20, 1830.

## QUESTIONS TO SIR A. HALLIDAY.

*To the Editor of THE LANCET.*

SIR,—If Sir Andrew Halliday will give plain answers of *yes* or *no* to the following questions, and not twist his evidence, as Mr. Bowen appears to have twisted off one or both of the arms of the infant, the public will be able to understand what he means, and it will in some measure tend to remove the doubts that the unsatisfactory testimony given by him on the inquest could not fail to produce: it will, besides, save him the trouble of further explanations, or appeals, to the public for the purpose of correcting his errors. It is besides but an act of justice to Mr. Bowen that this fact should be clearly ascertained, whether he gave the information to Sir A. Halliday, which Sir A. afterwards communicated to Mr. Sells, Mr. Taylor, and others:—

Whether Mr. Sells ever, and when, told him “that he had been informed, by a Mr. Russell (or any other person or persons), that Mr. Bowen had taken, or torn, off the arms of the infant of the late *Fras. Clarke*, and had not delivered the mother?”

Whether he communicated this information to Mr. Bowen, and when?

Whether Mr. Bowen on that, or some other, and what occasion, did not inform him, “that the report was untrue,” and that he had not taken, or torn, off the arms of the infant, and had delivered the mother?

Whether he, Sir A. Halliday, did not afterwards, and when, inform Mr. Sells, “that he had seen Mr. Bowen, who had assured him that he had not twisted, or torn, off the arms of the infant, but had opened the head and delivered the mother, and that she died from exhaustion?”

Whether he did not make the same statement to Mr. Taylor, and request him to contradict the report of Mr. Bowen’s having done so; and whether he has not acknowledged and admitted, in some letter or letters written by him to Mr. Sells and Mr. Taylor, or one or both, and which of them, “that Mr. Bowen had informed him, that he had not taken off the arms of the infant and had delivered the mother?”

Whether he did not, at his own house, in Sept. last, inform Mr. Guy “that Mr. Bowen had told him that he had not taken, or torn off, the infant’s arms, and had delivered the woman, and that she died from exhaustion?”

Whether, on the inspection of the bodies of the infant and the mother, it did not appear that the arms of the child had been torn off from the body, and that the mother had not been delivered?

Your most obedient servant,  
AN INHABITANT OF HAMPTON.

Oct. 20th.

## LETTER FROM MR. GEORGE TAYLOR OF KINGSTON,

*To the Editor of THE LANCET.*

SIR,—It is with great reluctance that I feel myself imperatively called upon to address you for the purpose of repelling several unfounded accusations that have been, and still are, circulated against me, in the dangerous form of insinuation and report, connected with a recent investigation at Hampton. I should have treated such falsehoods with contempt, and would have confidently depended upon public opinion, and upon my established integrity and conduct through life, if a plausible colouring had not been given to one of the charges deeply involving my character.

The following are the reports to which I allude.

1st.—That I refused to give my professional assistance in the case of the deceased, though sent for by Mr. Bowen.

2nd.—That I invented and propagated a falsehood, and screened myself by attributing it to Sir Andrew Halliday.

3rd.—That I encouraged, and have been one of a secret committee or party for the purpose of getting up, a malicious inquiry calculated to injure a professional man in public opinion.

4th.—That I employed, and am to pay, the solicitor who brought the inquiry before the inquest.

These appear to me to be grave charges; and if the following refutations be not considered clear and conclusive, I invite the closest scrutiny into my conduct upon this or upon any other occasion.

To the first charge I reply, that the messenger admitted that he came to me without the consent of Mr. Bowen; and that when my answer, that I would willingly attend if invited by Mr. Bowen, was received, it is in evidence that he replied, “If Mr. Taylor came he would go out of the house.”

To the second charge; Sir Andrew Halliday swore upon the inquest that Mr. Bowen never told him “that he had not taken off the child’s arms and that he had delivered the deceased,” I do most positively assert that Sir Andrew Halliday told me (and he has by his letter since the inquest admitted the fact) that this conversation, now denied, did actually take place between him and Mr. Bowen; and Sir Andrew Halliday, at the same time, authorised me (as I believe with a kind motive) to give a flat denial to the report of the midwife, “that the child’s arms were cut off, and that the woman had died undelivered.”

To the third charge; I deny most solemnly that I have been one of any secret party or committee, for such or any other unworthy

purpose ; but I freely admit that I always entertained an unfavourable opinion of the case, and I suppose that no one, who understands any-thing of the subject, who heard the evidence and witnessed the examination of the bodies, will assert that I was not amply justified in that opinion, although I willingly abstained from expressing it at the inquest.

To the fourth charge ; I declare upon my honour, that I neither employed, nor am I to pay any-thing directly or indirectly to, the solicitor who conducted the inquiry, and who, I have since ascertained, had a written authority from the husband of the deceased to inquire into the causes that led to the death of his wife and child.

Yours, most obediently,

GEORGE TAYLOR.

Kingston, October 9th, 1830.

## WESTMINSTER HOSPITAL.

### REMOVAL OF THE HOSPITAL.

*To the Editor of THE LANCET.*

SIR,—In this day's Number you have not published the documents relative to the Westminster Hospital promised in your Number of the 9th ultimo, but you have done what, differing from you *toto cœlo* as to the merits of the case, I consider much worse, you have thrown your sword into the wrong scale, given the weight of your advocacy to the party which is, in my opinion, unquestionably the weaker in argument, as it is in numbers. Allow me a few lines in reply. Is it true that what is now popularly called the *Westminster Hospital* was "established for the benefit of the poor in its immediate vicinity?" The history of the charity published not long since in your own pages (July 17, 1830) answers No! Is the object of the "removal party, the conversion of the hospital into a medical school for the benefit of (more lucrative to) the medical officers?" No! such is not their intention. The removal will, I sincerely hope, greatly benefit the officers, for that benefit is contingent upon, and consequent to, the increase of prosperity that the charity must, from the greater prominence and convenience of its new site, quickly experience. The general interests of the charity and the private interests of the medical officers are concurrent and connected, but by no means, or rather by no necessity of things, antagonistic interests. The greater the publicity and extent of accommodation of the charity, the greater its claims on the public, and the more numerous its contributors of all kinds ; the greater also, of course, the advantages of the medical officers in reputation, in hos-

pital fees, and in every other species of emolument derivable from their appointments. The permanent and real interests of the charity and its officers recede or advance together ; they bear by no means an inverse ratio to each other, as you seem to think, but obviously, I maintain, a direct ratio. Is the site of the present hospital not an obscure one? Compare it with neighbouring subscription hospitals, St. George's, the Middlesex, where is the avenue to it like Piccadilly, or Mortimer, Goodge, or Berners Streets? possibly, for you speak confidently, you have an account of the number of fashionable or respectable equipages or pedestrians that pass within sight of it daily ; if you have, does the amount equal the one-tenth of what passes by either of the other hospitals proposed for comparison? But its present site is likely to be hereafter much more conspicuous you will say, possibly, but when? Its present site is wholesome, more so, you declare, than that to which it is proposed to remove it. How has that been ascertained? Complaints have not reached you that "erysipelas, hospital gangrene, &c., are common in the wards." "The hospital is at the corner of the Park, &c." Now I have been some time a trustee, and have officiated as house-visitor, and am well acquainted with the hospital, and I affirm that such complaints have been made, and frequently made, though probably not to the "public," by which, from your reasoning, I imagine, you must mean by something equivalent to an advertisement in the "Times" or in your own powerful Journal—the "Times," as I may say, of the medical world. Furthermore, are you not fully aware that ague and other malarious diseases, are not unfrequently generated in the vicinity of the present hospital, and more frequently there than north of Charing Cross? You object to the rent of 700*l.* or 800*l.*, demanded by Government ; are you aware that the medical officers propose to bind themselves down to pay 400*l.* per annum of that sum? You know that it is of course in the power of the trustees to accept that offer, and to bind down their successors for ever to that, or even to a larger amount. But the trustees will not do so ; it may be, it has been said, they are too blind or too indifferent no doubt to the interests of the charity to avail themselves of their power of prescribing to candidates the conditions of election ; nay, perhaps they will even make the present incumbents a present of the 400*l.*, some fine morning of the years 1830-1-2-3, or some approaching year ; will you maintain that? The increase of wealth and internal accommodation that would follow on the removal is an argument, valid, you declare, against the change of site. It is a reason why the benevolent should pa-

transfers its preference another institution, a dispensary in Villiers Street, Strand, known by the courtesy of the gentlemen of the "broad sheet," by the title of the Charing Cross Hospital. To the soi-disant Charing Cross Hospital, I bear no ill-will. It is a thriving bantling, if we can judge by its power of lungs. Its hunger-cry is heard in every quarter within doors and without, in the drawing-room and in the sick-chamber; its fosterers are many and indefatigable; at the bazaar we see beauty turn jewess for it; in the temple eloquence begs for it, piety prays for it, and wealth and avarice are shamed into contributing towards its sustenance and advancement. There is no escape or "mistake," its wants you must hear of whether disposed to contribute or not to their satisfaction. But to speak seriously; in favour of the Charing Cross Hospital much might be said, but the claims of the Westminster Hospital are of a higher order. The Westminster Hospital has long established rank amongst English charities, and has fortune to enable it at least to maintain its already ancient distinction. Why should the Charing Cross Hospital be preferred before the Westminster Hospital by the charitable? Is there not, at all events, room enough for both? Do the hospitals of London offer accommodation sufficient for one half of the sick that require assistance? Has the public ever suffered from competition? But you seem to prefer for medical and surgical instruction, small hospitals to large ones; how is that? Must not large hospitals furnish a greater number of interesting and instructive cases, and more abundant materials for necrotomic study, and for clinical teaching? Certainly. But large is a relative expression. Now a number of students so large as not to admit of sufficient investigation by each individually, without injurious and intolerable disturbance of the sick, in the present hospital where the patients, though few, are very much too many, would, in a modern hospital twice or thrice as large, cause no inconvenience whatever, either to the sick or to themselves. Each pupil of an extensive hospital cannot daily examine every interesting case. But he may carefully study (as is very usual for example in Edinburgh, Paris, &c.) every second, third, or fourth case; that is, in a large hospital every student may studiously observe the progress of half a dozen or half a score important cases. What more can you reasonably require? but I must conclude. I do not know whether I have noticed every argument you advance, but I cannot further encroach on your pages at present; perhaps you will allow me to address you again, for I have not exhausted the subject. I confidently expect from your candour and respect for justice the insertion of this letter, and

am, Sir, very respectfully, a friend and subscriber to THE LANCET,

C. M. R. S.

Tuesday, October 19, 1830.

#### REMOVAL OF THE HOSPITAL.

To the Editor of THE LANCET.

SIR,—You have said a great deal against the removal of the Westminster Hospital; perhaps you will have no objection to hear an advocate of the other side of the question.

The institution has been removed three times since its establishment: from the Birdcage Walk to Petty France, thence to Chapel Street, and from Chapel Street to James Street. On this last occasion an advertisement appeared for a "house or premises in any part of the city or liberties of Westminster." Two suitable buildings were offered, the present hospital in James Street, and the house of Lord Lansborough at Hyde Park Corner. Dissensions, similar to those which now exist, occurred: part of the governors thought it would be advisable to remain in the same neighbourhood, while others were persuaded that by removing to a site more in the public eye, its welfare would be much promoted. The wisdom of the latter, who divided and removed to Lord Lansborough's house (now St. George's Hospital), was soon manifest, for the branch, if it may be so called, very soon surpassed its parent in wealth and utility.

We contend that the increased size of St. George's has quite superseded the necessity of a second large hospital in the same neighbourhood, for if you look at the map you will find that St. George's is surrounded by the habitations of the wealthy, and that the nearest locality inhabited by poor, is Pimlico and Tothill Fields. The Westminster Hospital has been supplied by the refuse of St. George's; the poor, when they could choose, naturally preferring the larger and more imposing institution: if this was the case when St. George's had only 200 beds, what will be the case now with 400?

It is in human nature to encourage a charity which is conspicuous and flourishing, in preference to that which is obscure and little known; the latter has been the case with the Westminster Hospital, and it is contended that if left in its present deserted situation, cut off as it now is from the wealthy classes of society by the new carriage-road through the Park, it will gradually lose those supporters who live out of old Westminster, who will naturally transfer their subscriptions to hospitals, of the existence whereof they are daily reminded. That

Westminster alone cannot support the institution even on its present scale the following facts will show:—

*Governors living in Westminster and Pimlico, including Parliament Street and all to the West:—*

18 Life governors have contributed 610*l*.

11 Honorary governors.

83 Annual governors contribute 260*l*.

*Governors living to the east and north of St. James's Park.*

83 Life governors have contributed 5450*l*.

61 Honorary governors.

141 Annual governors contribute 567*l*.

Of the building fund of 18,000*l*., 400*l*. is the whole amount contributed by inhabitants of old Westminster and Pimlico. After this statement of facts, can it be fair that the parishes of St. Margaret's and St. John's should claim as the right of their district, an institution to which they contribute so little, and which was clearly intended by its founders for the benefit of the city and *liberties* of Westminster?

It is a fatal mistake to suppose that a subscription hospital should be placed in a very needy neighbourhood. Not a poor residence is to be found within sight of St. George's: few at a less distance than a quarter of a mile, and no great number nearer than Petty France and Tothill Fields. Yet St. George's has always been better supported, and, what is of equal importance, better managed than the Westminster. Charities permanently endowed, as St. Bartholomew's for instance, may be placed in any situation, but those which depend on casual subscribers, to be flourishing, must be in sight.

After much discussion and mature deliberation at two general special boards held in June, 1828, the Duke of Northumberland in the chair, an overwhelming majority came to the resolution, "That it was advisable to remove from the present site," and a negotiation was accordingly authorised to treat with the Commissioners of Woods and Forests for ground among the contemplated improvements near St. Martin's Church. This negotiation has but lately been brought to a conclusion, and the object of the special board held on the 7th inst. was to receive the treasurer's report concerning it, when some gentlemen (43), by a *ruse de guerre*, attempted to pass a resolution refusing to receive the treasurer's report, after that gentleman has been negotiating during two years for an object which had been sanctioned at that time by a majority of 70 or 80 of the governors.

The improvements in the neighbourhood of Charing Cross afford an opportunity of obtaining a site far nearer the centre of the city and *liberties* of Westminster than the present building, and if the map of London

be consulted it will be seen how very necessary a large and efficient hospital is in that district. By establishing the new Westminster Hospital in this situation, the relative distances of the great hospitals will be more equal: the Middlesex being one mile from Charing Cross, St. George's one mile and a quarter, St. Bartholomew's one mile and a half, while the present Westminster is little more than half a mile from St. George's.

That St. George's Hospital and the Westminster are too near together is proved by this fact, that the subscriptions to the latter gradually declined as the former increased. St. George's was founded in 1734, in 1755 the annual subscriptions to the Westminster amounted to 1355*l*.,\* the average number of in-patients 120, one year (1774) there were in the house 129: from about this period the subscriptions declined, so that from 1780 to 1820 the number of in-patients never exceeded 80, and these were maintained with difficulty; the present number is 100, the annual subscription 950*l*.

In the remote and obscure part of the town where the Westminster Hospital is now placed, it is out of the reach of the more influential portion of its subscribers, its affairs have been consequently neglected, and its welfare has been, and will continue to be, if it remain in Petty France, sacrificed to local interests. I think I have shown that it was never intended as a local infirmary for St. Margaret's parish, but as a general hospital for the sick and needy, more especially those of the city and *liberties* of Westminster.

I fear I have already made my letter too long, I shall therefore endeavour to embody some of the arguments for removal under the following heads:—

1. Because the present is obscure, little known, and in a part of the town where adequate support is not to be found for a subscription hospital.

2. Because the necessity of a large hospital in the present neighbourhood is superseded by the increased size of St. George's.

3. Because an opportunity now occurs of placing it more in the centre of the city and *liberties* of Westminster, nearer to nine-tenths of its governors, in a high road where the public will be constantly reminded of its existence, and where its benefits will be extended fourfold.

It is objected that at Charing Cross there already exists an hospital. Some humane individuals have, it is true, seen the necessity of such an institution in the neighbourhood of the Strand, and so apparent is the want that their efforts have been wonderfully successful, but a period not to be contemplated must elapse before this can be

\* Considering the value of money at this time, this would be equal to a sum of nearly 3000*l*. in the present day.

come an efficient hospital, and then only by attracting the supporters of older institutions. There is some expectation that in the event of the removal of the Westminster Hospital, the governors of the Charing Cross will unite their means and energy in the support of one complete establishment. Another objection to the removal consists in the ground-rent to be paid for the new site, but arrangements will be made by which this will be paid, and a guarantee will be given to the trustees that not one shilling of the present funds shall ever be applied to this purpose.

Motives have been imputed to the friends of the removal, which are as false as they are unmerited, for they feel conscious that they are guided by such as have the real welfare of the industrious classes of the labouring community at heart; and they trust that the governors will not be biassed by the opinions of a party having a local interest in the present site of the Westminster Hospital, but aid and support a scheme which will more completely fulfil the objects of the original founders, in the establishment of a truly "public infirmary for the sick and wounded from all parts."

I remain, dear Sir,

Yours faithfully,

LIONEL J. BEALE.

Bedford Street, October 19, 1830.

LIST OF THE GOVERNOR-ADVOCATES FOR  
THE REMOVAL TO CHARING CROSS.

[From a Correspondent.]

THE following list contains the names of the more active advocates for the removal; others, though less concerned in the measure, are disposed to give it their assent. It demonstrates the large proportion of professional gentlemen concerned, and the very few governors who by residing in the neighbourhood, and possessing experience of the wants of its poor, can be aware of the deprivation which the loss of the hospital will occasion.

Those governors who reside near, and who have no other object to serve than the good of the poor, are almost to a man opposed to the removal, and feel most strongly the necessity of retaining the hospital in its present situation.

These opponents are daily becoming more numerous as the measure which has so long been kept secret becomes better known; their sense of duty to the poor of their neighbourhood, and avowed resolution to fulfil it, justify the belief that this measure can only be effected by its advocates prevailing upon non-resident governors (imperfect judges of the merits of the question) to attend and vote in its behalf.

HINTS TO THE METROPOLITAN ASSOCIATION  
OF GENERAL PRACTITIONERS.*To the Editor of THE LANCET.*

SIR,—As this Society is a nucleus, around which it *may* become desirable to form many concentric circles, I presume the members will not take amiss any observations which may suggest themselves to one not of their body. As the permanence of the Society will depend greatly upon the excellence of its laws, and the number and independence of its members, it may be worth while to inquire how far the present laws are likely to conduce to the attainment of the objects desired.

I take the liberty of thinking that the admission fee and the annual subscription exceed to an unjustifiable amount the benefit which the Society has at present in its power to bestow. Another objection to the amount is, that as the consumption of a commodity is always in proportion to its cheapness, so the serious charge for admission is a great obstacle to the rapid and extensive increase of the members of the association: a sum is demanded for the annual subscription, such as would ensure a comfortable support for the widow and orphans of a medical man, from that most excellent society for the "Relief of Widows and Orphans of Medical Men." An inevitable deduction from these propositions is, that a great accession of numerical strength would ensue, were the Society to charge less for the purchase of an abstract idea, which is really all they at *present* offer in return for one guinea admission fine, and two guineas annually.

It can scarcely be approved by thinking men, that besides demanding security from the secretary and collector, they forbear to do so from that much more responsible officer the treasurer. Nor do I believe that the appointment of a solicitor can be approved; as well might they have secretaries for the home and foreign departments; the appointment necessarily includes the payment of a salary, and in this case a salary includes a sinecure; for among attorneys there are no such things known as gratuitous services and honorary offices; they always insist on a consideration. As the Society has no occasion for a solicitor, and as the gentleman who is expected to fill this *important* office is whispered to be nearly related to one of the committee, the affair strongly savours of jobbing.

The state of the medical profession is deplorable,\* and much of the distress is

consequent on the urgent want of a radical change in medical politics. Why does not the Society immediately endeavour to accomplish it by a reasonable and spirited scheme of reform? why does it not call a convention of the general practitioners throughout England, and organise a plan for effecting this purpose? Unless the Society do this, I affirm that it is not worthy the confidence, nor deserving the support, of the general practitioners; and its present members will be little better than coffee-drinkers at a club-room, instead of medical reformers seeking to extricate themselves from a despicable tyranny and a humiliating dependence.

Yours obediently,

CRITO.

A NON-MEDICAL CORONER'S BLUNDERS AT  
PORTSEA.*To the Editor of THE LANCET.*

SIR,—Philander's cap seems to have so well fitted the head of your correspondent Veritas, that in default of disproof or defence, in the irritation of his spirit, he roundly affirms, despite all rules of courtesy, that the information I had the honour to impart to you was not "the truth." Mr. Editor, as you were lately a candidate for the coronership of Middlesex, I conceive you are very competent to judge between us, from the evidence adduced on either side.

"Sub judice lis est." It is a digressive remark, I own, "Domine Iudex," but I cannot but think them evil times when dubbed M.D.'s will spend their days in lucubrations about animal magnetism, instead of studying the laws of animal life, and stray into the shadowy paths of necromancy, when it would be more consonant to their calling to be at work at necrotomy.

It cannot have escaped your penetration, Sir, that your veracious replicant acknowledges (however inconsistent it may seem with his heavy charge of untruth against Philander), that "a discovery" was made that poor Winney was *murdered*, and did not commit suicide, as was previously sworn to by the M.D.'s, or meditators upon death, as it has been lately opined these honorary suffixes might import. Veritas most truly allows (and so did Philander), that a second inquest was directed by the Mayor, and "well and truly" observes, that "then and there," viz., at the *second* inquest, after suicide had been previously recorded, the head was found fractured, which was inadvertently overlooked before, and more extensive injury in the throat appeared than had been "at first" suspected. Veritas and Philander herein coincide, which will

\* I am told by a gentleman whose opportunities of knowing the fact, and whose veracity is unimpeachable, that a few months ago 300 medical men were receiving parochial relief in London.

doubtless astonish you, learned Sir; but will not Veritas, who is nothing but the truth, agree also as to the truth of Philander's very reasonable conclusion from the premises? viz., that such *post hoc* discoveries fix the *scandalum magnatum* on any person, of whatever degree, who, in an examination of a person who had suffered a violent death, should not, in the most cursory manner, have examined even the external part of the head, whereby an extensive fracture was overlooked, or only taken a peep, and not a survey, of the wound in the throat, which might happen to be the only injury besides. *Proh pudor!* But "murder will out, and speak with tongue of most miraculous organ," mauls the incompetent medical knowledge of coroners, or medical men to boot. Veritas must not, however, be put off his scent for truth, though that faculty should play him false in cases of murder.

"Truth shall of lies detect the auctor,  
And confound the most learned doctor."

Veritas pledges himself that the vertebrae of the neck were not partially severed, as Philander states. I have it again, and I had it before from authority, that Veritas dare not dispute that the intervertebral cartilage was cut into, and even the vertebral artery divided; and moreover an eye-witness assures me, that the head nearly fell off when not supported. What shall we say then? What can we say, Sir, but that Veritas may be very good Latin for truth, but is not truth itself. Veritas charges Philander with untruth in stating, that life must have been nearly extinguished by the blow on the head before the throat was cut, on account of the relatively small effusion of blood. As a mere matter of fact, I refer Veritas to the same authorities for their concurrence in the original statement,—and shall I say that Veritas has more dexterously evaded the point? then we will permit him to escape conviction of evading it,—which indicated that a man's hand would not be without soil of blood, who had severed his own neck. With regard to the point of physiology above alluded to, I only advise him to visit alternately the slaughter of oxen after the fashion of Jews and Christians respectively, and he will find in animals that are pithed before the throat is divided, the effusion of blood will be much less considerable than in the other mode.

It must have struck you as an instance of Veritas's regard for truth, that he acknowledges that "surgeon, coroner, and jury, were misled at the first inquest," and I am gratified that he has placed them in a proper order of sequence as it regards their causative influence. The coroner seems to have been misled by the surgeon; and as the jury

were misled by the coroner, we must ~~then~~ conclude by the logic of common sense, that both coroner and juror were misled by the surgeon, showing, what alone Philander designed to show, that a competent medical coroner would have corrected the testifying surgeon, and instructed and not misled the jury. Now, Mr. Editor, if your agreeable friend Veritas should not be satisfied, I have made certain excerpts from the first and second depositions, and shall, if need be, exhibit them in befitting contrast; and having filled up my sheet, I shall not on this occasion furnish you with any opinions of mine, whether a hard blow with a soft instrument, or a soft blow with a hard one, may have occasioned the fracture; but of this more anon. Meantime

I am respectfully yours,  
PHILANDER.

### CASES OF GONORRHOEA

TREATED BY THE TINCTURA LYTTÆ, AND  
BI-CARBONAS SODÆ.

By R. D. FORSTER, M.R.C.S.

I HAVE been led to treat several cases of gonorrhœa by the tinctura lyttæ, which was pleasingly successful, except in three instances, and in these it is evident, from the first case here detailed, that the cause of failure arose from the bicarbonate of soda having been united with the tinctura lyttæ in the prescriptions. The same case also suggested the idea that the carbonate of soda might be employed to relieve the painful, and, occasionally, dangerous symptoms produced by the cantharides; of this both cases are confirmative, the second also illustrating the striking effect frequently observed in the practice here advocated.

CASE 1.—Mr. J. B., a gentleman of robust frame, consulted me on the 24th February, in consequence of having gonorrhœa; it was the second time he had been similarly affected, and the symptoms being very mild, I should have advised the immediate use of the tinct. lyttæ, but his digestive functions were so much disordered, as not to allow the use of that remedy until the 1st of March; at this time his appetite was much improved, and anxiety (the cause of the latter affection) relieved; still from the stomach not having regained its tone, there was a continual formation of a small quantity of acid, to correct which, the soda introduced in following prescription was intended;

℞ Sodæ carbonatis, ʒiiss;  
Aquæ cinnammi, ʒiiij;  
Tincturæ lyttæ, f. ʒiiss;  
Infusio gentianæ comp. f. ʒiiij. M.  
ft. mist. cap. ʒt̄m. partem 6tis horis;

anesthetizing the patient, to discountenance its use, the moment pain in the loins, or other symptoms of strangury, were produced.

This dose of the lytta, still continuing the soda, was gradually raised, until, on the 25th March, it was 3iiss in each mixture; when ʒi to each dose was exhibited, omitting the soda, and the second occasioned alarming effects, excruciating pain, &c., which were almost immediately relieved by tinct. opii, ℥ xx; sp. camph., ℥ v; sodæ carbonatis ʒj in linseed tea; the discharge shortly after entirely disappeared.

CASE 2.—Mrs. C. W., friend of J. B., had gonorrhœa at the same time, and the symptoms being acute, two days were devoted to the antiphlogistic treatment generally necessary in the first affection; the following draughts were then advised:—

R. *Tincture lytta*, ℥ xxv;  
*Tinct. cinnam.* c. ʒj;  
*Aque menthe ptp.*, ʒj. M. ft. haustus; capiat unam ter in die.

The last (3rd) produced severe pain, but ʒj of the carbonate of soda in cinnamon water gave relief; and the discharge, which was considerable, entirely disappeared the next day.

Many similar cases have occurred; but since these two, a mixture of the following kind is invariably given to the patient, to be taken soon after the pain in the loins, &c. come on, and which always effects the object of its administration:—

R. *Sodæ carb.*, ʒij;  
*Tinct. opii*, ℥ xxx;  
*Aque cinnam.* ʒvj. M. ft. mist.

Direction.—Quarter part to be taken every hour until the pain, &c. are relieved.

Observations.—When we consider the total absence of disagreeable odour in the lytta, it having little taste and no injurious effect on the stomach, and the certainty of its action, linked with the positive power of controlling its injurious consequences by the bicarbonate of soda, I think there is not a more efficient or convenient remedy for gonorrhœa, after the reduction of the severe primary inflammation.

If requested to explain the rationale of the fact, which constitutes the only novelty in this communication, I should, with deference to better chemists than myself, suppose that the substance appropriately termed by Dr. Ure "Vesicatorium," discovered by M. Robiquet, may form an innoxious triple salt with the bicarbonate of soda; but this matter I would prefer leaving to future observation and experiment.

11, Middlesex Place, Oct. 11, 1830,

## WESTMINSTER MEDICAL SOCIETY.

October 23, 1830.

THE members of the Westminster Medical Society resumed their meetings this evening, Dr. Granville in the chair, and the Committee entertain strong hopes that the session will prove less "stale and unprofitable" than the last. The Chairman admonished the members to exert themselves, and proposed several alterations of the usual mode of conducting the proceedings, with a view to excite discussion and the relation of cases, but none of them were adopted, the members suffering the regulation of this point to be referred to the Committee. Several opinions relative to the cause of the declining interest of the Society were ventured. One gentleman ascribed it to the broken promises of those to whose care the business of the evenings was confided; another to the late attendance of the members; a third suggested that the decline was particularly owing to the want of attention which his communications had experienced, while a fourth considered that those communications were themselves the cause of the decline. No one suggested that the attendance had been thin, because there was usually nothing worth hearing, and that as the members could not be suspected to be chary of publishing their discoveries, there was little worth hearing, because little occurred to them out of the Society worth communicating, which did not appear through some other channel. In order, however, that for the future there should be no want of topics for discussion, Dr. Granville read the following list of subjects, as affording very proper matter for debate.

The political condition of the science of midwifery, and the probable advantages which have resulted from the labours of the "Obstetric Society."

The medical police of this country, and the importance of electing medical men to the office of coroner.

The existence of contagion, and the Gibraltar fever.

The characters and treatment of cholera morbus, and appearance of that disease in the south-eastern districts of Russia.

The secondary effects of colchicum.

The medical press of Europe, more especially that of Great Britain.

The advantages resulting from medical controversy,\* carried on through the medium of the press.

\* "More especially," added the speaker, "that which is at present waging between Drs. James Johnson and Wilson Philip."—Mem. Dr. Philip's last volume having been "d—d," as far as the profession is concerned, the "mysterious" portion of the title has been changed, and a name adopted which is better calculated to "carry patients along with it."

The present state of the medical profession in England.

In conclusion, the Chairman particularly recommended that the members would always address the President, speak only once, (except in explanation,) and never refer to the speakers by name.

Mr. HUNT this evening related the particulars of two cases, which want of space prevents us from giving. They did not present much of novelty.

Dr. STEWART and Mr. CHINNOCK were elected Presidents for the ensuing year.

#### THE CHOLERA MORBUS IN RUSSIA.

Our readers have probably perused in the daily papers an advertisement which has been put forth by the imperial government of Russia, offering a reward of 25,000 roubles, in *bank paper* (value eleven hundred pounds sterling), for the best treatise on "the cholera morbus," which may be forwarded to the Medical Board at St. Petersburg, before the middle of September, 1831. The advertisement, which at the request of the Russian minister in this country was put into English by Dr. Granville, states that this disease, after having of late years committed great ravages in Asia, has within the last fifteen months made its appearance in several of the Russian provinces, and intimates that the medical faculty of that empire, knowing of no "satisfactory" medical work on the subject, are unable to arrest the devastations which are committing, and which seem to threaten "the whole of Europe." Moved by "deep feelings of humanity," of which, however, it seems that deep political feelings have got the upper hand,<sup>†</sup> the imperial government requests to be furnished in the said treatises with, 1st, An account of the *nature* of the disease; 2. Of the causes which *gave rise* to it; 3. A description of its mode of propagation; 4. A demonstration, by experiments, whether it be communicable or not; 5. An indication of the measures to be taken for self-preservation, if contagious; 6. Particulars of the measures best calculated to ensure recovery.

The repeated use in the advertisement of the pronoun *it*, in speaking of the disease, instead of the noun for which that word is meant to be a substitute, renders it important that there should be some clearer understanding as to the real noun with which a connexion exists in the mind of the advertisers. "When I see many *its* in a page," says one of our soundest grammarians, "I always tremble for the writer." Our own fear is for the reader. "Little words, of

great and sweeping influence, ought to be used with the greatest care, because errors in the using of them make such great errors in point of meaning." The advertisement is headed "Cholera Morbus." Treatises are then requested on "*the cholera morbus*." The term *cholera morbus* is generic; the disease raging in Russia is particular. The first "point" on which information is required is, "the nature of the disease," signifying to common understandings the genus *cholera*. The second "point" is "the causes which gave rise to it." To what? Certainly not the cholera of any country, but the cholera which prevails in Russia. The *its* then run through all the other points but one, admitting, by a little subtlety, as readily of one interpretation as another. This one point demands the means of recovery; but recovery from the cholera of what climate? If from that of Russia, which we should suppose is intended, then to afford any chance of a successful competition for the prize, about half the value of the premium must be risked in a journey abroad, and a temporary residence in the immediate neighbourhood of the disease. At a moderate calculation, fifty candidates might be tempted to expend five hundred pounds a piece, for the hope of obtaining eleven hundred amongst them.

In the course of the evening some brief remarks, which were of considerable consequence to the subject of this prize, fell from Drs. Granville and Johnson. The facts they disclose are barely credible.

Mr. BACOT expressed some little surprise at the offer of the Russian government, because so great a body of information was already before the profession on the nature and treatment of cholera. He particularly referred to a work of 700 quarto pages, published by the government of Madras, and containing a great deal of excellent practical information on the subject, which certainly could hardly be known to the government of Russia. The volume contained a map of the progress of the disease through the country downwards.

Dr. GRANVILLE stated, that the government of Russia was not aware of the existence of this, or of any other important practical work on cholera, or a different course from the one adopted would probably have been taken.

Dr. JOHNSON said, that he had seen Dr. Leydon, or Leyton, the medical agent of Russia who was acting on the present occasion in London, and found from him that the Russian faculty were not at all acquainted with either the Madras, the Bombay, or the Bengal very voluminous reports. He gave that gentleman a list of all the works which had been published on the subject of cholera, and Dr. Leyton confessed that he had not

<sup>†</sup> From those countries to the medical faculty of which the prize has been offered, France is excluded.

seen a fourth part of them. From Dr. Leyton's description of the complaint, there appeared to be no difference between the disease which was raging in Astrakhan and that of the East Indies. Dr. Johnson thought that the Russian government would not derive one particle more of evidence from any one of the treatises which might be forwarded, than was already before the profession.

Dr. GRANVILLE observed, that the statement of Dr. Leyton, with regard to the information possessed by the Russians, might be in some measure erroneous, as Dr. Leyton had been ruralizing in Yorkshire for the last fourteen or fifteen months. He was only now about to visit Russia again if his health permitted, and could not tell but that all these works had been read there. Perhaps, however, the government would, on further consideration, retract the prospectus, and announce that the premium would not be distributed.

It is more than probable that the Russian government is totally unacquainted with the existence of the works in question, as, according to this, even their medical representative in England is ignorant of what has been published.

In consequence of the accounts which have reached London, amongst which is the following despatch from Lord Heytesbury, the British ambassador at St. Petersburg, the English government, it appears, have deemed the subject of sufficient importance to justify the immediate adoption of precautions against the introduction of the disorder into this country; communications have accordingly been addressed to the collectors and comptrollers of customs at the different sea-ports, desiring that the attention of quarantine officers may be called to the subject, in order that the standing orders may be carefully enforced.

“St. Petersburg, Sept. 15.

“My Lord,—The accounts of the progress of the cholera morbus are now becoming rather alarming. It is making rapid advances towards Moscow; it is already at Sinebiask, Tyaritzigur, Saretaff, and Pewza. At Astrakhan, the governor (Nisson), and almost every officer of police, have perished, and the other deaths are at the rate of about one hundred daily. If the disease once reaches Moscow, there can be little doubt that it will spread to St. Petersburg, Warsaw, and thence into Germany.

“This will be much less extraordinary than its regular progress from India to the Caucasus, and thence into the southern provinces of the Russian empire. It appears to be of a very deadly nature, and to

have all the character of the real Indian cholera.

“I have the honour to be, &c.,

“HEYTESBURY.

“To the Right Hon. the Earl of Aberdeen, K. T.”

*The Times* of Oct. 27, says, “We understand that accounts have been received subsequently, stating that the disorder had reached Moscow, where it was making frightful ravages. The Russian government is making all possible efforts to stop its progress.”

## LONDON MEDICAL SOCIETY.

October 25, 1830.

Mr. CALLAWAY in the Chair.

### TREATMENT OF PURPERAL FEVER.

THE subject of the last evening's discussion was revived at the present meeting, and the views of Dr. Whiting were reinforced and recombated. It will be again discussed on the evening of next Monday.

As the precise mode of treating purperal fever which Dr. Whiting would adopt, in accordance with the doctrines he had broached, was not clearly understood, the Chairman begged that gentleman to explain it.

Dr. WHITING said, that as far as preventives were concerned he could say little, and but little, he conceived, was known by any one on this point. That it was contagious he had no doubt, and he believed that if the attendant had that about his person which might be considered to be the medium of contagion, the patient might take the disease. It was not necessary to its occurrence that purperal fever should be communicated by a second party. It would undoubtedly, and sometimes did, originate *de novo*. With regard to the cure, he used to entertain prejudices against the antiphlogistic mode of treatment, and at one time avoided it; but he now conceived, as the result of very decided experiment, that that was the only mode which, in the majority of cases, could be successfully employed. He said the majority, because he believed that there really were some few cases in which depletion was not absolutely necessary, for the disease would, in fact, pass away spontaneously; it would run its course, and ultimately disappear of its own accord. The truth was, that under any treatment it could not be stopped. Antiphlogistic means would tend to facilitate this, but no treatment would, of itself, perform a cure. There was this distinction between common inflammation and purperal fever, or erysipelas of internal membranes (the same being equally true of erysipelas of the skin), that the

former could be decidedly stopped by antiphlogistic measures,—by measures which would put down and keep down the heart's action, while the latter could be subdued by no such means. A patient with erysipelas of the skin might be bled to syncope, without stopping its progress; the erysipelas would still spread. All that could be done in this, and all that could be done in puerperal fever, the danger of which was much increased by its being an internal erysipelas, was to *mitigate* the inflammation. It *would* run its course, but the mitigation by antiphlogistic means assisted the inflammation to stop before it arrived at such a height as to destroy life. Such being the fact, it was important for them to observe on what principle those means should be conducted. This principle was not that of reducing the patient on the instant. If the position was correct, that the inflammatory process, the erysipelatous attack, could not be *stopped*; but would only yield of its own accord, depletion could do no further good than to mitigate its severity; it might reduce the energy of the system, by the aid of which the disease might ultimately subside. The careful and judicious employment, then, of antiphlogistic measures, was the desirable course, and amongst those, bloodletting would be found to be the most important. Now he was convinced, that if gentlemen did nothing more even than read those authors who had written on the subject, they could come to no other conclusion than that the antiphlogistic, and not the opposite, was the proper plan; but if they did this, and also saw cases of true puerperal fever, they could not possibly fail to become disciples. In connexion with bloodletting, the treatment he adopted was the administration of the tartrate of antimony and calomel. Of the antimony, his practice was, to give just enough to preserve a constant slight sickness at the stomach; the quantity, therefore, was regulated by its effects. He began, perhaps, with half a grain, and followed this up with another half or a quarter of a grain, as the purpose seemed to require. The calomel he commenced with three grains, in conjunction with opium, to allay the irritability of the system, and kept up the dose to the production and sustaining of a soreness of the gums. By this treatment he had cured two as decided cases of malignant puerperal fever (those referred to on the last evening) as he ever saw. The great fault with practitioners was, that they had generally bled too indiscriminately in the latter stages, when that course was tried, and destroyed the power which was necessary to sustain life until the inflammation stopped.

Mr. CALLAWAY here observed, that he did not exactly see in what this treatment

differed from that employed in *common peritonitis*.

Dr. WHITING replied that the difference was essential. In common peritonitis it was usual to bleed and prescribe the tart.emet. in large quantities, with a view to stop the inflammation at once; but it was to be borne in mind that this disease would proceed, in spite of remedial agents; the antiphlogistic means, therefore, should be so managed, that the energies of the system might be preserved, eventually to work out the cure.

On the whole, the members were not satisfied with this plan of treatment, but their objections were confined to the simple expression of dissent, and need not, therefore, be detailed. One or two references also were made by Dr. Whiting to authors in support of his views, the justice of which being questioned, we refrain from quoting them, as their apposition to the question required to be further shown.

\* \* In our last report, Dr. Whiting is stated to have attended a patient, to whom he referred, in *child-bed*. Dr. Whiting does not practice midwifery, and the statement, therefore, was erroneous. Mr. Olding was the accoucheur.

---

#### SOCIETY OF GENERAL PRACTITIONERS.

##### *To the Editor of THE LANCET.*

SIR,—In a letter addressed “to the General Practitioners of the United Kingdom,” through the medium of *THE LANCET*, on the 9th instant, the writer submits sundry queries respecting the Metropolitan Society of General Practitioners, to which you were pleased to subjoin an appeal that places the explanation to *my* account. If I have been wanting in promptness to your correspondent, or been deficient in respect for your assurance of my ready courtesy to him, by delaying to reply, I request it may be attributed to a sense of my duty to the *Committee*, before whom I considered it incumbent on me to bring the subject. And now, not having obtained authority from the Committee to answer the questions propounded, I can only reply, that as an individual merely of that body, I dare not undertake to interpret its intentions unadvisedly.

I have the honour to be, Sir,

Your obedient servant,

JAMES SCOTT.

Regent Street, Oct. 26.

## THE LANCET.

*London, Saturday, Oct. 30, 1830.*

ALARMED at the portentous aspect and convulsive changes of the times, the FELLOWS of the College of Physicians already exhibit tokens which indicate pretty clearly that the downfall of their dynasty is fast approaching. Bullies and cowards, who deem themselves in danger, may ever be recognised by their often-repeated and boisterous threats directed against their pursuers. Destitute of real, solid power, they have recourse to artifice for protection. They elevate their empty heads, move pompously, raise the arm minaciously, and assume the stern countenance of confidence and integrity. Thus it is with the College of Physicians. Existing in a piece of old mildewed parchment, and not in the hearts of the profession, possessing the paraphernalia of titles, dignities, and power, and yet holding no place in the confidence or estimation of the great mass of the best-informed members of the community, their threats are about as wise as the antics of the fool who shook his bells in order to attract the attention of the bystanders. Experience seems to be entirely useless to the individuals who hold the reins of government in this body. Their perceptive faculties appear to be directed backwards, and their learned researches to reach no further than the year 1300. In the aggregate, always inferior in talent to the great body of practising physicians in this country, and lamentably destitute of opportunities for exhibiting the little skill they have possessed, nothing short of infatuation, or the most blind conceit, could have stimulated the "fellows" to maintain a monopoly, virtually injurious to the private interests, and nominally and really obnoxious to the feelings, of the rest of their professional brethren. In the estimation of these extraordinary gentlemen, the numberless mi-

series which follow in the train of poverty, are nothing in comparison with the pleasures derivable from an *exclusive* title. They discover in the characters—"Fellow of the London College of Physicians," ample recompense for empty coffers, unfurnished larders, and diaphanous decanters. They appear as though they lived, moved, and had their being, by *title*. The universities in which they study, have neither hospitals nor dissecting-rooms—are destitute of the materials for acquiring even the elements of medical science; but no matter; their medical accomplishments are vastly superior to those of all other physicians in the universe; and as for the surgeon in general practice, they cannot even think of his pursuits at less than a falcon height. The smell of rhubarb is fatal to them; the bare sight of a pestle and mortar would produce the horrors, and drive them stark staring mad. Their conceit is unique, and, like Narcissus, the only pursuit (an extraordinary one, certainly, for such high-minded souls) which appears to yield them any enjoyment, is that of viewing their own "exclusive" beauties and perfections.

"Pride hath no other glass  
To show itself, but *pride*; for supple knees  
Feed arrogance, and are the proud man's rage."

So says Shakspeare; and the College, in the person of their President, have split this axiom into two. In short, they are liberal in commerce, if not in science; and Sir Henry Hallford, pushing the reciprocity system to the extreme; unwearied and indefatigable in proffering the great man's compliment, the genuflexion fee, he has received, in the way of barter, an immense weight of a metal, which, could it be more generally procured, would be very frequently employed by practitioners in medicine. A flexible knee, a supple back, and a courtier's head, have enabled Sir Henry Hallford to carry on a thriving trade, and to "boo" his pretensions into the Palace, and into almost every nobleman's mansion in the kingdom. His influence in the Palace is

not inferior to his power in the College; president at Pall-mall East, and royal "bulletin" signer and medical caterer at Windsor, he obtained from his present Majesty, and filled up without opposition or remonstrance from his spiritless colleagues, a *carte blanche* for the "ordinary" and "extraordinary" personages who were to constitute the royal medical staff. The list made up by his selection on that occasion, we shall one day employ as a key to unlock, and lay open to public view, a few of the peculiar springs which have usually regulated Sir Henry's public conduct. Thus much we may now say, that the physicians of England are not his debtors. If the wheel of fortune turn but to benefit the *president* of the College, how fares it with the *fellows*? Sadly indeed; unless universal neglect and contempt are equivalent to public respect and confidence. If these gentlemen could but estimate their self-importance somewhat less erroneously, there might be hope of reformation; but, half blinded by conceit, they are unable, even transiently, to discern what is constantly obvious to every other member of the profession, namely, their present powerless, miserable, ludicrous, position as a chartered corporation. What are the privileges of which they can boast? That of demanding by virtue of their "charter," that no physician, if he be not a graduate of Oxford or Cambridge, shall practise in London, without one of their licenses. Hence they every now and then resort to the fool's play of citing their superiors to an examination; an examination incapable of conferring dignity, and insufficient for the detection of incompetency. They arrogate to themselves the exclusive management of the funds and general affairs of the College, and limit the elective franchise to their own keeping. We had well nigh forgotten another privilege, and the by-law which concedes it is entirely, exclusively of their own manufacture. It is, that every "fellow" of the College who shall meet

in consultation any physician who may not be recognised by the charter and by-laws of the College, shall forfeit, for each offence, five pounds. This by-law applies, amongst others, to the graduates of the University of Edinburgh. Now it is pretty well known that we have no very great partiality for the Scotch Colleges, but it would be disgraceful for us to withhold the fact, that those who became "fellows" of the London College of Physicians, until within a very short period, were indebted to the medical schools of Edinburgh for whatever knowledge they possessed of medical science.

Are the privileges, which we have just enumerated, consonant with the claims and dignities of a learned and liberal body? The bare mention of a *national college*, we understand, has set the whole corporation in commotion; and vengeance, with renewed fury, is threatened against the contumacious "independent" physicians; that is, against those graduates of Edinburgh and other universities, who, in defiance of the charter and the by-laws, practise in London without a license obtained from the College in Pall Mall East. It would afford us sincere pleasure to see this respectable College step once more into the arena of a court of law to enforce the penalties against the *non permisi*. Discussion, we apprehend, has no agreeable sounds for them, and it were now far too hazardous a measure to commit to Newgate for "contempt." Public feeling is rather different to what it was in 1703; but even then, the poor College fairly got its right arm broken, while outstretched in its effort to grasp after the foul fruits of monopoly. It is right that the profession should know, it is right that the *independent* physicians should know, it is right that the surgeons and apothecaries should know, that the College of Physicians, in the year 1703, prosecuted an apothecary for visiting and prescribing for a patient, and actually obtained a *verdict* for the penalties; but the apothecary, the spirited, the undaunted apo-

thetary, Mr. Rose, to whose memory a monument ought now to be erected, tried the question in parliament upon a writ of error, and obtained a splendid victory, as the judgment in the court of law was completely set aside. The College in this instance, by indulging their spirit of monopoly to the very letter of the law in that vile statute which they still hold, lost for ever all power over English apothecaries and their concerns, with the single exception of being still empowered to enter their houses and examine their medical preparations, a right "more honoured in the breach than the observance." Had it not been for the noble and spirited resistance of Mr. Rose to the unprincipled and grasping tyranny of the College, there might not have been in the British dominions, even at the present hour, a single *dispensing* surgeon.

The author of "The Laws relating to the Medical Profession," observes in his preface, that he could not "dismiss his pages without acknowledging his obligation, for much valuable information, to Dr. Macmichael, lately the registrar of the College of Physicians." It certainly affords us pleasure to find that Mr. Willcock was successful in such a quarter in his search after knowledge, for if the various published writings attributed to Dr. Macmichael really came from his pen, he is the last person to whom we should have applied for information on the subject of medical legislation. Dr. Macmichael, at all events we believe, could not look upon any laws that were favourable to surgeons or apothecaries, otherwise than through an obnoxious medium. He was an appropriate registrar for the royal "bulletin" signer, and appears to have macerated all his life in a *tinctura aristocratica*. To some such genius, Mr. Willcock, we suppose, is indebted for the following piece of information:—"The practice of the physician is universally understood, as well by their college as by the public, to be properly confined to the pre-

scribing of medicines to be compounded by the apothecaries, and in so far superintending the proceedings of the surgeon as to aid his operations by prescribing what is necessary to the general health of the patient, and for the purpose of counteracting any internal disease." Insolence! Why the practice of physicians of the present day, consists in lamenting that they have no disease for which to prescribe. Although physicians, merely because they practise as pure physicians, are now confessedly without patients, they still insist upon their exclusive right to prescribe remedies for internal diseases, and even for the general health, when that is affected by the progress of external disease. They vsunt not quite so much as formerly of their superior medical education, as the fallacy of that pretension has been completely and usefully exposed in the pages of this Journal. They have changed their ground; it has become fashionable with them to reprobate the "unnecessarily" high charges made by surgeons for operations, and the "unnecessarily" large quantities of medicines sent in by apothecaries. Thus the practice of the physician is represented as being more pure, more gentlemanly, more honourable, than that of surgeons or of apothecaries. Indeed, the system of the apothecary is denounced as one of cupidity and imposture, as one founded in deception and fraud, leading, in fact, to direct plunder. Check the strong current of your virtuous indignation for one moment, worthy doctors! Pause awhile, gentle and amiable physicians! We must ask you a question. Was it never suggested to your sagacious minds that a physician can pay an "unnecessary" visit, write an "unnecessary" prescription, such as "rep. med.," or extract an "unnecessary" fee from the pocket of his deluded patient? Oh dear! "How infamous in THE LANCET to allude to such things!" Not at all. The "unprincipled and plundering practices of apothecaries" have long since been loudly bruited abroad by physi-

cians, and why should not apothecaries promulgate the truth concerning their calumniators? Physicians are *not* upon principle, probably, very strongly opposed to the "plundering" system, and their hostility, such as it is, arises only from a dread lest they should not have all the booty to themselves. They bitterly reproach an apothecary who can presume to make his patient pay one shilling and six-pence for an "unnecessary" draught, because, being an undignified character, the misdeed is enormous; but a physician who takes one dozen or one hundred "unnecessary" fees is guilty of no immorality at all. The venality of the deed is shielded by the high reputation and collegiate title of the misdoer. The web of the law is only strong enough for small flies, and "great men have but little sins." The title of *doctor* is now the last hold which physicians have upon the public mind; and upon that ground it is hoped that all qualified English practitioners will soon meet upon equal terms. There exists no desire to *bring down* the "doctor," but it is high time that the "general practitioner," by taking *his* proper title, should be elevated to that rank which his talents and utility so pre-eminently entitle him to maintain. That many of the fellows and licentiates of the College are men of splendid professional and literary attainments, we will not deny; but as a *body* of practitioners, they must in medical acquirements be content to rank far below the majority of dispensing surgeons. Is this College of Physicians then entitled to the support or confidence of the profession? If not, let us unite all our energies in raising a NATIONAL COLLEGE OF MEDICINE, which shall command respect and admiration throughout the scientific world.

Many correspondents express great anxiety for the development of the scheme of the intended College, but we think it will be a more prudent course to withhold it,

until the merits and defects of the existing corporations shall have been fully discussed. We may state, however, *en passant*, that the plan is exceedingly simple, and founded entirely upon two great principles—EQUALITY OF TITLE, and EQUALITY OF RIGHT.

---

In another part of this Journal will be found a report of an inquest held last week on the body of a Mr. Kinnear. Of the deficiencies of non-medical coroners it is now unnecessary to speak, and we do not allude to the proceedings even for the purpose of reprobating the unjustifiable and senseless hesitation of the coroner in directing the examination of the body. But we wish for one moment to call the attention of the profession to the report of the medical gentlemen who attended the *post-mortem* inspection, and if the examination were conducted as slovenly and carelessly, as the report is written loosely and inaccurately, it might as well have been avoided altogether. Death, we are told, was produced by "the rupture of a blood-vessel *on* the stomach," and that some thirteen or fourteen ounces of the blood that had escaped, were found in the right and left cavities of the thorax. Now, assuming that "*on*" is (indeed it *must* be) a misprint for *in*, we cry mercy! and ask, in what manner blood, poured into the stomach, made its way into the bags of the pleuræ. In requiring from Dr. Patterson and the other gentlemen an answer to this question, we take this opportunity of thanking the Doctor for the earnestness and pertinacity with which he insisted upon the necessity of examining the body.

---

We readily insert the letter of Mr. Morrison in generous vindication of his friend, Mr. Bowen, but the writer should have borne in mind that, whatever animosity might have existed in the minds of rivals, it was *not malignity* that forcibly tore off

the arms of the fetus. The practice of Mr. Bowen in the case in question was utterly indefensible, and the correspondence on the subject had better terminate. We should like, however, to be furnished with the names of the three "lecturers on midwifery," who are said to have approved of the treatment of Mr. Bowen. Their names ought to be inscribed in conspicuous characters over every mantlepiece in the country.

---

WESTMINSTER HOSPITAL.

At a general meeting of the governors on Wednesday last, it was decided by a majority of sixty-two to twenty-seven, that the building should not be erected at Charing Cross. A ballot was demanded. The longer we contemplate the scheme for the "removal," the more does it assume the appearance of a job.

---

*A Treatise on the Mineral Waters of Harkogate and its Vicinity.* By ADAM HUNTER, M.D., &c. London: Longman, 1830. pp. 138.

FURTHER than the analysis of the springs is concerned, the medical profession can attach but little importance to any treatise of this description; there is, however, a vast number of curious invalids, and amateurs in therapeutics, who thirst earnestly for every information on the subject. To gratify, to a certain extent, the appetite of this interesting class of persons, we present them with a summary notice of the present publication.

As Dr. Hunter has afforded us a new and elaborate analysis of the "old sulphur" well, and of some other springs of more questionable efficacy, we shall select his results in the most remarkable instance. We shall also quote his mode of analysis of the gases contained in the former, as a fair specimen of his ingenuity and adroitness in chemical manipulation. It is true that he cannot lay claim to novelty in design, and that his execution is not totally free from error; still, as an example of the practical

application of analytic science, we think his investigation deserves considerable praise.

"To separate the gaseous contents of the water, four pints were boiled in a glass retort with slips of platina, until the quantity of gas received ceased to increase.

"It was received in a narrow vessel, over a small portion of water, in preference to mercury, on account of the action of sulphuretted hydrogen on that metal.

"It measured seventeen cubic inches, at the temperature of 60°, equal to thirty-four inches per gallon. A tube, graduated into hundredths of a cubic inch, was filled with and transferred to a bottle containing carbonate of lead, diffused in a small quantity of water; on agitation an absorption took place, amounting to 46 of a cubic inch, or 15.64 inches, from the gases contained in a gallon.

"The residual gas was treated in the same manner with liquid potash; the absorption was 8 per cent. of the gas originally operated on, or 2.73 cubic inches from the gases in a gallon.

"The method of gaseous analysis by absorption, is decidedly superior to the formation of precipitates; some sources of error are common to both; but the quantity of precipitate from the gas yielded by a moderate quantity of water is so minute, that very small errors, during the several processes of formation, collection, washing, drying, and weighing, have a material influence on the quantity of gas denoted by the final result. A loss or increase of one-hundredth of a grain on the carbonate of lime, produced in operating on a pint and half of water, would give rise to an error of one cubic inch in the calculation for a gallon. The eudiometrical method, which was pursued, is short, easy, and susceptible of great precision; an error in the carbonic acid of two whole divisions of the tube, would scarcely affect by half a cubic inch the quantity in a gallon.

"The proportion of gas, 46 per cent., which was not absorbed by carbonate of lead or by potash, was mixed with twice its bulk of oxygen, and exploded by the electric spark. On agitation with potash after the explosion, 60 measures were absorbed; one-third of this diminution was carburetted hydrogen gas; viz. 20 per cent., or 6.8 cubic inches per gallon. The residual gas, 26 per cent., was added to a mixture of oxygen gas, with more than twice its bulk of hydrogen; the diminution after explosion was exactly three times the oxygen introduced, showing the total absence of oxygen in the gases from the water. This portion of gas 26 per cent., or 8.84 cubic inches per gallon, may be considered as azote."

We do not think it necessary to notice his

method of analysing the fluid itself. The results are as follows :—

“By calculation from these data, the water of the Old Well is found to contain, in an imperial gallon :—

Sulphuretted hydrogen	15.64 cubic inches.
Carbonic acid.....	2.72
Carburetted hydrogen	6.8
Azote .....	8.84

Which are given out in the gaseous form on boiling.

Remaining in the water :—

Chloride of sodium.....	867.2 grains.
Chloride of calcium.....	87.2
Chloride of magnesium ..	42.4
Bicarbonate of soda.....	20.”

The gaseous analysis contains one remarkable error, by which the quantity of carbonic acid must be estimated at too high a rate. Dr. Hunter does not seem to have remembered that carbonate of lead evolves carbonic acid when agitated with sulphuretted hydrogen. In fact, not a particle of this gas can be absorbed without a corresponding evolution of carbonic acid from the carbonate of lead. The extent of the mis-statement, which must have been the result of oversight, may, therefore, be readily perceived.

His views respecting the origin of the sulphuretted hydrogen, are, to a certain extent, original, and, we believe, correct. It is a subject which has puzzled many experimentalists, but Dr. Hunter certainly contributes much to its elucidation.

“In reflecting upon this subject, in connexion with the analysis, I am almost convinced that the sulphuretted springs acquire their impregnation in passing through the thick stratum of shale already mentioned. It has been satisfactorily proved by experiment, that sulphate of soda, dissolved in water, is decomposed under some circumstances by vegetable matter; the water yields oxygen to the carbon of vegetables, forming carbonic acid, part of which, with the soda formerly in the state of sulphate, constitutes carbonate of soda, and the remainder is found in the state of gas. The hydrogen of the same portion of water, and the sulphur from the sulphuric acid, form sulphuretted hydrogen. If we suppose that the carbon of carbonaceous shale performs the same office, it will account for the production of the sulphuretted hydrogen, and the carbonic acid gases. And it deserves to be mentioned, in corroboration of this view, that those springs at Harrogate which yield most sulphuretted hydrogen, contain

no sulphates, while in those in which, from the absence of that gas, such a process has evidently *not* taken place, the sulphates abound.”

Dr. Hunter's object throughout the treatise, is evidently rather to render it a safe popular companion, than an efficient substitute for medical attendance: he fills his pages with the romance, and the history, rather than the science, of water medicine; and having seasoned his details with lively local descriptions and chemical episodes, he has produced a little book aptly calculated to increase his district reputation, and even, in some particular points, to extend his general celebrity. As far as Harrogate is concerned, we earnestly trust that this volume will effectually supplant the numerous and deadly manuals of empiricism which infest the hypochondriac's library. Dr. Hunter has advanced nothing which can injure, but much that may materially benefit, the non-professional peruser. More than this it is unnecessary to advance in his commendation.

---

*A Demonstration of the Nerves of the Human Body.* By JOSEPH SWAN. London: Longman and Co. 1830. Eleph. folio. Four Plates. Part I.

MANY of our readers are probably aware, that Mr. Swan has bestowed much time and attention upon the anatomy of the nerves, and that the Collegial prizes for 1825, and 1828, were adjudged to his dissected preparations. The present work is intended to consist chiefly of engravings taken from those preparations, and the part before us contains the ganglia and ramifications of the sympathetic, in the head, neck, and thorax.

The author commences with a few observations on the sympathetic nerve, which afford little or no information that may not be found in most anatomical works, with the exception of the following statements, which we cannot pass over without comment. After describing “the ganglia of a healthy subject” as “firm, nearly *white*, or *pearly*, and without blood-vessels,” and as having a somewhat pulpy appearance when divided, &c., he observes,

“After a minute examination, a ganglion appears in the following manner; for in-

stance, the termination of the splanchnic nerve divides into an infinity of ramifications, which become entirely blended in the substance of the semilunar ganglion, the nerves afterwards arising from the ganglion are seen first in its substance, as very minute white streaks, and these collecting into threads, join together to form branches to be distributed to the viscera. The structure of the other ganglia of the sympathetic, appears nearly the same as that of the semilunar; the branches proceeding from these begin in a similar manner, and on approaching the spinal nerves, separate into minute threads, and become incorporated with their fibrils."

Now, in the first place, the ganglia of the sympathetic, according to our own observation, and the statements of all the anatomical writers with which we are acquainted, are not of a white or pearly, but a reddish-brown, or reddish-grey colour, and they are not generally considered as firm, but soft: in the second place, the semilunar ganglion or ganglia, being formed in a somewhat different manner from the other ganglia, often bearing more resemblance to a plexus, ought not to have been chosen as a specimen of the whole; and, thirdly, the structure described, though more perceptible, perhaps, in the ganglion in question than in the rest, is not universally admitted, and cannot at all events be demonstrated without great difficulty, whereas the author has stated it as a plain, undisputed, fact, and as though it were cognizable by any ordinary observer.

The commencement of the sympathetic nerve he considers to be from the superior cervical ganglion, and not from the sixth cerebral nerve, since, in some animals, the communication with the latter is very small, and, in others does not exist; the ascending filaments communicating chiefly with the gasserian ganglion, with respect to which he observes,

"On immersing the first cervical ganglion of the sympathetic of a sheep, and the gasserian ganglion with a portion of its nerves in a solution of potassa, the cervical ganglion and its branches became quite transparent, and proceeded with the same appearance to their connexion with the gasserian ganglion; this was white, and therefore had the branches proceeded from it to the first cervical ganglion of the sympathetic, these would have been white also. It may, therefore, be fairly concluded, that these were passing from the sympathetic to the gasserian ganglion."

Without pretending to decide the point, we will only observe, that this experiment does not appear to us to be by any means conclusive. In order to make it so, it must be shown that the minute branches of the fifth pair are not liable to be acted on by the alkaline solution, which we imagine it would be rather difficult to do.

On the rest of Mr. Swan's work, it is unnecessary for us to offer any observations, as it consists of little more than a mere description of the plates. We therefore pass on to the latter, which, we regret to state, are not such as might have been expected from the splendour, size, and price of the work. The engraving, though not first-rate, is hardly to be complained of, since, as far as the engraver was concerned, every thing is well and clearly shown; the fault lies with the draughtsman, who having probably no knowledge of anatomy, has committed several errors so conspicuous, that we wonder they were not at once observed and corrected by the author. These errors occur chiefly in the first plate, to which we shall confine our remarks. Here the sphenopalatine ganglion, instead of being distinct from the superior maxillary nerve, or second branch of the fifth pair, and connected with it by two or more short filaments, is represented as a short stem or trunk branching out from it without any intervening space whatever. The hypoglossal nerve is represented as a branch of the pneumogastric, given off more than an inch below the mastoid process, the latter nerve appearing before, as well as after this division, as a single round chord. This is surely wrong, for although the two nerves are for some distance closely united, and contained in a sheath of dense cellular tissue, they do not appear exactly as a single nerve, and ought, at all events, not to have been shown as such in the present instance, where the dissection has been carried to a great extent, and where the ascending filaments of the superior cervical ganglion, which are contained in the same sheath, are distinctly seen. The same nerve is also represented as gradually increasing in size after it has crossed the external carotid, so that where it passes behind the submaxillary gland, it is more than twice as large as where it has just given off the ramus descendens. The facial or external maxillary artery is repre-

sented as large as the trunk of the external carotid, after the origin of the occipital, though even this is rather too large. The root of the third branch of the nervus trigeminus, appears nearly as large as the sciatic nerve, and some of the other nerves and vessels, as well as all the ganglia, are certainly larger, in proportion to the other parts, than we have ever observed them. With the exception of these errors, and a few others of the same kind, but of less importance, the plates are very clear and accurate, and are far superior to any others on the subject, with the exception of Walter's, which, however, do not include the nerves of the head, neck, or upper part of the thorax.

---

*The Anatomy of the Human Body, illustrated by 158 Plates, taken partly from the most celebrated Authors, partly from Nature.* By ANDREW FYFE, F.R.C.S.E. Black, Edinburgh; and Longman and Co., London. 1830. Description 8vo. pp. 233. Plates 4to.

Of the present edition of this miserable performance, which is still worse than the original one, and appears to be a mere trading job, we can hardly speak in terms of sufficient reprobation. Not only are the drawings and engravings of the lowest grade of art, but the plates are full of the most absurd blunders and misrepresentations, so that it is impossible to guess at the meaning of some of them, and others might rather be considered as *fancy sketches*, than as copies from nature. Where the whole is so utterly bad, it would be useless to waste our time and space in pointing out particular faults; we shall only, therefore, observe, in conclusion, that there is scarcely a plate which would be more instructive to the student than a tolerable description, and there are many which would either completely puzzle him, or lead him into the grossest errors.

---

#### MEDICAL PROMOTIONS IN THE ARMY.

*To the Editor of THE LANCET.*

SIR,—Considering the very great and well-merited influence, which your valuable Journal has acquired with the public, I am

always sorry when any statements, savouring more of personal feeling than public good, are admitted into its pages. Of this nature I consider a letter in your last Number from some discontented medical officer, and perhaps one too (were his merits inquired into) little deserving of favour or promotion. Sir James M'Grigor may have his partialities and favourites in the department, and who, in his situation, at the head of a large public department, would not? "But let the devil have his due." Sir James M'Grigor had no more to do with the promotion of the gentleman whose name is so improperly introduced by your correspondent than you had; and as the circumstances connected with that promotion are so highly honourable to all concerned, I think they ought to be generally known.

Mr. Jemmett is a gentleman of the highest literary and professional attainments, of the most amiable and accomplished manners, and of the highest character. He is the only son of a gentleman who has spent *more than thirty years* in the King's service, and immediately about the person of his Majesty, with a devotedness and assiduity that have seldom been equalled, and which I am sure are duly appreciated where they ought to be. Mr. Jemmett, after completing his medical education, entered the army, nearly six years ago, as an hospital mate, and was afterwards removed to the 12th dragoons as an assistant-surgeon. *He had served fully the time specified by the regulations*; and, Sir, was it not natural, *aye and reasonable*, that he should try to get promotion as soon as he was eligible? and does it not say much for the kind affection and goodness of heart, the generous and noble conduct of the EXALTED MASTER, that could gladden the heart of a faithful servant, by what he knew would give the greatest joy to him as a parent, while, at the same time, it was rewarding *merit seldom to be met with*? In fact, Sir, his Majesty's commands were conveyed to Sir James M'Grigor, and in a manner that left him only obedience; and all who know Mr. Jemmett will agree with me in thinking the service is honoured by his promotion. Your correspondent ought to know that the length of time a man may have been permitted to receive his Majesty's pay, often affords but a very negative claim to further promotion, and I defy the very worst enemies of Sir James M'Grigor to accuse him of having kept back any officer of distinguished merit, when it was possible to get him provided for, even without the aid of any patron; I think I could mention one or two instances in which he has resisted the solicitations of a PRINCE REGENT; and many, where he has opposed even the recommendation of the commander-in-chief (the

second person in the empire) with effect, when the persons so recommended were unworthy; therefore let us be just in our censure. I owe Sir James no favour, but rather the contrary; and am only actuated by a love of justice in troubling you with these observations.

I am, Sir,  
Your sincere admirer,

FAIR PLAY.

London, Oct. 25, 1830.

SINGULAR RESULT FROM THE EXTERNAL  
USE OF CORROSIVE SUBLIMATE.

To the Editor of THE LANCET.

SIR,—With the following extraordinary statement you have my name and address, that there may be no doubt as to the correctness of the facts related in it.

A gentleman, ætat. circ. 26, applied to me eighteen months since, to furnish him with some remedy for certain disagreeable animals. I directed him to procure a little *white precipitate*, to rub it up with spermaceti ointment, and to apply the mixture to the infested neighbourhood. He followed the directions, and became rid of the nuisance. About a fortnight since, however, he discovered that a second invasion had taken place, but, on this occasion, forgetting the words of the prescription, he obtained a small packet of *corrosive sublimate*. Five grains of this he reduced to powder, united with some oleaginous substance, salt butter, I believe, and rubbed the mass briskly in over the whole of the lower part of the abdomen, the penis (sparing the glans), the scrotum, and the perineum. He very soon, as may be supposed, suffered the tortures of the damned, and language was hardly adequate to describe the agony that he endured during the night, which was then approaching. Being in no situation to attempt relief, nothing was done for one or two hours, and then for a long period a boy was employed, alternately with cold water and flour, to assuage his sufferings. By the morning the pain had greatly lessened, and shortly after, a tingling sensation only remained. The entire cuticle of the scrotum desquamated, having first risen all over in small blisters, each about the size of a grain of wheat, and filled with a pale yellow, barely fluid, pus. The torment was most severe in the testes; these appeared to be consuming by exposure to fierce flame.

The singular result follows. No further symptom ensued, and the circumstance might have been forgotten, but seven days after the mistake, upon trying to polish the ring on his hand with one of his fingers, he was astonished at discovering an appearance

of mercury on the gold, and proceeding to burnish the metal all over, he readily covered the entire surface with a plating of quicksilver. The circumstance was immediately made known to a medical gentleman present, and the discs of three sovereigns were also mercurialized. The following morning I chanced to see the party, and by rubbing the handle of a gold eyeglass upon the inner surface of the arm, obtained a similar result. A portion of the milled edge of a sovereign was also thus so completely coated with mercury by me, that no glimpse of the gold could be seen through it. I immediately made the strictest examination into the state of the mouth, but not the slightest pyalism, enlargement, unusual redness, or looseness of the teeth, was discoverable, or had for a moment been experienced! The health was as usual. There had been no exposure to cold air. The diet had been moderate, with large quantities of warm diluent fluid. The general personal appearance was precisely what it had been for a long time. My experiment was made on Thursday the 21st instant. I simply place these facts on record, and remain,

Sir, most faithfully yours,

M.

London, Oct. 25th, 1830.

NOTE FROM MR. KING.

To the Editor of THE LANCET.

SIR,—Mr. Earle having mentioned to me, that the report of one of my speeches made on the hustings in reply to Mr. Baker at the late election for coroner, contains expressions which he considers injurious to the character of the hospital surgeons, I lose no time in explaining that I did not intend to cast any imputation upon their private conduct. My observations were directed against the system of electing medical and surgical officers to our hospitals, which I consider unjust, and which, as far as my experience goes, they patronise. I shall feel obliged by the immediate insertion of this communication, and have the honour to remain,

Your obedient servant,

T. KING.

10, Hanover Street, Hanover Square,  
Thursday October 28th.

QUACKERY.

To the Editor of THE LANCET.

SIR,—You must not believe that the success of quackery in the practice of physic is

limited to the atmosphere of the metropolis, or even to that of England; it is most successful even here, but not altogether without the aid of the law of primogeniture, as the ladies of rank and fortune in this neighbourhood are, it is said, the only females who have "justly appreciated and handsomely rewarded the extraordinary powers" of the Lahinch professor. Pray insert, with all its typographical embellishments, the following delicate *morceau*, upon which credulity in the upper ranks has long fed most luxuriously, and happily most *loisingly*.

Yours faithfully,

CHIT.

"To the Ladies of LAHINCH, &c.

"THE celebrated Mr. EDWARD O'CONNELL DUNNE begs leave to inform the Ladies of Lahinch, and its vicinity, from the age of *FIFTEEN* to *SEVENTY*, that he has in his possession an agreeable preparation which has been found upon trial most efficacious in cases of barrenness, &c. &c., to cause the immediate procreation of children!!!

"The present is an advantage which does not frequently occur, it is therefore requested that a speedy application be made, as Professor DUNNE is about setting off for Bath and Cheltenham, where his extraordinary powers have been duly appreciated and handsomely rewarded.

"N.B. This *fructifying preparation* may be had of Professor DUNNE, by a *private* and *personal* application at his Lodgings."

#### DESCRIPTION OF A LIVING QUADRUPED CHILD.

At the sitting of the Académie des Sciences, on the 6th of September, a child with four feet was presented by Madame Heu, midwife, who had been present at its birth. The following is an extract from the report of M. Geoffroy St. Hilaire on this curious phenomenon:—

The child is of the male sex, and was born at Paris on the 4th of July last; both parents are well formed, and have several children, none of whom are deformed in any way. The mother being rather of lively temperament, has frequently exerted herself greatly in her usual occupations, but does not recollect that this had been particularly the case during her last pregnancy, which was regular, except that from the beginning to the fifth month, she was subject to a slight discharge of mucus and blood. The child was born in due time after a natural

labour. Its monstrosity consists in the lower extremities being double; the pelvis is regularly formed, but there is evidently a tendency towards the formation of a double pelvis, there being between the coccyx and the left half of the pelvis an osseous rudiment by which the sacral bone and the coccyx is pushed towards the right, and which may be considered to represent the additional iliac and ischiatic bones in an atrophic state. The heads of the supernumerary thigh-bones are in the same sockets as the natural ones, and consequently so close to them, that though the thigh-bones are distinctly double, the thighs down to the knee are simple. From the knee, however, the monstrosity is more striking, the additional limbs being perfectly separated from the regular ones. The left additional leg is ankylosed, and united to the regular one at a right angle; it is directed towards the right, and this is also the case with the foot, so that the external angle is turned downwards. The right additional leg is shorter and more closely united to the regular one; its direction is the reverse of that of the left, but it is more naturally formed, and has five toes, while the left has only two. Both legs seem to be immovable. Between the two natural nates there is a third over the rudiment of the additional pelvis; the anus is nearly below the middle of the third buttock, and the scrotum between the two left thighs; the testicles have not yet descended. There are besides three citatrices visible on the additional extremities, one longitudinal at the upper middle portion of the third buttock, another transverse on the thigh, and a third circular one on the left additional foot.

Though the occurrence of four lower or upper extremities, or both together, is not very rare, there exist but very few instances of the subjects affected with these monstrosities having lived, and in this sense the above case is very remarkable, the child being in good health and likely to do well. Some analogous cases are, however, related by medical authors; and M. Geoffroy gave a short enumeration of them; Aldrevandus, in his book *De Monstris*, mentions several instances of quadruped children, and gives, at page 535, the figure of one of them which was born at Rome; he also describes several cases of quadruped birds, some of which had even the power of using their additional legs. The *Recueil des Ecarts de la Nature* contains also the description of a quadruped chicken, the supernumerary legs being short and deformed; and that of a pigeon which used all four legs indiscriminately. There exists at this moment at Etampes a chicken, which is perfectly analogous to the above case, being provided with two thighs but having four thigh-

bones, and, besides the two natural legs, two accessory ones, which are anchylosed; in a goose also, from the collection at the *Jardin des Plantes*, the same anomaly is observed, but only on one side.

# ST. BARTHOLOMEW'S HOSPITAL.

## ERYSIPELAS AFTER ARTERIOTOMY.

JOHN SHERLOCK, ætat. 35, was admitted into Luke's Ward, under the care of Mr. Vincent, on Friday the 1st of October.

The upper and lower lids of the left eye were very much swelled, and of a brownish red hue; the left side of the forehead and nose, and the whole of the left cheek, were affected in the same manner. A partial view only of the eye could be obtained, the conjunctiva of which appeared slightly inflamed; he complained of severe burning pain in the inflamed parts; skin hot and dry; tongue white and furred; pulse 100, and rather hard; bowels constipated.

He states that, about two years and a half since, he was suddenly seized with a numbness of the left side of his tongue, which, in a few hours, extended to the face, head, arm, and leg of that side. This sensation, after remaining three or four days, left him, and then the arm and leg of the right side became similarly affected; this attack lasted about five weeks. In a few days afterwards he experienced "a dull pain" extending from the vertex towards the ear of the left side, which still continues. Since the accession of this pain, the left side of the face has been repeatedly affected with numbness similar to what he experienced in the first instance; he has also been subject ever since to loss of memory. He has been under the care of many medical men, has taken a great deal of medicine, and has been repeatedly bled from the arm, but has never experienced the slightest relief.

He came to the casualty ward of this hospital on the 24th of September, and complained of severe pain in the left side of his head; he had been advised by an eminent medical man of the city to have some blood taken from his temporal artery; his pulse being quick and rather full, the dresser opened the temporal artery of the left side, and took from it six ounces of blood, which produced syncope. After he had recovered from his faintness, which lasted about two minutes, he expressed himself as being very much relieved. The artery was then divided and secured in the manner recommended by Mr. Alcock. A dose of the mist. senn. comp. was given to him, and he left the hospital.

On the 30th of September he again ap-

peared at the casualty ward with a slight degree of redness and swelling of the upper lid of the left eye; a dose of house-medicine was given him, and a bread and water poultice ordered to be applied to the inflamed lid, and he again left the hospital. On the following day he returned in the state already described. To have a powder immediately of

*Ipecacuanha*, v. grs;  
*Calomet*, v. grs;  
*Jalap*, xxv grs;  
*Saline draught*, ʒij;  
*Solution tartar emetic*, ʒi.

This mixture to be taken every fourth hour.

Fomentations to the inflamed parts, and afterwards a bread-and-water poultice. Milk diet.

Oct. 2. The redness and swelling have extended to the forehead and scalp of the left side; bowels have been freely purged; skin hot and dry; tongue furred; pulse 100 and hard. Saline mixture, with a drachm and a half of solution of tartar emetic, to be continued every second hour. Continue fomentations and poultice.

Oct. 3. Vesications have appeared since yesterday in the lids of the left eye; the redness and swelling now occupy the *whole* of the forehead, and have extended to the lids of the right eye. The skin is still hot and dry; pulse and tongue the same as yesterday; bowels not relieved since Friday. The pain in the inflamed part is very severe.

Rx *Jalap*, gr. xxv;  
*Ipecacuanha*, gr. viij;  
*Calomet*, gr. vi, to be taken immediately.

Continue the saline draught, with ʒiij of sol. tart. emet. every third hour, to commence in two hours. Continue fomentations and poultice.

Oct. 4. He says that the powder purged him very much, and made him very sick; the nausea was increased by the first dose of antimony, and he remained very sick for about four hours, when a profuse perspiration broke out, and continued till this morning; his skin is now cool and moist; pulse 80 and soft; the inflamed parts are not so much swelled, and are of a much fainter hue; he says he feels quite comfortable. Ordered to take the saline mixture and antimony every six hours. Continue fomentations and poultice.

Oct. 5. Very much better in every respect. Ordered to discontinue the medicine.

Oct. 6. The vesications have burst, and the integuments beneath are occupied by numerous small sloughs; he is improving fast.

Oct. 8. The sloughs have separated, and the redness and swelling have nearly subsided.

Oct. 12. He has had no headach, loss of memory, or numbness since the bleeding from the temporal artery. The redness and swelling have entirely subsided; his appetite is good, and the several functions are now regularly performed. He says he feels much better than he has ever done since the first attack.

Oct. 16. Dismissed cured.

In this case there are two points particularly worthy of attention: the first is, the conjunctiva remained entirely unaffected, while all the surrounding parts, including both palpebræ, were occupied by the erysipelatous inflammation; the second is the super-vention of the erysipelas on the operation of arteriotomy, performed according to Mr. Alcock's directions, namely, by dividing the artery after a sufficient quantity of blood was abstracted, and then applying ligatures to the divided vessels.

## HOSPITAL SHIP "GRAMPUS."

### CASE OF DIFFUSED ANEURISM.

*Communicated by MR. BENNETT, Assistant Surgeon.*

JOHN MORGAN, *ætat.* 32, seaman, was admitted on board this hospital on the 28th Sept. 1830. His appearance emaciated and exsanguine; his countenance sallow and anxious. He complained of pain in the situation of a tumour, about fourteen inches in circumference, occupying the lower third and inner side of the right thigh, presenting its greatest bulk in that situation, and gradually decreasing forwards to the ham and outer side of the thigh. The circumference of the tumour had a defined, hardened, margin; the summit was tense, elastic, and gave to the touch an evident sense of fluctuation; the integuments retained their natural colour; the leg was somewhat œdematous, and remained flexed, without the power of extension. The patient denied that any morbid appearance, or uneasiness, had existed in the part previous to seven weeks since, when, without assignable cause, the whole leg and foot became swelled and tense, and ultimately "settled" into the present tumour. Upon the most careful examination no pulsation could be detected in the enlarged surface, except to a slight degree in that position which lay immediately over the seat of the popliteal artery. Pressure obstructing the passage of blood through the femoral artery produced no diminution in the bulk of the tumour, nor could any sound be detected upon application of the

stethoscope. The patient had no recollection of any pulsating tumour having ever appeared in the ham. He had had some severe rigours, and evidently suffered much constitutionally. Under these doubtful circumstances the limb was placed on a pillow, resting on its outer side, and the evaporating lotion applied. On the 29th, the tumour being in no way diminished, but rather more tense, the necessity became apparent of settling the question whether the tumour was occasioned by a collection of matter, or by disease of a more serious character. Preparations were, therefore, made to secure the femoral artery, should the tumour prove aneurismal upon introducing a lancet into its substance. This was done to the depth of an inch in a valvular direction, but with no other result than the escape of a few drops of dark blood. This attempt to ascertain the true nature of the disease having failed, adhesive plaster was placed over the puncture, and the limb restored to a state of rest, without any appearance of a disposition to hæmorrhage.

On the 30th, at noon, the patient having moved the limb roughly, and placed it over the side of his bed, about an ounce of fluid blood, unattended by arterial jet, passed from the aperture made in the tumour the day previous, and was easily checked by placing the limb in a quiet position, and by slight pressure with lint. The two following days were passed without any change in the appearance of the tumour, with the exception of a slight apparent extension towards the upper part of the thigh. A probe introduced into the lancet-orifice in the tumour, passed its entire length in every direction without resistance and without hæmorrhage.

On the 3d Oct., the swelling had extended considerably up the thigh, occupying its lower half, was much more tense at its original seat, and gave a more evident sense of fluctuation immediately above the patella. Under these circumstances Dr. Dobson, principal surgeon to Greenwich Hospital, who attended in consultation on the case, declared his opinion, that, taking into consideration the enfeebled powers of the patient, and the mass of disease in which the parts were evidently involved, the removal of the limb gave the only chance of recovery to the patient; and he having given his consent, amputation was performed on the same day by Mr. Bennett, assistant-surgeon to the hospital, in the presence of Dr. Dobson and Mr. Gilchrist. The limb was removed at the upper third of the thigh by the circular incision; about eight or ten ounces of blood were lost during the operation; ligatures were placed on the femoral, profunda, and three minor arteries,

During the operation the patient was much exhausted, and required the frequent exhibition of stimulants. When removed to bed, his pulse was feeble and skin cold; he spoke cheerfully, and appeared gratified at having lost the cause of his suffering. Half a drachm spt. ammon. arom., and forty drops of laudanum, given immediately after the operation, were instantly vomited, and vomiting continued troublesome for some hours. By the application of a mustard cataplasma and bottles of hot water to the epigastrium, with the exhibition of pil. opii, combined with but a small quantity of fluid, the stomach became tranquil, and retained beef-tea, with arrow-root and wine, given at short intervals. During the night reaction took place to some extent, the skin became warmer, and the pulse rose; he slept at intervals, and expressed himself free from pain.

At six a.m. on the 4th, he appeared to have rallied considerably, and expressed a wish for some tea and bread, of which he took a small quantity. At nine a.m. a state of collapse came on, and in two hours he expired.

Upon examination of the removed limb, between two and three pints of dark blood, partly coagulated and partly fluid, were found occupying the lower half of the thigh, nearly insulating the lower third of the shaft of the femur, which to the extent of four inches was denuded of periosteum, and presented a honeycomb appearance. The chief volume of effused blood occupied the situation of the muscles (which were nearly absorbed), and in many parts was in contact with the integuments, chiefly so immediately above the patella. Upon pursuing the examination, a fine aneurismal sac, about the size of a pullet's egg, evidently formed by a dilatation of the three structures of the artery, was found on the anterior surface of the popliteal artery; the sac, at its upper third and anterior surface, was rent to the extent of two inches in a transverse direction. Immediately above the torn sac, and externally, appearing to form a portion of it, was a second dilatation of the artery forming a sac, the size of a small walnut, lined with a thick layer of coagulum, and communicating with the larger and torn sac by an opening in size not exceeding a third of the natural calibre of the femoral artery. The cellular tissue of the leg and foot was loaded with serum.

#### *Inspectio Cadaveris.*

Enlargement of the heart, with general thinness of its muscular structure. The right kidney was placed immediately over the common iliac vessels of the same side. Other viscera were natural.

#### INQUEST ON MR. KINNENAR.

On Thursday, Oct. 21st, an inquest was held before Mr. Stirling, coroner for Middlesex, on the body of T. Kinnear, Esq., of Cornwall Terrace, Regent's Park. It appeared from the evidence, that the deceased had retired to rest on the previous Tuesday apparently in his usual state of health, but that on the morning of Wednesday, not rising at the accustomed hour, the man-servant, upon entering the chamber, found his master stretched upon the bed, to all appearance a corpse. His first impulse was to seek for medical aid, and having met Dr. J. Patterson, that gentleman, upon accompanying him to the house, found Mr. Kinnear dead in his bed, and a surgeon with him.

*A Juror.*—Can you tell the cause of his death, Dr. Patterson?

*Dr. Patterson.*—It is impossible, without a minute examination of the body. There were no appearances to indicate the cause of death; and I have no hesitation in saying, as an experienced physician, that the obscurity of the case renders a rigid investigation necessary.

*Mr. Lovegrove*, the surgeon, said he was called in, and found Mr. Kinnear quite dead. He could form no judgment as to the cause of death.

*By the Coroner.*—I have no reason to believe that he died by any other means than the visitation of God, but I have had no means of ascertaining.

A juror expressed his opinion that the body ought to be opened.

*Dr. Patterson* said, that in his opinion it was highly necessary—in fact it was indispensable to enable the jury to come to a right conclusion. He was a magistrate as well as a physician, and knew something of legal inquiries, and he would say boldly, that without a minute examination of the body, the inquisition would be a mere nullity.

The coroner and jury then proceeded to view the body, and on their return, Dr. Patterson was again questioned, and said, the appearances could not possibly enable any medical man to state the cause of death, since they might have been produced by various mortal diseases.

The room was then cleared of all but the jury, and the result of their deliberations was declared in a written paper, in the following terms:—"That the jurymen were of opinion that the body should be opened in the presence of Dr. Patterson and the parish surgeon, and any other medical man whom the family might choose to appoint."

A solicitor, who had been present from the commencement of the proceedings, submitted to the coroner whether there was any-

thing proved which could call for or warrant such an order.

The foreman of the jury (Edward King, Esq., of 34, Baker-street, Portman-square) said, that he and his brother jurymen were assembled to inquire upon oath into the cause of Mr. Kinnear's death, and he humbly conceived they were entitled to demand the best evidence. How else could they satisfy their own consciences, or the ends of public justice?

The solicitor again urged that in law the coroner alone had the right to order the dissection, and begged he would withhold that order in the present instance, as it was not proved to be necessary.

*Mr. Stirling* said, that if it was the unanimous wish of the jury, he certainly should not withhold the order, and he finally directed the body to be opened, and the inquest was then adjourned until Saturday evening at eight o'clock.

The presence of a reporter was objected to at the commencement by the solicitor, but the coroner refused to interfere.

On Saturday evening the jury again assembled, when Dr. Patterson presented the following report of the *post-mortem* examination of the body of the deceased:—

"After a minute and careful examination of the cavities of the body—viz. the chest, the abdomen, and the head, the chief morbid appearances that were observed are, an effusion of blood into the right and left cavities of the chest, amounting to about six ounces on the one side, and seven on the other, and a large accumulation of putrid blood in the stomach, mixed with its contents—half-digested food. The blood-vessels of the brain appeared more turgid than usual; these appearances on the head, however, were not sufficient to account for death. Upon mature consideration, the cause of the death of Thomas Kinnear, Esq., appears to us to have been the rupture of a blood-vessel on the stomach.

"James Patterson, M.D.  
George G. Sigmond, M.D.  
William Lovegrove, Surgeon.  
Alexander Watkins, Surgeon.  
A. Hamilton, Surgeon.  
J. Pelham Buckland, Surgeon."

The jury returned a verdict—"Died by the visitation of God."

## LITERARY INTELLIGENCE.

Dr. Gordon Smith is preparing for publication an abstract of Professor Chaussier's work on *Judiciary Necrotomy*.

## TO CORRESPONDENTS.

COMMUNICATIONS have been received from A Surgeon—Anonymous—A Constant Reader—P. R.—An Invalid Subscriber to THE LANCET—Dr. Weatherill.

A. We are well aware of the mean and petty tricks, and whenever we have been enabled to notice them, our animadversions have not been withheld.

*A Constant Reader.* Thanks. He will perceive that his hint has been anticipated.

*A Medical Student.* There are not any delivered in the summer which are "recognised" by the College of Surgeons. Two courses, as described, are not sufficient. It is now required that *two winters* should be devoted to surgical lectures. It is a heartless system of plunder.

*Mr. E. Brant.* No.

*A Medical Pupil.* Mr. Waller.

*Herodotophilus.* The difference between the heads of the two nations is considerable, and has been mentioned, we think, particularly by Blumenbach and Richerand. The cause of the difference, as stated by Herodotus, is not devoid of reason.

*An Inquirer.* No; he would be liable to the penalties named in the Act.

*G. E. E.* will find in page 5, No. 369, of THE LANCET, the information he requires.

*Machaon.* The probationary treatment, and the terms of the indentures, can alone determine the legal usage. There is no abstract unconditional law by which obedience to such practices can be enforced.

*Castigator,* in reply to the sneers of the "base Green Dub," directed against the great mass of the English medical practitioners, next week.

The letters which we receive weekly would occupy more than two entire numbers of our Journal; a very great portion, therefore, are unavoidably omitted. This omission, however, does not ultimately prejudice professional or public interests, because we generally avail ourselves, in some way or other, of all those facts and arguments, the publication of which may appear likely to benefit the public. This statement will be sufficient to explain to many valuable contributors, why their various communications have not been inserted. Correspondents should be informed, that from the nature of the arrangements for publishing a Journal of this description, so many thousands of which have to be folded, stitched, and ready for delivery by twelve o'clock on every Friday, there can be little chance of obtaining the insertion, in the "current Number," of letters consisting of more than a few lines, unless they are received at the office, on or before *Tuesday* in each week.

# THE LANCET.

Vol. 13

LONDON, SATURDAY, NOVEMBER 6.

[1830-31.]

## MEDICAL JURISPRUDENCE.

### PRACTICAL COMMENTARIES ON DR. CHRISTISON'S PROCESSES FOR DETECTING POISONS.

#### MURIATIC AND OXALIC ACIDS.

In the subsequent observations we shall pursue the same order as that observed in the previous article. We shall commence with Dr. Christison's remarks on the muriatic or hydro-chloric acid.

"Concentrated hydrochloric acid is at once known by its peculiar vapour or fumes, and still more delicately by the white fumes formed when its vapour comes in contact with ammoniacal gas. This test is applied by simply bringing near one another the open mouths of two bottles which contain the two substances. The yellow colour which it usually possesses is not essential.

"In its diluted state it is recognised with extreme delicacy by means of the nitrate of silver, which forms a dense white precipitate: a similar precipitate, however, is caused by the same test, with many other acids and their salts. The best method of determining the true nature of the precipitate for the purposes of medical jurisprudence, is to collect it on a filter and then to dry it and heat it in a tube. It fuses under the point of redness, and unlike all the other white salts of silver, remains at a red heat undecomposed, and, on cooling, forms a translucent mass which cuts like horn.

"The effects of mixture on the tests for hydrochloric acid have not been particularly examined. On the whole they will not prevent the tests being applied, but they will render the results doubtful, because very many organic substances, and particularly the mixture of food and secretion in the stomach, naturally contain the muriate of soda. Fortunately this is a matter of little consequence, for hydrochloric acid very

rarely comes under the cognizance of the medical jurist as a poison."

These directions require but little comment. As far as the contents of the stomach are concerned, no chemical evidence can ever be of value, since not only the muriates but the *free acid* itself has been detected by Prout, Tiedemann, Gmelin, and others, in the secretions of that organ. The morbid appearances alone therefore are to be taken into consideration. Neither is the evidence of *free* muriatic acid of any value, as regards vomited matters, in suspected cases, where recovery has taken place, and no morbid appearances can be observed, since in the acid eructations arising in dyspepsia and pyrosis, the muriatic acid has been recognised.

The case is, however, very different as far as regards a portion of liquid remaining in the unmixed condition, and here the appearances Dr. Christison describes are scarcely explained with adequate preciseness. The test of the ammoniacal vapour is certainly not sufficient by itself, as any one may prove by exposing strong nitric, sulphuric, or acetic acids to the same reagent, when a similar white vapour, though in a lesser degree, will be immediately formed. A portion of the acid should therefore be diluted, and to one part be added nitrate of silver, to a second nitrate of baryta: if a precipitate occurs in the former and not in the latter, the evidence of muriatic acid cannot be disputed, for reasons sufficiently apparent. A case may also occur, in which the subject of examination is a vessel which has been inverted, and to all appearance emptied of its contents, and from which only the minute quantity described in the first article on sulphuric acid can be obtained by the aid of the capillary tube. From this the nitrate of silver will procure a precipitate, but certainly not sufficient to demonstrate the for-

mation of the horn silver, in the manner Dr. Christison describes. Most other authorities direct the examination of this precipitate by its solubility in ammonia, a circumstance which Dr. Christison does not notice at all, possibly because the tartrate and phosphate are similarly affected. There is one property, however, which, coupled with the effect of ammonia, is quite sufficient to give certain proof; namely, the insolubility of the chloride in nitric acid. The minute precipitate we have alluded to, should therefore be dissolved in a drop of caustic ammonia, and an *excess of pure* nitric acid added, when the chloride of silver will be again precipitated, an action which would not take place with any other ammoniacal solution of that substance.

The analysis of stains will usually afford a sufficient quantity of chloride to form the horny mass, and in this instance the evidence is more satisfactory, inasmuch as a comparative analysis may be instituted on a sound portion of the same materials, and the difference in quantity be accurately observed.

The testing of the solubility of the precipitate on a very minute scale, we should recommend to be performed on a watch crystal in preference to a tube. The nitric acid employed, should be previously examined by the addition of a little nitrate of silver, to rid it of the muriatic acid which it usually contains.

Dr. Christison next cursorily notices poisoning by phosphorus and chlorine, but as he proposes no method for the detection of these, we shall not enter on their consideration, until we shall have commented on all the processes he describes; we shall then, in a supplementary article, advance original methods by which such poisons as he passes over may be detected. We also pass by iodine and the hydriodate of potash, as it happens that these have been already fully noticed in this Journal by a correspondent. We now proceed to the consideration of the oxalic acid. This subject Dr. Christison has himself investigated, and every line of the subsequent quotation is deserving of the most serious attention.

“Oxalic acid is commonly in small crystals of the form of flattened six-sided prisms, transparent, colourless, free of odour, very acid to the taste, and permanent in the air. Two other common vegetable acids, the

citric and tartaric acids, differ from the oxalic in being seldom regularly crystallised, and never in fine prisms. In general appearance it resembles the sulphate of magnesia, for which it has been so often and so fatally mistaken.

“In determining the medico-legal tests for oxalic acid, it will be sufficient to consider it in two states,—dissolved in water, and mixed with the contents of the stomach and intestines or vomited matter. If the substance submitted to examination is in a solid state, the first step is to convert it into a solution. In the form of solution its nature may be satisfactorily determined by the following process. The acidity of the fluid is first to be established by its effect on litmus paper. This being done, the reagents might be applied at once. But it is better to neutralize the acid previously with any alkali, for then they act with greater delicacy. The remainder of the process consequently applies not only to oxalic acid itself, but also to the soluble oxalates, which will presently be proved to be likewise active poisons. The tests are the hydrochlorate (muriate) of lime, sulphate of copper, and nitrate of silver.

“Hydrochlorate of lime causes a white precipitate, the oxalate of lime, which is dissolved on the addition of a drop or two of nitric acid, and is not dissolved when similarly treated with hydrochloric acid, unless the acid is used in very large proportion. The solubility of the oxalate of lime in nitric acid, distinguishes the precipitate from the sulphate of lime, which the present test might throw down from solutions of the sulphates. The insolubility of the oxalate of lime in hydrochloric acid, on the other hand, distinguishes the precipitate from the tartrate, citrate, carbonate, and phosphate of lime, which the test might throw down from any solution containing a salt of these acids. The last four precipitates are re-dissolved by a drop or two of hydrochloric acid; but the oxalate is not taken up till a large quantity of that acid is added.

“Sulphate of copper causes a blueish-white precipitate, which is not re-dissolved on the addition of a few drops of hydrochloric acid. The precipitate is the oxalate of copper; it is re-dissolved by a large proportion of hydrochloric acid. This test does not precipitate the sulphates, hydrochlorates, nitrates, tartrates, citrates; but with the carbonates and phosphates it forms precipitates, resembling the oxalate of copper. The oxalate, however, is distinguished from the carbonate and phosphate of copper, by not being re-dissolved on the addition of a few drops of hydrochloric acid.

“Nitrate of silver causes a dense white precipitate, the oxalate of silver, which;

when collected on a filter, dried, and heated, becomes brown on the edge, then fulminates faintly, and is dispersed. The object of the supplementary test of fulmination, is to distinguish the oxalate of silver from the numberless other white precipitates, which are thrown down by the nitrate of silver from solutions of other salts. The property of fulmination, which is very characteristic, requires, for security's sake, a word or two of explanation in regard to the effect of heat on the citrate and tartrate of silver. The citrate when heated, becomes altogether brown, froths up, and then deflagrates, discharging white fumes, and leaving an abundant ash-grey, coarsely fibrous, crumbly residue, which on the further application of heat, becomes pure white, being then pure silver. The tartrate also becomes brown and froths up, but does not even deflagrate, white fumes are discharged, and there is left behind a botryoidal mass, which, like the residue from the citrate, becomes pure silver when heated to redness. Another distinction between the oxalate and tartrate is, that the former is permanent at the temperature of ebullition, while the latter becomes brown. The preceding process or combination of tests will be amply sufficient for proving the presence of oxalic acid, free or combined, in any fluid which does not contain animal or vegetable principles.

"Of the modifications which are rendered necessary by the admixture of such principles, none are of any consequence, except those acquired in the case of an analysis of the contents of the alimentary canal or matters of vomiting. Here a word or two must be premised on the changes which the poison may undergo, in consequence of being mingled with other substances in the stomach or intestines. There may either be organic principles contained in the body, or substances introduced into the body as antidotes."

"As to animal principles, Dr. Coindet and I have proved, that oxalic acid has not any chemical action with any of the common animal principles, except gelatine, which it rapidly dissolves, and that this solution is a peculiar kind, not being accompanied with any decomposition either of the acid or the gelatine. Consequently oxalic acid, so far as it concerns the tissues of the stomach or its ordinary contents, is not altered in chemical form, and remains soluble in water. In such a solution, however, a variety of soluble principles are contained, which would cause abundant precipitates with two of the tests of the process—sulphate of copper and nitrate of silver; so that the oxalates of these metals could not possibly be exhibited in their characteristic forms. The process for a pure solution, therefore, is inapplicable to the mixtures

under consideration; but changes of still greater consequence are effected in the poison, by exhibiting antidotes during life. It is now, I believe, generally known, since the researches of Dr. Thomson and those of Dr. Coindet and myself, that the proper antidotes for oxalic acid are magnesia and chalk. Each of these forms an insoluble oxalate, so that if either had been given in sufficient quantity, no oxalic acid will remain in solution, and the proof of the presence of the poison, must be sought for in the solid contents of the stomach, or solid matters of vomiting. The following process for detecting the poison will apply to all the alterations which it may thus have undergone."

"The first object is to procure a solution. If an antidote has not been given, the contents and tissues, or vomited matter, are to be boiled, distilled water being added if required; the acid is then to be neutralized with potass, and the whole filtered. If magnesia or chalk has been given as an antidote, the insoluble matter is to be separated by filtration, and boiled for twenty minutes in a solution of carbonate of potass, in eighteen or twenty parts of water. A double interchange of elements takes place between a part of the carbonate of potass, and a part of the oxalate of lime or magnesia, and in consequence, some carbonate of lime or magnesia is thrown down, while some oxalate of potass will be found in solution. The fluid after filtration is to be acidulated with pure nitric acid, oxalic acid being now in solution, whatever may have been its original state; the next step is to separate it from the animal and vegetable matter dissolved along with it. I have tried various plans for this purpose, but have found none to answer so well as precipitation with the muriate of lime, so as to procure an oxalate of lime, which, after being well washed, is to be decomposed by boiling it in a solution of carbonate of potass, as before. An oxalate of potass will again be found in solution. The excess of alkali is finally to be neutralized with nitric acid. The fluid is now to be tested with the three reagents for the pure solution of oxalic acid."

In this series of experiments, Dr. Christison is entirely original, and little can be added, either in the way of comment or alteration, to that part which relates to the properties of the acid in pure solution. We have omitted in the quotation his observations on the distinguishing properties of the oxalic acid, and the sulphate of magnesia, because he relies entirely on the tasting of the solution, and this precaution, though extremely unpleasant, should, certainly, be

invariably observed in preference to any chemical experiment whatever. There is one property, however, of which Dr. Christison makes no mention, and which eminently distinguishes oxalic acid in the mass from any other chrystalline substance with which we are acquainted, namely, that when thrown into water, its particles explode with a sharp crackling sound, and are dispersed in every direction; this phenomenon is very remarkable, and is particularly noticed when the water is poured over the oxalic acid.

In the course of our experiments on this subject, we noticed a beautiful property of the oxalic acid, which is applicable especially to the recognition of a very minute particle of that substance when found in the pure state, and which, when coupled with the evidence of the fulmination with silver, is perfectly free from the slightest imputation; we mean the property which oxalic acid possesses of being precipitated in singularly beautiful stellated crystals by caustic ammonia; if, therefore, *as often occurs in practice*, a minute crystal, say the 50th of a grain in weight, be found adhering to a paper, or accidentally scattered on the table where the admixture was made, by dissolving this in a drop of distilled water on a watch crystal, testing it with a particle of litmus paper, and adding a drop of *strong* caustic ammonia, a beautiful radiated star is immediately produced; by increasing the quantity of water this is dissolved, and by holding it for a moment over a small spirit-lamp flame, the excess of ammonia is dispelled, and a dry oxalate remains behind; this being dissolved again, and tested with the nitrate of silver, a white precipitate is produced, which, when dried in a water bath,\* and held over the spirit-lamp again, fulminates in the characteristic manner, and is entirely dispersed.

This method possesses, in point of manipulation, considerable advantages over that which Dr. Christison recommends; one of these is, that it combines the evidence of two decisive properties of the acid, in experiments performed consecutively on the same particle and in the same vessel. With reference to the ammonia test we may add,

that we believe it to be, by itself, sufficient evidence of oxalic acid in any solution which reddens litmus paper. We have tried every acid we could procure, and with none observed at all similar indications. Its evidence, however, is not available in organic mixtures, as it does not operate when gelatine is present.

Further, with respect to the pure solution, it will be observed by experimentalists, that the oxalates of lime and copper are distinguished from phosphates, etc., in Dr. Christison's text, by the comparative quantity of nitric or muriatic acid, in which they are soluble; a larger quantity producing the effect which, in a small quantity, is considered a distinguishing feature. We need not observe to what teasing objections this circumstance may expose the evidence of an inexperienced chemist.

With respect to the detection of the acid in complex mixtures, and after an antidote has been administered, a difficulty of great importance has been started by no less an authority than Gay-Lussac (*Le Globe*, 22 *Juillet*, 1829), who states, that when animal matter is heated with caustic potash, oxalic acid is generated. A question hence naturally arises, whether the *carbonate* of potash may not have the same effect. If this be decided in the affirmative, the process above quoted becomes worse than useless. In a brief appendix to his book Dr. Christison notices the objection, but advances no explanations whatever. To supply this defect, we have instituted experiments on the several animal proximate principles, individually and collectively, and have never noticed the slightest traces of oxalic acid in the fluids thus submitted to the action of the carbonate of potash. This difficulty, therefore, as far as our experiments warrant, is not applicable, unless the supposed carbonate contains, as is frequently the case, a portion of the alkali in the caustic state.

All objections may, however, be obviated by attention to the manipulation of the materials; the mixture should be filtered, and the solid parts then diluted with water, triturated together, and agitated in a suitable vessel, when the heavy oxalate of lime will invariably subside, and may be mechanically separated from the other ingredients; wash-

\* We shall furnish an engraving of an extremely convenient bath, when we come to the detection of arsenic.

ing with water will now carry away every trace of animal matter.

Another important circumstance here requires notice, which though not mentioned in the work before us, has we are informed been made the subject of observation by the distinguished author in his subsequent course of lectures. When solid carbonates are mixed in excess with oxalic acid, it rarely or never happens that the acid is perfectly neutralized; consequently a portion remains in solution, although oxalate of lime may have been abundantly formed. We have found this to occur when carbonate of lime was stirred up with thick soup containing the acid, and allowed to remain in contact with it for twenty-four hours. Hence the reason for filtration as noticed in the preceding paragraph, and hence arises the necessity of two distinct processes being instituted in every case; viz., one for the filtered acid fluid, a second for the oxalate of lime remaining on the filter. Of the latter we have already disposed, the former requires particular consideration.

Dr. Christison has, we understand, directed his class to precipitate the acid fluid by the acetate of lead, to wash, filter, suspend the precipitate in a little distilled water, and decompose it by sulphuretted hydrogen. Sulphuret of lead is thus formed and oxalic acid set free, which may be separated, he states, by filtration and subsequent boiling.

On repeating this process we find that it is liable to some objections. In the first place, in all organic fluids the muriate of soda exists to a great extent, and in the present case always accompanies the free oxalic acid in the fluids of the stomach; the acetate of lead therefore throws down not merely an oxalate but a chloride of lead, and this, when decomposed by sulphuretted hydrogen, sets free not only oxalic but muriatic acid; the application of the silver test thus becomes obscured by the formation of a chloride as well as an oxalate of silver. The evidence of the colour of the precipitate goes for nothing, the fulmination is interfered with, there is no total dispersion, which should take place, and the phenomena are so different, as not to be entitled to the same confidence as under other circumstances. For these reasons we prefer to precipitate the acid fluid by the muriate of lime; thus an oxalate of

lime is formed, while the muriate of soda remains in solution. This oxalate of lime must then be decomposed by carbonate of potash in the manner already described. Finally, in all neutralizations, we would strongly recommend the nitric acid to be avoided, and the acetic acid to be used in its stead.

As in the case of sulphuric acid we have noticed a source of fallacy which may arise from the previous employment of sulphates, we have to observe another in the present which may exist if rhubarb have been administered before death. M. Henry has found in different specimens as much oxalate of lime as from 29 to 32 per cent, and we have ourselves obtained  $1\frac{1}{8}$  grn. from 10 grains of Turkey rhubarb. The importance of this fact in medico-legal analysis needs no explanation. The difficulty it occasions can only be obviated by proving that no rhubarb in substance has been taken, or if any taken, what quantity was employed.

We are not aware that any compound of oxalic acid has ever been detected in the natural or morbid contents of the intestinal canal; its frequent occurrence in the urine, in combination with lime, will frustrate the medico-legal application of any search for it in that fluid.

No particular apparatus is necessary in the previous analyses. In the next article we shall discuss the mode of detecting arsenical preparations.

## CLINICAL LECTURES

DELIVERED AT

*St. Bartholomew's Hospital,*

BY MR. LAWRENCE.

*October 29, 1830.*

### CANCER OF THE LIP.

MR. LAWRENCE commenced by adverting to the case of cancerous lip, mentioned at a former lecture. The operation had been successful; a cicatrix had formed, and the removal of the part had not been attended with much deformity. The edges were now raised nearly to a level, and the only thing to notice was a slight indentation. The disease seemed to have been brought on by mechanical irritation, consequent on the habitual practice of smoking, to which the

man had been not only addicted, but devoted. It was worthy of notice, that the induration of the skin had occurred at the very part of the lip against which the end of the pipe had so constantly rested; for the patient did not follow the more *genteel* method adopted by some of the audience present, and for their sakes it was to be hoped that the practice of *cigar-smoking* was not so dangerous as that of the common pipe.

#### SCIRRHOUS ERREAST.

Another case was that of a patient about 50 years of age, who had felt some uneasiness in the chest for about a week. On feeling the breast, a small, perfectly hard lump was discovered on the axillary side of the nipple, which, she said, gave her not much pain. There was that peculiar hardness about this tumour which is so characteristic of scirrhus, and which has led to the vulgar appellation of "stone cancer." When it was said that the pain had existed only a week, it must not be supposed that the disease itself was only of a week's duration; for there are many instances in which, although the scirrhous state must have existed for many years, the patients had been free from uneasiness. There was one case in particular, where the disease had been of eight years standing, but yet the pain had only come on about a year and a half out of that period. This, the lecturer observed, was scirrhus in the early stage, and although the tumour formed so small a part of the breast, yet it would be seen that the whole of the mammary gland had been cut away, which was always advisable in such instances; for it was necessary to excise so much that the remainder would only be in the way, and, at the age of this patient, could be of little service. Another point to be observed in this operation was, not to preserve the whole of the skin, as there would then be a superfluous quantity, but to make an elliptical incision, so as to get rid of about half of the integument. [Here Mr. Lawrence cut into the tumour, which was lying on the table.] This, he said, is a very genuine specimen of scirrhus. The peculiarities are not so distinguishable by candle-light but you will find the structure compact and dense, and presenting to the knife the consistence of cartilage, rather than the soft and compressible natural state of the part. This is not a tumour in the gland, but a conversion of the substance of the gland itself into a perfectly incompressible, dense, structure."

#### BRONCHITIS.

The lecturer next proceeded to detail two cases of severe *bronchitis*. The first was

that of a man in Darker's Ward, who was the subject of scrotal hernia, and had been admitted under the care of Dr. Hue for disease of the chest. The second was that of a female, who was at the same time labouring under syphilitic disease. Mr. Lawrence said, that he had already observed there were not two kinds of pathology, one for the *inside* and another for the *outside*, but that the same principles which governed the treatment of external inflammation, are efficacious also in internal inflammation; and these cases of bronchitis were good examples of the reasonableness of this statement. He had treated them both by the antiphlogistic method, blisters, leeches, and purgatives, the result of which was, that the man was discharged well, and the female had been brought to a quiet state and good respiration, whilst the syphilitic ulceration had also disappeared.

There is at present, said Mr. Lawrence, in Darker's Ward, a very fine specimen (if I may so speak) of

#### PHLEGMONOUS ERYSIPELAS.

The patient is John Reed, a bootmaker, about thirty years of age. He began to feel uneasiness and soreness in the arm on the 19th of the present month, and was troubled with very great pain. On the 20th he rose early in the morning, with the intention of proceeding to his work, but he felt such headache, and was so oppressed with giddiness, that he fell down, and instead of going to work he went to the doctor. The redness, and soreness of the arm increased, extending upwards towards the shoulder, and downwards to the wrist. He got much worse, and, on the 21st, the professional gentleman who had cupped him in the neck, sent him to the Fever Hospital as a case of fever. Here he was bled in the opposite arm, and on the 27th, having been requested to see him, I found the upper extremity in a terrible state from very extensive erysipelas, and a more serious case, I think, never came under my observation. When I visited him the whole limb was enormously swelled, and the palmar surface of the fore-arm, and the same surface of the upper arm, were suffused with a bright-red colour. I cannot say, however, that the whole extent was thus coloured, on account of the great number of bullæ scattered over the surface, resembling the vesications produced by a blister. These bullæ had been pricked, and the fluid had escaped, but there were several which had since arisen, and the skin surrounding them was of a vivid scarlet hue. In this state about three-fourths of the fore and upper arm were involved; and when you consider that they were swollen to double the usual size, you may form some idea of the extent

of the vacicated surface. There was great hardness about all these parts, and that peculiar feel to the touch which may be designated *brawny*, and the state of the integuments and cellular tissue so different from that which characterises *simple* erysipelas. Now in the case of the patient afflicted with simple erysipelas, of whom I spoke last week, although the tumefaction was very considerable, yet the feeling was soft, and there was a "pitting" upon pressure. In the present case, however, there is a sensation of toughness, firmness, and, as I before said, it appears to the touch of the consistency of *brawn*. This clearly shows that there is an affection both of the skin, and of the cellular tissue beneath it. The vesications are most characteristic of the disease of the integuments, and the firmness points out its extension to the cellular tissue. When I saw the patient at the Fever Hospital there was a quietness and calmness in his manner, and a clearness about his eyes, which plainly indicated that he was not the subject of *fever*; and there was only that slight degree of feverishness which is usually excited by a severe local disturbance.

One of the most prominent circumstances in this case, is the acceleration of the pulse. When I first saw him, the beats were about 140 in a minute; at the present time they are slightly increased, being perhaps from 140 to 150. The sensorium is scarcely disturbed; when questions are put to him, he gives a clear and ready answer. Neither does the alimentary canal appear to suffer any disturbance; his bowels are regular, and there seems to be no marked disorder of the system. Indeed there is much less constitutional injury than we might have expected to find; and it is this circumstance which leads me to sugar favourably of the result, although very great destruction must occur of the integuments, and substance of the upper and fore-arm. There is one thing which strikes me as a peculiar feature in this instance. I cannot trace any immediate cause of the present erysipelatous attack. Erysipelas, in most cases which I have met with, has followed some direct irritation, bruises, or some external injury, or it has supervened upon ulcers, or some local disease already existing. Now the patient not being in a state to answer questions without inconvenience, I am not quite clear upon the point, but this seems to me to be a case of *spontaneous* erysipelas.

The only efficient treatment to be pursued, was that of making incisions throughout the whole length of the affected part, and these were freely made, in the first place, from the axillary extremity to the elbow. In cutting through the cellular tissue, there was that kind of resistance to

the knife which is felt in dividing a firm, brawny substance, and that yellow colour which is a pretty sure indication of mortification. In general you find the cellular tissue of a red tint, quite different from the bright pale yellow which is observed in this instance. I made another incision from the elbow towards the wrist, and here too the tissue was in the same condition. I should mention that the knife was carried completely through the stratum of tissue down upon the muscles, and the edges of the wounds, soon after the operation, gaped to the extent of half an inch. The bleeding was not so great as in the generality of instances; indeed the vitality of the part was so much destroyed, that the period for profuse hæmorrhage was passed. You should be given to understand, that when a large portion of cellular membrane has been deprived of its vitality, it is apt to slough, and the integuments covering that part frequently follow the same course; and the cause of this is, that the nutrient vessels of the skin are destroyed by the sloughing of the cellular substance.

The arm, after having been covered with wet cloths, was enveloped in a poultice. I ordered the patient some opening medicine, and afterwards a saline draught.

When I saw this patient to-day, I found that he had passed a comfortable night, free from pain, although he had not had much rest. His pulse continued in the state of frequency mentioned before, and a further extension of the inflammation appeared to have taken place, which rendered necessary further incisions, lateral and longitudinal, and these were followed by more copious bleeding than before. There is a more complete sloughing of the skin consequent on the loss of vitality.

If you can get a free discharge of matter, that will contribute in a great degree to the favourable progress of these cases; and if a local stimulus of resin-ointment be applied, a good effect will be produced. That plan then has been pursued here; and strips of plaster, with the yellow basilicon ointment, have been placed in the wounds. As his pulse to-day was nearly 150, feeble, countenance pallid, and as there was a state of general debility, I thought it advisable to prescribe cordials and stimuli. We always find a degree of correspondence between the local and general disturbance. Where severe local inflammation exists, we find an excited state of the constitution; and when mortification has occurred, we find that condition of the general system described as debility. I desired that the patient should have a tablespoonful of brandy to three of water. I also ordered him the sub-carb. amm., and twenty drops of the tinct. opii, the object of which was to support the constitution,

and to afford him some sleep, the want of which he complained of. I understand he was asleep this evening when I came to the hospital.

#### BLISTERS IN ERYSIPELAS.

The female patient, M. Robinson, the subject of simple erysipelas, whose case I mentioned last week, has been proceeding under the same treatment then adopted—leeches and opening medicine. There is a pretty considerable diminution of the inflammation, but it has extended down upon the foot, and up over the knee. In this case I have adopted a plan in great favour with the French, of applying a blister over the boundary between the inflamed and sound parts, with the view of stopping the further progress of the affection. This object, if attainable, would be much to be desired, because the inflammation generally travels from the extremities to the trunk, and consequently may be attended in the end with considerable danger. If therefore we apply the blister extending about an inch and a half over the sound upon diseased parts, and thereby prevent the increase of the local and general disturbance, we shall accomplish a great benefit.

The blister was put on the day before yesterday, but was not extended all round the limb. It appeared to me yesterday that the state of the leg was improved, and that the blister had effected the object. To-day, however, the inflammation seems to have passed a little above it. The same state of general debility appears to exist in this patient as in the last subject of our consideration, and I therefore ordered the subcarbonate of ammonia and the camphor mixture, which I think preferable for young persons, as the subcarbonate of ammonia is a kind of intermediate stimulus that may be employed with greater safety than wine or alcohol. Indeed, so safely may it be used, that some persons of good experience adopt it in a general manner, in small doses every two or three hours, in all stages of erysipelas; and some even go so far as to make use of it as an external application in the form of a lotion.

#### TRIAL OF JOHN LONG, THE QUACK.

*OLD BAILEY.*—Saturday, Oct. 30.

[Before Mr. Justice PARK and Mr. Baron GARROW.]

THIS being the day fixed for the trial of this person, charged with occasioning the death of Miss Cashin, the Court was tolerably fully attended. To the credit of the sound sense and excellent taste of the ladies

of the metropolis, we may observe, that there were not more than five or six females of even *apparent* respectability amongst the spectators.

Precisely at nine o'clock the prisoner, who had been out on bail, was put to the bar. The indictment charged him with administering to Catherine Cashin, spinster, a dangerous liquid, rubbing, washing, and sponging her back with the same, in consequence of which a wound, of the length of nine inches, of the width of seven inches, and of the depth of two inches, was inflicted on her back, of which she languished and died. He was also charged, on the Coroner's Inquisition, with the like offence.

The prisoner pleaded Not Guilty, in both cases.

Mr. ALLEY and Mr. C. PHILLIPS appeared for the prosecution; and Mr. GURNEY, Mr. Serjeant ANDREWS, and Mr. ADOLPHUS, for the prisoner.

Mr. C. PHILLIPS stated, that the prisoner stood charged with manslaughter, to which he had pleaded "Not Guilty."

Mr. ALLEY characterised this as one of the most important cases that had ever come within his long practice. The prisoner was charged with administering a noxious wash to the back of the deceased; and the question for them would be, whether that had been done unlawfully. The young woman was of a most respectable family in Ireland; her younger sister, labouring under indisposition, was recommended to try what change of air would do, and they accordingly came to London, where they resided, in the neighbourhood of the Hampstead-road.—Catherine Cashin occasionally attended her sick sister to the prisoner's house, under whose care the latter was. The deceased at that time, as he should distinctly prove, was in perfect health, of fine form, and firm flesh and muscle. The prisoner, however, in a short time told a person that if she did not put herself under his care, she would, in the course of two months, be in a rapid consumption. For a long time she hesitated, but at length, frightened by the declaration of the prisoner, she went to his house on the 3d of August, and was rubbed between the shoulders and on the back. On the 9th and 10th, the pain was so intolerable, that she wanted the prisoner to be sent for. She was, however, persuaded to wait till the 13th. On that day the woman of the house where she lived went to the prisoner, and told him that a dangerous ulcer was formed, and that the pain was great. His answer was, "Oh, it's all right; it is part of my system;" and he refused to do any thing, as it would interrupt the course which he wished it to take. On the 14th, she became so ill that she was confined to her bed. The prisoner was sent for, and he looked at the

wound. A large black spot was pointed out in the middle of the wound, and it was hinted that it looked like the commencement of mortification. He said, "Oh, no, it's all all right;" and added, that he would give 100 guineas to have other patients in the same state. After his departure, Mrs. Roddis, the woman where she lived, applied a poultice, in the hope of relieving the pain, but it did no good. Mr. Brodie was then sent for, but he (Mr. Alley) had not a sufficiently accurate statement of that gentleman's evidence to enter into a description of it. The next day the prisoner was sent for again: he found fault with Mr. Brodie's having been sent for, and refused to give any medicine, but recommended a tumbler of port-wine. Mrs. Roddis remonstrated, but he persisted in his prescription; a glass of wine was administered, but it was immediately thrown off the stomach. The next day he was sent for again: he exposed the wound by throwing off the bed-clothes in no very gentle or decent manner; and when spoken to about it, he said that it was necessary to expose the wound to the air. He then called for a rag, and was about to do something to the back, when Miss Cashin said, "Mr. Long, you shall not again touch me; my back you have much injured; it is horrible; for you well know that when I became your patient I was well and comfortable, and now you see my state." The prisoner then departed, and the next day the poor thing died. Mrs. Roddis, in the morning, heard the bell ringing violently, and running up stairs quickly, she found her in the agonies of death. Some difficulty was felt as to the case; and it was finally thought right to hold a Coroner's Inquest on the body. What took place at that inquiry it was neither his wish nor his duty to state; suffice it to say, the verdict of that Jury had been manslaughter, and the prisoner was now, in consequence, put on his trial. In addition to these facts, he should be able to prove, that the prisoner had himself stated to the brother of the deceased, that it was on his recommendation that the wash had been used. Mr. Alley then alluded to the examination of the body by the medical men, and he stated that they would all tell the Jury that the cause of the poor girl's death indisputably was the wound on the back. This was, in brief, an outline of the circumstances of the case as far as the facts went. He was sure that the Jury were free from all prejudice; but there was a notion prevalent abroad, that if a man, who was not a regular practitioner, administered to a patient, who subsequently died, he was guilty of a felony. This, however, was a mistaken notion, as was shown by Lord Hale, in his comments on a contrary remark made by Lord Coke. He wished to put this

point broadly and fairly to the Jury, because it was not on that ground he wished to procure a verdict. The criminal law of England, however, was so jealous of the lives of the King's subjects, that it enacted that if the act that caused the death of an individual was done heedlessly and incautiously, the agent was guilty of manslaughter. In his apprehension the conduct of the prisoner was much more than heedless and incautious; and he asked whether any man in his heart could say (if he proved the facts which he had stated) that this was not a case of manslaughter. It was well laid down by one of the best writers on the subject, that an act in itself lawful might become unlawful by the want of due care and caution. This rule he begged leave to apply to medical men; for whatever their skill or their science might be, they were bound to act with due caution. God forbid that he should say that due allowance was not to be made for the judgment and conclusions of a medical man; but when it went on to carelessness and neglect, he held with great confidence that the practitioner would be answerable in the eye of the law. One of the facts most to be remembered in this case was, that the act had been sought by the prisoner himself; the young woman was in good health, and it was on his representations that she had submitted to the operation; therefore it could not be said that he had been urged on by a desperate case to adopt a desperate remedy. The following witnesses were then called:—

Mary Ann Roddis, examined by Mr. C. PHILLIPS.—I am the wife of Mr. George Roddis, of No. 32, Mornington Place, Hampstead Road. In the month of June the Miss Cashins came to lodge in my house; the elder was called Catherine Cashin; her death is the subject of this inquiry. They came to lodge with me on the 26th June; deceased then appeared to me to be in perfect health; she so continued till within four or five days of the time, when I went with her to Mr. Long; we went there on Friday, 13th of August; Mr. Long at that time lived at 41, Harley Street; we saw Mr. Long; Miss Cashin introduced me to Mr. Long; Mrs. Cashin had requested me to accompany her daughter, and express to Mr. Long her fears respecting the wound on her daughter's back; I expressed this to Mr. Long; Mr. Long said Miss Cashin must go and inhale, after which he would go and look at her back; I went with her during the time she inhaled, and after that Mr. Long had her in another room; when I went into the inhaling room, there appeared to me to be two cabinet pianos; each lady took a pipe of about a yard and a half long, and put it to an orifice in the machine, opposite to which she placed a chair, and ap-

plying the pipe to the orifice, she inhaled; there were about eight or ten ladies in the room when I was there; Miss Cashin was from half an hour to three-quarters inhaling; after this, went into a room down stairs, into which I did not go; as we were going to the carriage, Mr. Long expressed a wish that Miss Cashin should come to his house every day, for the purpose of inhaling; Mr. Long also added, that she would be well in a few days; the next day, in consequence of something deceased said to me, I wrote to Mr. Long; he came to my house between five and six in the evening of that day; he saw the deceased in my presence, and examined the state of the wound on her back; he said it was in a beautiful state, and that he would give a hundred guineas if he could produce a similar wound on the persons of some of his patients; I directed his attention to a portion of the wound which had a dark inflamed appearance; he said it was the consequence of inhaling, and unless those appearances were produced, he could expect no beneficial result. At that time the wound and inflammation appeared to be about six inches by four; I told him that I had applied a poultice of bread and water, with a large portion of hog's-lard in it, and that I had given her saline draughts; he said that I had done very wisely; I asked Mr. Long what was to be done to allay the irritation of the stomach; he said he had heard of no irritation of the stomach; I told him that in my note I had expressed the words "unceasing sickness;" he said I had not; but on referring to the note, which he had with him, he found that I had stated it; he said that the sickness was of no consequence, but on the contrary a benefit. I begged that he would order something to quiet the stomach and bowels; he said it was all the consequence of inhaling, and that those symptoms, combined with the wound, were proofs that his system was taking due effect; I begged him to give her a composing draught, to which he replied, "that a tumbler of mulled port-wine was a better composing draught than all the doctors in the world could give, for he hated the very name of physic." On the stairs Mr. Long requested that I would expose the wound to the air; when he told me to give the mulled port-wine, I objected, but he insisted on its being given; I gave her a wine-glass full, which was immediately rejected by the stomach. When he told me to expose the wound to the air, he added, that I was to lay on a piece of linen, and keep a continual application of cream; I said that to expose a wound like that to the air would produce madness almost. He then said, that on reconsidering, he thought there could not be a better application than the poultice I had already made, and he requested that I

would continue it, and he should rely on my judgment for an account of the wound on the following morning; he stated, that as I had constantly applied the poultices, I should be better able to form a correct opinion than he should; he then took his leave. I applied the poultice as he desired; Miss Cashin, however, got worse. Mr. Long came on the following morning (Sunday, the 15th), between eleven and twelve; he went into Miss Cashin's bed-room, and I was there also; Mrs. Cashin was also there; on going into the room he very hastily took off his coat, and threw it on the bed; he requested some soft dry linen to be procured; he had asked me how Miss Cashin was, and I said she was worse; he then very unceremoniously stripped off her night-dress; he did not do it gently—he did it very rudely—as I never saw a medical man do in my life; I begged he would step aside until I removed the poultice; Miss Cashin said, "Indeed, Mr. Long, you shall not touch my back again—you very well know that when I became your patient I was in perfect health, but now you are killing me." Mr. Long replied, "Whatever inconvenience you are now suffering, it will be of short duration, for in two or three days you will be better in health than you ever were in your life," and again spoke most confidently that the result of his system would be to prolong her life; he then put on his coat; he said, alluding to her stomach and bowels, that those were the symptoms he wished to produce, and that they were the proofs that there were the seeds of consumption in her; I pointed out to him again the same spot in the wound that I had pointed out to him on the Saturday; the spot was then darker, and the wound had materially extended in that interval; he said that probably a number of boils would come out, which would be the consequence of inhaling, and which he wished to produce; he added that she was going on uncommonly well; the linen had been brought, as he desired, but he made no use of it; during this time Miss Cashin's back was lying exposed, altogether from ten to fifteen minutes; Mrs. Cashin again pressed the sickness on his attention; he said that he had a remedy with him which would stay the sickness, but that he would not then apply it, for it would be of ultimate benefit to her, and he liked the sickness; Mrs. Cashin said—"Good God! Mr. Long, why don't you now apply it?" He said he had visited a lady who had had sickness for six weeks, and she was better for it; he added that our fears were perfectly groundless, for no one could be doing better than Miss Cashin was; he then ordered some rhubarb and magnesia for her bowels; before he went away, he said that if the sickness was not over before

eleven or twelve that night, he would call and give her something to stop it; this interview was on the Sunday morning, and she died about ten on the Tuesday morning; he called again that night about eleven or twelve; she was still labouring under the sickness, and he gave her some medicine that he brought with him, but it was thrown off the stomach before Mr. Long left the room. In the morning of the Sunday she appeared to me to present a very restless and distressed appearance—tumbling and tossing about the bed; in the evening and through the day she had been getting gradually worse; I told Mr. Long that I thought the nervous system was so much affected that something ought to be done, and that probably some medicine might be given with effect; he said my fears were perfectly groundless—that it was my ignorance of his system, and that she would be perfectly well in two or three days; I was with her that night till past two o'clock; we were constantly removing her pillows; her distress was extreme; Mr. Long called twice in the course of the Monday; the first time was between eight and nine in the morning; I did not then see him with Miss Cashin, but I waited in the drawing-room to ask how she was; he then said that she was doing uncommonly well; Miss Cashin continued during the morning getting gradually worse; in consequence of her condition, Mr. Brodie was sent for; he saw her about six in the evening, and under his directions some things were administered to her; he ordered a poultice and a saline draught, and the deceased was for a time a little better; Mr. Long called about seven o'clock, after Mr. Brodie had seen the patient; Miss Cashin passed a very bad night; I saw her at half-past seven on the Tuesday morning, and gave her a saline draught by Mr. Brodie's prescription; in about half an hour afterwards I gave her a cup of coffee and some dry toast; Mr. Long had not interdicted Miss Cashin from any particular kind of food; he said, in the course of his attendance, that his patients might eat or drink whatever they liked, without restriction; after giving her the coffee and dry toast I quitted her; she was then extremely pale, and looking very ill; some time after the bell rang violently, and there was a great thumping on the floor; I was then at my breakfast; I immediately went up to Miss Cashin's bed-room; I found her dying; I tried to get a teaspoon-full of brandy into her mouth, but her jaws were quite set, and she was dead; she died about ten o'clock in the morning of Tuesday; I believe Mrs. Cashin is now in Ireland.

Mr. GURNEY said that he had no question to put in cross-examination to this witness.

By the COURT. The deceased was the elder Miss Cashin; the other Miss Cashin was a patient of Mr. Long before the deceased came under his hands; the younger Miss Cashin was under his care from the time they first came to lodge at my house; the deceased had become a patient of Mr. Long for four or five days before I went with her to Harley Street.

Mr. Patrick Sweetman examined by Mr. ALLEY. I live in Dublin, and married the sister of the deceased; in consequence of a letter I received I came over to this country; the deceased left Ireland about seven weeks before I came over; she was then in very good health; I arrived in England on the Saturday previous to her death; I went immediately to see her; Mr. Long came to see her soon after I got there; I asked him what he thought of Miss Cashin; he replied that she was doing remarkably well—as well as he could wish; I remembered that her stomach was sick; I was in the hall when Mr. Long came in; I heard Mrs. Roddis ask if something should not be done to allay the heat of Miss Cashin's back; he said it should be exposed to the air; Mrs. Roddis said she thought something ought to be put to it; Mr. Long said, Then if there must be something put, put a little cold cream, and sop it up with linen from time to time; Mrs. Roddis said she could not bear it; he then said, What would you put? She said she had applied a poultice in the morning, which had given relief.

Mr. Justice PARK. Mr. Alley, is it worth while to have this repeated? No earthly witness could have given all this better than the last witness; and she has not even been cross-examined; therefore she cannot need confirmation.

Mr. ALLEY. I am obliged to your Lordship.

Examination continued. I breakfasted with Mr. Long on the Sunday morning. I told him that I had come to inquire concerning the health of Miss Cashin; he said that her friends need be under no apprehension, for her back was in the state that he wished it to be, and there were many of his patients who would be glad to have such a discharge—her stomach, he said, would get well of itself. He told me that a young lady, a patient of his, had asked him what he thought of Miss Cashin, and that he told the young lady, that unless she (Miss Cashin) put herself under his care, she would die of consumption in two or three months; the young lady told Mrs. Cashin the conversation she had had with Mr. Long; the consequence was, that Mrs. Cashin put Miss Cashin under his course of treatment, hoping to prevent her falling into a consumption; he told me that he rubbed a mixture on different parts of the body, sometimes on

the back, sometimes on the chest, the head, or the eyes; he produced a book, and asked me to sign it—it was requiring the subscribers not to divulge what the mixture was, or what was its colour; I said I had no objection; I could not divulge it, for I neither saw it nor knew any thing about it; a gentleman in the room remarked that it was all nonsense; Mrs. Cashin is in Ireland; Miss C. Cashin was 24; Miss Ellen Cashin was about 16 or 17.

Mr. Benjamin Brodie, examined by Mr. C. PHILLIPS. I am a surgeon; I went on Monday, the 16th of August, to the house of Mrs. Roddia, to see Miss Cashin; she was at that time confined to her bed; I was there between five and six in the afternoon; I examined the person of the young lady; I found it extensively inflamed; the whole of the inflamed surface was about the size of a plate; in the centre there was a spot nearly as large as the palm of my hand, which was black, dead—in a state which we call sloughing, or mortification; she was also suffering excessively from incessant sickness; I was informed that nothing whatever would remain on her stomach; I prescribed some medicine for her to take, merely with a view to allay the sickness; nothing further could be done at that time, and a poultice was to be applied to the back; I thought her very ill indeed, though I did not think that she was in that immediate danger which it appeared she was; it appeared to me as if some powerful stimulating liniment had been applied to her back. I called at the house on the following afternoon, and found that she had died in the morning; I should think it was quite absurd to administer a tumbler of mulled port-wine, it could not be expected to stay on her stomach; I should not think it right to apply a stimulating liniment to the back of a person in perfect health to produce such a sore, nor do I think that any of the stimulating liniments in ordinary use would produce the same effects—the same extensive mischief—I mean by that to include both the constitutional effects and the local effects; in my opinion, the sickness and vomiting were as much the effect of what had been done as the mortification.

By Mr. Baron GARROW. I think the application of such a liniment to a person of the deceased's age, sex, and condition, was likely to produce disease and danger; and it has fallen to my lot to see a case similar since this occurrence.

By the COURT. There is great difference in constitutions, and I do not mean to say that it would produce equal danger in all cases; it is the practice of some medical men to apply stimulants to the chests of persons labouring under consumption; I knew nothing of the young lady before the

Monday; wine would have been proper in this case, if the stomach could have borne it, administered in moderate quantities; I was not present at any of the *post-mortem* examinations; but I can say, that what I saw on the back was quite sufficient to account for death.

Dr. Alexander Thomson, examined by Mr. ALLEY. I am a bachelor of medicine; I have heard Mr. Brodie's evidence, and I perfectly agree with his opinion.

Mr. Thomas King, examined by Mr. C. PHILLIPS. I attended the examination of the body of the deceased, at the chapel in Moorfields, on the 24th August; I observed the state of the back; there was a piece of dead, or disorganised skin—such as we call an eschar, and which Mr. Brodie has called a slough—between the shoulders, about the size of my hat; the parts immediately beneath the skin were gorged in a watery fluid, called serum; I examined, in company with Dr. Hogg, Mr. James Johnson, Dr. Maclean, and others, the body, to see if there was any latent disease; we discovered none; the vital parts of the body appeared to me to be in a tolerably healthy state, such as the body of a previously healthy person would have after lying a short time in the earth.

Dr. James Johnson, examined by Mr. ALLEY. There was no other appearance of disease except the wound on the back.

Dr. John Hogg examined by Mr. PHILLIPS. The wound on the back appeared as if produced by gunpowder. The sheath of the spinal marrow was discoloured opposite the external wound, from which he concluded that there had been great constitutional disturbance. The violence done to a delicate and nervous young lady was enough to cause death.

Dr. Goodeve examined by Mr. ALLEY. He would not have inflicted such a wound.

Alice Dyke examined by Mr. C. PHILLIPS. The prisoner is my master; I am now in his service, and have been for six months. I was in his service on the 3d of August; I remember Miss Cashin; on the 3d of August I rubbed some liquid on the back of Miss Cashin, by Mr. Long's orders that was the first day on which I rubbed her back; I never rubbed her except that time; I do not know of what that liquid was composed.

Cross-examined by Mr. GURNEY. Mr. Long had a great many patients, many of them persons of rank and station; I was employed to rub the ladies; I used to take the lady that was to be rubbed behind a screen, separate from the rest, who were in the same room; the rubbing was done for the purpose of producing a discharge; she was rubbed but once, but came day by day afterwards to be dressed; I washed round

the sore on those occasions with a lotion; I rubbed her with the same liquid, and washed her with the same lotion as others.

Cross-examination continued. The rubbing did not produce a greater discharge from Miss Cashin's back than from the back of other patients; I dressed it every day, and it did not put on a more angry appearance than in other cases; the Marchioness of Ormond and Lady Harriet Butler were there the same days as Miss Cashin, and the same lotion was used to Lady Harriet as to Miss Cashin; Mrs. Otley was also there at the same time; the lotion was used with her; Miss Roxburgh was another; the wound was dressed with a cabbage leaf, after it had been washed round with the lotion.

Re-examined. There was only one lotion used altogether; the lotion which I used for the washing was the same as that used to produce the discharge; Miss Cashin's mother and sister were the only other persons in the room when I rubbed Miss Cashin; when all the liquid in the bottle was used it was filled again by Mr. Long; the sore in Miss Cashin's back, on the 14th of August, was not bigger than the palm of my hand, and not a bit worse than that on other ladies; the colour of the sore was rather red.

The case for the prosecution here ended.

Mr. GURNEY submitted that there was no case to go to the Jury; there was no evidence to show that the deceased had been in any respect differently treated from the other patients in attendance upon Mr. Long. He had applied to her the same remedy which he had applied in other cases, and which had been so applied with the most complete success.

Mr. Serjeant ANDREWS followed Mr. Gurney on the same side, pressing upon the attention of the Court the view that Lord Hale and Mr. Justice Blackstone took of cases of medical practice, observing, that however liable formerly to actions, if not regularly licensed, medical practitioners could not be found guilty of manslaughter. The question which he conceived presented itself to the Court, was, whether or not Mr. Long had assiduously used those remedies which his means and education enabled him. If he acted *bond fide*, however mistaken, he could not be held as having committed a criminal act.

Mr. ADOLPHUS followed on the same side.

Mr. Justice PARK said that he had consulted with his learned brother, and found that their views of the case did not coincide upon the whole matter, therefore he should not feel himself justified in stopping the case.

Mr. Baron GARROW observed, that he felt bound to state his impression respecting the present case. It was his opinion that

if, upon the facts of the case, it did turn out that the verdict of the jury was unfavourable to the prisoner, the question of law ought to be submitted to the solemn adjudication of the congregated wisdom of all the judges. At that stage of the trial he would himself recommend that the opinion of the jury be taken upon the question of fact, and leave to the judges at large to decide the question of law. Adverting to the case of Mr. Van Butchell, he observed that Mr. Baron Hullock was perfectly right in stopping the case. There excellent grounds existed for his doing so, which did by no means apply to that then before the jury; and it was further to be remembered, that in Mr. Van Butchell's case no third person was present during the application of the remedies or the performance of the operation. When he considered the several authorities affecting the present question, he must say that there was not the slightest distinction between the conduct of the most eminent physician or surgeon, or the poorest, humblest, and least educated man in the community. No matter whether prejudice, ignorance, or poverty, brought his patients to Mr. Long, he must stand in a court of criminal judicature exactly in the same situation as would the president of the College of Physicians, or the president of the College of Surgeons; the humblest and the highest ought to occupy precisely the same situation; the only question was, whether the prisoner at the bar had used sufficient care and diligence in the application of a remedy which he apparently believed to be efficacious. Were he drunk, or did he do that which on the face of it could not fail to be mischievous, the law would hold him to have acted criminally. But his (Baron Garrow's) reading of the law was, that the humblest bone-setter in the remotest village stood in the same situation, in regard to a criminal prosecution, as if he were the president of the most distinguished college in the United Kingdom. It was in the highest degree important that the law should be settled if any doubt existed on the subject, and so it would be if, upon a consideration of the facts, the jury thought the conduct of Mr. Long culpable.

Mr. Justice PARK then asked the prisoner if he had any-thing to address to the jury. A written defence was put in, which the officer of the court read to the jury. It set forth that the mother of the deceased brought her to him—that a younger sister of Miss Cashin had been labouring under pulmonary consumption—that he administered to the deceased the same remedy that had been found efficacious in other cases—that he had many witnesses in court to prove that he had treated a variety of cases with the most complete success which had

been considered hopeless, and that the unfortunate failure which occasioned the death of Miss Cashin was of a nature by no means unfrequent in the course of medical practice. He complained of the effect produced against him by statements and commentaries made through the medium of the public press, and prayed the jury to discharge from their minds any feelings which such publications might have created.

Witnesses were then called on the prisoner's behalf.

Mr. Samuel Houghton, of Manchester; had consulted Mr. Long as a medical man; had attended him about eight months; was satisfied with his skill and abilities.

Mr. Samuel Wilding, of Shropshire, had once resorted to Mr. Long for the same purpose; was under his care for eleven weeks; was perfectly satisfied with his attention and medical skill.

Miss Harriet Page had been under the care of Mr. Long, and was very much satisfied with his kindness, attention, and skill.

The Marchioness of Ormond, and three of her ladyship's family, had been under the care of Mr. Long, the eldest five months, and the other four; was perfectly satisfied with his attention, humanity, and skill.

Mrs. Sarah Ottley had had occasion to resort to Mr. Long as a medical adviser; was under his care for three months. His attention was such as to perfectly satisfy her.

Miss Penelope Smith had been under the care of Mr. Long for five months up to the present time; was decidedly of a favourable opinion of his skill and humanity.

The Marquess of Sligo, four months under Mr. Long's care, deposed that he never saw nor heard of a medical practitioner more kind-hearted, attentive, or humane.

Lord Viscount Ingestrie had occasion to consult Mr. Long, and was perfectly satisfied with his skill.

Miss Ottley, Miss Sarah Webb, Mrs. Forti, Mrs. Swinden, Colonel Campbell, General Sharpe, M. Prendergast, Esq.; William Addington, Esq., of Kentish Town; the lady of General Ashworth, her sister, and three children; Mrs. Macdougall, of Guernsey; Mr. Pemberton, who produced his child, which had been cured two years since; Mr. John Braithwaite, of the New Road; Miss Anna Grindley; Miss Ann Roxburgh; Mr. George Lyng, of the Borough; Samuel Sotherby, bookseller; Mr. Roxburgh, the father of Miss Roxburgh; Mrs. Prendergast; Mr. William Conway; Francis Roxburgh; Mr. George Manley; were then called. They all expressed themselves perfectly satisfied with the skill, humanity, and kindness evinced towards them by the prisoner.

Mr. Justice PARK then proceeded to sum

up. He requested the Jury to discharge from their minds any-thing they might have heard out of doors on the subject of the accusation under which the gentleman at the bar then stood. No doubt the publications that had appeared respecting it were such as might have the effect of influencing the minds of juries, if they did not labour to free themselves from the prejudice which might so be created—not that he meant to impute to those by whom the public press was conducted, any intention of doing a disservice to Mr. Long; on the contrary, he felt perfectly satisfied that they were men of too much honour and probity to entertain any such intention. He was sure not one of them put forward such publications with the view of running down an individual. The Jury, whom he then addressed, would, he was sure, remember that they were acting under the solemn sanction of an oath, and would feel it their bounden duty not to allow themselves to be influenced one way or the other, but to give a dispassionate consideration to the case brought before them. For himself he knew nothing whatever about the case, except what he had heard that day in Court, and what he had learned from the depositions laid before him. He was, at the time of the inquest, in a distant part of the country—his mind occupied with other matters—and supposing, as he had a right to do, that the case would not come before him, but before those of his learned brethren who had presided at the September Sessions, he had, therefore, not the slightest acquaintance with the case, excepting what was derived from the depositions, and what he had that day heard in Court. He could not let pass that opportunity of saying that he had always thought, ever since he had the power of thinking, that there could not be a more dangerous error than to permit the previous publication of evidence afterwards to come before a jury. It was, in many cases, impossible for the most honest and upright mind to divest itself of prejudice; but were it possible in all cases—and he hoped it was—it would be highly desirable for a jury to divest themselves of every sort of previous knowledge; above all, they were bound to remember that they had nothing whatever to do with the verdict of the coroner's jury or of the grand jury. Doubtless, the matter could not come before them without a verdict of some sort; but it was to be observed, that the evidence upon which the Grand Jury found their bill, was far short of what came before a petit jury for their decision. He could not help saying that he thought it unfortunate the counsel for the prisoner should have sought for an immediate acquittal before the defence was entered on, because it led to an apparent difference of opinion be-

tween him and his learned brother; their difference was not so much as to the law of the case, as with respect to the course which it was then expedient to pursue. He held, and he believed there could be no second opinion amongst lawyers on the subject, that nothing but the grossest ignorance, or the most criminal inattention, could render any man, licensed or unlicensed, amenable for his medical practice to a court of criminal judicature. He then read over his notes to the jury, who immediately retired to consider their verdict.

A little after seven o'clock, Mr. Justice PARK again entered the Court, and ordered the Jury to be called, apparently with an intention, if they had not agreed on their verdict, to apprise them of his wish to retire for the night, and that they must therefore be locked up until Monday morning. The Jury did not immediately obey the summons, but in the course of about five minutes they returned into the box, and were then asked if they had as yet agreed on their verdict?

The Foreman instantly answered yes; and that they found the prisoner—Guilty.

The expression of this opinion, so different from what was anticipated by the audience in Court, from the summing up of the learned Judge, excited very great surprise, and several persons gave utterance very audibly to their feelings of satisfaction.

Mr. Justice PARK promptly reminded them of the necessity of conducting themselves with decorum in a Court of Justice, and his determination to punish those who repeated the offence.

His Lordship, who seemed to be very little prepared for such a verdict, then consulted for a few minutes, in great apparent earnestness, with the Recorder, and immediately afterwards begged the Sheriff to request the attendance of his brother Garrow.

Mr. Baron GARROW, the Sheriffs, and a number of Aldermen and Magistrates, then entered the Court; and a consultation between the two learned Judges and the Recorder was then renewed for several minutes. At its conclusion,

Mr. Justice PARK addressed the Counsel for the prisoner, and observed that under the peculiar circumstances of the case, he and his learned brother had agreed to defer passing judgment on the prisoner until Monday morning.

Mr. Serjeant ANDREWS immediately addressed his Lordship, and requested, in that case, that the prisoner might be permitted to depart, on finding sureties for his re-appearance on Monday morning.

Mr. ALLEY, however, was proceeding to oppose this application on the part of the prosecution, when

Mr. Justice PARK said he could make no distinction between the case of the prisoner

and that of any other person convicted of felony: justice must be dealt out to the same extent to the rich man as to the poor. He begged, however, that he might not, in saying this, be supposed to cast any aspersion on the character of the prisoner, as he had no doubt, if the forms of justice had allowed his taking bail for the prisoner, that he would have appeared accordingly. It was probable that the Court might pronounce a sentence of imprisonment, and consequently it would make little difference whether the judgment was pronounced then or on Monday.

The prisoner was brought in from Newgate on Monday at twelve o'clock (at which time Mr. Justice PARK attended), when he was sentenced to pay a fine to the King of TWO HUNDRED AND FIFTY POUNDS. JOHN LONG immediately pulled a handful of banknotes from his pocket, paid the money to the officer of the court, and was immediately discharged. Having quitted the bar, he proceeded to the court-yard in company with his friends, where he got into the curriole of the Marquis of Sligo, and rode off with his lordship amidst the congratulations of his "noble" friends, and the hootings, hissings, and laughter of the populace.

#### ON THE MODE OF ELECTING HOSPITAL SURGEONS.

*To the Editor of THE LANCET.*

SIR,—Your readers cannot be insensible to the strenuous efforts you have made on several occasions to direct the attention of the profession, and the governors of hospitals in particular, to the abuses exercised in the present system of electing their surgeons. You have proved how often, by interest, an inexperienced youth has been placed over his superiors, and you have deprecated the glaring impropriety of making that the prize of consanguinity which should be the boon of exalted merit, and the reward of indefatigable professional study: although this has become a thrice-told tale, still no remedy has been applied. I therefore trust I shall not be thought presumptuous if I address to hospital surgeons a few remarks which appear to me calculated, in some degree, to ensure to them an increased portion of respect and consideration in the profession of which they are responsible members.

Every hospital, in proportion to the number of surgical patients received into its wards, should maintain one or two house-surgeons to take the immediate charge and superintendence of casualties. The appointment should be given to members of the

College of Surgeons, from 23 to 26 years of age who have conducted themselves irreproachably as students and dressers at the hospital, and who, under a public examination, have given proof of superior attainments in the science, and dexterity and skill in the practice, of surgery. The office should be held one year, and where the services of two house-surgeons are required, it would be a desirable arrangement to make the election half-yearly.

With regard to the appointment of surgeons of hospitals, it should be considered as an indispensable qualification in the candidates to have filled the post of house-surgeon; in fact, the governors should be urged to reject all those who had not taken that probationary step, and not, as at present, fix their exclusive choice on the apprentices of the surgeons.

I am induced to present these suggestions to the consideration of hospital surgeons for many reasons; in the first place, after an absence of some years from the hospital of which I was a pupil, I was sensibly impressed by the increased emulation of its surgeons, I found each courting the remarks and inquiries of the student, and anxious to impart every fact illustrative of the cases presented to view; in short, instead of the taciturn perambulation of ward after ward, to which I had in some measure been accustomed, I found the whole time occupied in an interesting clinical conversation. This improved state of circumstances gives me the conviction, that surgeons of hospitals are awakened to an enlarged view of the important duties connected with their public situations; evincing then as they do, a zeal for the profession, united to the benevolence of the trust reposed in them, we may reasonably hope to gain their concurrence in any measure tending to the general good to elevate their own character as a body. Again, they have great influence in the establishment of which they are officers, and as long as that influence is exerted in a cause which ultimately tends to the amelioration of human misery, it is their just reward, and no disinterested individual of the medical profession would wish for an instant to deprive them of their well-earned prerogative, but this power furnishes us with another claim upon them, for at least a serious consideration of any proposal offered for their approval.

I cannot conclude without making a few general remarks on the favourable results likely to arise from the adoption of the foregoing suggestions. In the first place, the greatest stimulus is afforded to the student, and an excitement is given to excel in hospital pursuits, for he has always before him the prospect of filling a distinguished situation. We have had too many serious instances of

the utter incompetency of dressers not to feel assured, that any measure calculated to mature their knowledge must abound in advantage to the community, inasmuch as the patients committed, in some degree, to their care, would have present and competent aid secured to them in the distress of sickness.

Advancing in our proposition we come to the house-surgeon. This appointment, instead of being *bartered* as it is at present, and made a very expensive undertaking, should be reserved as a reward for the skilful performance of the duties of dresser, and good general conduct in the hospital; but it should be *given* under certain conditions, as, the candidate being perpetual pupil of the hospital, a member of the College of Surgeons, and having undergone a public examination.

We now arrive at the desirable ultimatum at which I am aiming, and I wish fully to establish the position, that all hospital surgeons should be selected by the governors from the *ci-devant* house-surgeons, because then the situation would be filled by men who, through all the gradations of their professional career, have been influenced by the most ardent zeal in the acquisition of knowledge, from the period of their commencing as pupils to the consummation of their highest hopes and wishes in the possession of the honourable distinction of hospital surgeon, a title which would then at once emerge from that baneful cloud (private interest) by which its brightest features are at present obscured, and bursting forth as the reward of genuine merit, and the incentive to high deeds, would become the admiration of men of science as an ornament only to be acquired by character, industry, and professional attainments.

I have the honour to be, Sir,

Your constant reader and well-wisher,

APIS.

COLLEGE OF SURGEONS.

---

*To the Editor of THE LANCET.*

SIR,—I am greatly surprised at Mr. Willcock's misconception of the charter of that high-minded body, the Council of the Royal College of Surgeons. The error should be corrected on account of its tendency, which is to revive a custom that is falling into disuse; I allude to "passing," or, in other words, submitting to be fleeced of twenty guineas, under the false pretence that the diploma is a necessary ingredient in the composition of a surgeon.

The depressed circumstances of many medical pupils made it necessary to economise their funds; and in order thereto,

they naturally inquired what was essentially necessary to the completion of their education and their qualification to practise? THE LANCET soon satisfied them, that to practise surgery, the diploma of the College was not a necessary warrant; and they themselves well knew, that as the college examination was not a test of fitness, so was the certificate no evidence of ability. The diffusion of this knowledge has occasioned a great falling off in the exchequer of Lincoln's Inn Fields, thereby wounding those worthy men, the examiners, in their centre of sensibility—the pocket; and has I believe done more towards producing passing and approaching changes, than even your eloquent denunciations of their iniquitous legislation.

It cannot be too generally known, that the college diploma confers no advantage, that it does not protect the possessor from the rivalry of another who has not been a prey to the spoilers, that it will not enable the holder to enter the public services—in other terms, it is a piece of sealed paper certifying lies, and signed by men whose corporate injustice leaves no doubt of their willingness to sign an instrument which would consign the holder to the prince of the power of the air, for half the “consideration” they extort for the evidence of their cupidity, and the illimitable folly of their dupe—the purchaser.

With unbounded gratitude for your ceaseless and successful endeavours for the interests of your professional brethren, and those of science and humanity,

I remain, Sir,

Yours respectfully,

A SURGEON.

## LONDON HOSPITAL.

*To the Editor of THE LANCET.*

SIR,—Although I cannot approve of the abuse which Mr. W. A. Walford has so indiscriminately and unparingly showered down upon the heads of Sir W. Blizard and Mr. Headington, or help being pleased at the spirit which has actuated the pupils of the London Hospital in taking up the cudgels in defence of their teacher; yet I think they might have spared themselves the trouble, had the former gentleman only been concerned; for they may rely upon it, that there is not one amongst them for whose interest, unconnected with his own, Sir William cares a rush. I know not what the morn of his life was, but I can recollect that the afternoon was rather unpropitious; it was much inclined to be boisterous; but with this curious anomaly, although the wind which was raised, raged

with fury amongst the shrubs and under-shrubs; yet it courteously passed by the stately tree which seemed to mock its rage, without even ruffling a leaf. The eve was rather more calm, but it led to a long and dreary night, which still continues to darken the path of the surgical student, without even an occasional ray to illumine it. From amongst the many illiberal acts of this worthy knight, may be selected the following: his continued hostility to Mr. Headington when a pupil, for daring to amputate an arm, the urgency of the case not admitting delay:

His unjustifiable conduct towards Dr. Frampton (then Mr. Frampton), one of the most talented men who ever sat in the anatomical chair of the London Hospital or of any other school, of whom an eminent surgeon of the present day was heard to say, when his name was spoken of, “Oh! you mean the young man who was so ill used by the Blizards:”

His implacable hatred to Mr. John Scott, his assistant, for presuming to think and to act for himself:

His present hostile feelings, which are displayed against those anatomical pupils who have not yet entered the hospital, in not allowing them the advantage of subscribing to the library, although it is acknowledged that they are in debt to their bookseller between 20*l.* and 30*l.*, which the subscriptions from these young men would soon liquidate; and in obstinately refusing to allow any of these anatomical pupils to witness the performance of an operation. Upon one occasion last winter, I was present at the performance of several operations, when Sir W. cast a look around, and discovering more pupils than usual, he, in a very authoritative tone, desired those gentlemen who were not pupils of the hospital, to leave the theatre. This mandate was, of course, not attended to, and the knight was content to mutter something about “very ungentlemanly conduct.” Upon leaving the hospital, I learned that the anatomical lecture had been put off for that day, in consequence of the number of operations to be performed. These disappointed young gentlemen were expected then to walk quietly back to their homes! “*Pro sancte Jupiter!*!”

Stranger, come not nigh,

He sees a *lancet* in every eye.

Should you deem this letter worthy a place in your useful journal, I shall be obliged by your inserting it.

I am, Sir,

Your most obedient servant,  
A FRIEND TO THE MEDICAL STUDENT.

23, Hadlow Street, Burton Crescent.

P

## THE LANCET.

*London, Saturday, Nov. 6, 1830.*

THE forms of law,—we wish we could say the satisfactory decrees of justice,—having been fulfilled in the case of JOHN LONG, we are relieved from the pain of further silence, and may now give full expression to our feelings of indignation, without the risk of incurring the charge of “desiring to prejudice the public mind against a man who is about to endure the ordeal of a trial before a jury of his countrymen, upon an accusation of felony.”

Before advertng to the recent proceedings at the Old Bailey, it may be necessary to go back to the circumstances of the inquest, and to refer once more to those transactions with which we were so unexpectedly and unwillingly connected. As some few persons have taken upon themselves to condemn the Editor for his interference at the inquest, and as the cause of his presence on that occasion appears still to be ill-understood by a portion of the public, it may be well to re-insert in this place the explanation which was published in No. 366 of THE LANCET: “Late on Friday night, August 20th, two gentlemen called at the residence of Mr. WAKLEY, in Bedford Square, and stated that an inquest was to be held the next day at noon on the body of a young lady who had been under the treatment of Mr. Long; that her life had terminated almost suddenly, and under circumstances which appeared to demand a rigid investigation; that the sister of the deceased young lady, who had also been under Mr. Long’s care, was in a dying state, and only expected to survive a few hours; that the family was from the sister kingdom, and that the mother and brother-in-law were entire strangers to London, were suffering the most intense anguish, were half distracted, and knew not what course to adopt; that

the brother-in-law, Mr. Sweetman, had been strongly urged to request Mr. Wakley to attend at the inquest and act for the family, in order that the ends of public justice might not be defeated. In compliance with the wishes of the relatives, the two gentlemen observed they had then called. Mr. WAKLEY pointed out to them, that his appearance on the inquest at that time, as he was a candidate for the office of Coroner, might to many persons appear very objectionable, and in the absence of explanation, would indicate very bad taste, if not defective judgment. Moreover, he represented to them, that having long ago denounced Mr. Long as a quack and an “impostor,” his attending, as it were against Mr. Long, might assume the character of vindictiveness. He therefore refused, in the most positive manner, to take any part in the proceedings, unless he received, on the following morning from the deceased young lady’s relatives, an especial request for his interference. Early the next day, a gentleman called from Mr. SWEETMAN, and solicited, as a particular favour, that Mr. WAKLEY would call upon the relatives before the time appointed for holding the inquest. Accordingly, about half an hour previous to the arrival of the Coroner, Mr. WAKLEY attended in Mornington Place, and after a very few words had passed, he found that he could not, consistently with what he deemed to be his public duty, any longer withhold his consent to appear at the inquest, on behalf of Mr. SWEETMAN, and the deceased young lady’s distracted parent.

“Of course Mr. WAKLEY acted without fee or reward, and solely upon public grounds. If any one condemn his conduct, that person can neither be a kind parent nor an affectionate brother; neither can he be possessed of those feelings which should direct the conduct of an honest man.”\*

The proceedings at the inquest held on the body of the unfortunate Miss CASHIN were

---

\* LANCET, September 4th.

chiefly remarkable for having exhibited the medical and *legal* incompetency of an attorney-coroner; the extreme ignorance of a bullying barrister named ADOLPHUS; the clear, scientific, and conclusive evidence given by the well-educated medical witnesses; the delusive, nonsensical, incomprehensible tales related by the Quack's "well-educated" and fashionable dupes; and the patience, clear perception, and strong judgment, which can be exercised by a jury of honest Englishmen. The coroner himself, probably, showed more of the quality of patience than was ever before displayed by human being while in the execution of the duties of such an office. The stuff, the horribly disgusting stuff, to which he listened day after day, apparently without vexation or fatigue, had well nigh smothered all the well-informed portion of the audience,—trash, which was as irrelevant to the subject under inquiry, as it was disgraceful to the insane, or insane, creatures by whom it was uttered. The following may be taken as specimens. A young lady declared that "she had been cured of *consumption* by having been rubbed with Mr. LONG's "liquid." That her "consumption" consisted of a *cough*, which had continued two or three months before she had been "rubbed;" that to cure this "consumption" she had only previously consulted a medical practitioner two or three times; that when "rubbed" the liquid produced no effect upon the skin, except over the part where "her lungs were diseased;" that *there* it instantly produced a wound and a *discharge*; that, under the application of the *same* liquid, the wound healed, when, she being well, the fluid might be rubbed all over her with impunity, as it produced no effect when persons were in health, but that, when rubbed upon skin which covers a diseased part, it would immediately produce a wound and a discharge!"

The *truth* of these statements, it must be remembered, was attested by the concurring

evidence of several witnesses. One gentleman had "inhaled" and "rubbed" for the *gout*, with attacks of which disease he had been troubled for several years, at intervals varying from "one to three months." He considered that he was cured, having had no return of his complaint for about "five weeks!" Another had been much harassed by severe headaches at intervals; the liquid was rubbed upon his chest and produced no effect, but when applied between the shoulders, the floodgates of the peccant humour were instantly opened, and the malady quickly flowed off in the form of a fine limpid stream! Another gentleman bore testimony to the fact that LONG's liquid had completely reduced a decided dislocation of his child's hip-joint! This gentleman was a colonel in the army, and he alleged that, in addition to his own personal knowledge of the fact, he had the authority of several highly-eminant surgeons for saying, that his child's hip had been dislocated. But the all-powerful liquid quickly sent back the refractory bone to its legitimate home! The Marchioness of ORMOND *knew* that Miss CASHIN's back was rubbed with the same liquid that she and her daughters had repeatedly used for washing their hands, but she did not *see* her back rubbed. She "*knew*" it was the *same* liquid because it was taken from the *same* bottle, but she did not "*see*" it taken from the bottle, neither did she "*see*" the back rubbed. Sir FRANCIS BURDETT\* bore testimony to the perfect safety of LONG's practice. The honourable baronet,

\* The motive which induced Sir FRANCIS BURDETT to first visit LONG, has been thus explained. The noble baronet is on terms of intimacy with the Marquis of ANGLESEA, who left the plains of Waterloo, minus a leg. Sir FRANCIS, keenly feeling for his friend's misfortune, having heard of the miraculous powers of the mystic "liquid," and having read probably that if the claw of a lobster be taken off, the energies of the animal are equal to the production of another claw, he applied, it is said, to LONG to know whether, if the "secret fluid" were gently "rubbed" over the skin of the stump, the Marquis's leg and foot might not grow again? It is reported, that although the leg and foot were not forthcoming, the operation was not entirely unproductive, having, within a short period, produced a great toe.

however, "knew nothing of the composition of the liquid, nor of the inhaled gas; nor had he ever seen Miss CASHIN, nor could he distinguish a glass of prussic acid from a glass of spring water."

Such was the nonsense to which the coroner lent a ready ear during several days, although, under the circumstances, it was an insult to the jury, and to the public, to attend to such witnesses, still less to the conceptions with which they had been inspired by their well-skilled juggler. The conduct of the coroner will demand a few more words presently.

Of Mr. ADOLPHUS it is almost unnecessary for us to speak. He is really a poor thing—a very ignorant creature. With all the malignity of the viper, but without the sting even of a gnat, his powerless, ill-directed, and ill-tempered movements, were incessant sources of mirth. It was fortunate for the ends of public justice that LONG had such an advocate. Concerning the *law* of the case, the Coroner and ADOLPHUS appeared to about equal advantage, both having contended, before the inquest terminated, that it was not a case of manslaughter.

The evidence of the medical witnesses, with only one exception, was given with extreme accuracy, precision, and clearness. The exception to this otherwise unqualified approbation, is to be found in the evidence of Mr. BRODIE. As the defect, however, to which we refer, was again prominently observable on the trial, where it might have proved entirely fatal to the cause of justice and humanity, we shall not further advert to it in this place, but notice it while speaking of the proceedings at the Old Bailey.

The jury, until towards the conclusion of the inquiry, listened with the most exemplary attention to a mass of evidence that was not in the slightest degree either directly or indirectly relevant to the subject under inquiry, which, in fact, was to investigate the causes that led to the death of

Miss CASHIN. Had it not been for the extraordinary address of the Coroner at the conclusion, the jury probably would not have deliberated for more than five minutes upon what should be their verdict. The Coroner did not confine himself to the facts elicited in the evidence, but went directly to the *consequences* of a verdict of manslaughter. He not only gave the jury to understand that LONG had not committed manslaughter, but that no indictment for manslaughter could be sustained against any man in such a case, whether a regular or irregular practitioner. The experience of Mr. STIRLING ought to have told him, that to make allusion to the *effects* of a verdict, was proceeding far beyond the line of his duty. It was, indeed, natural enough that the jury should hesitate, when they were given to understand, that a verdict of manslaughter would only cause the culprit to be bailed with reference to his appearance at the Old Bailey. Mr. STIRLING's opinion was so strong on this point, that instead of causing LONG to be apprehended, as was his duty, he kept the warrant for his caption, in his pocket, during several days, and, in truth, until after an application had been made to the magistrates at Bow Street for inquiring into the inexplicable circumstances of the delay. Our view of the case was entirely opposed to that of Mr. STIRLING, and, had we not been fully and firmly persuaded from the first, that it was not only a case of felony, but an aggravated case of felony, far different, we believe, would have been the salutary impression made upon the public mind.

Strongly influenced by this opinion, we pressed for an examination of the body on the first day of the inquest, although this proceeding was much opposed by Mr. SWEETMAN. It is quite certain that we could have had no desire to add torture to the distracted feelings of a family so greatly afflicted; but the omission of the dissection must have produced a mesh in the web of

the law, through which a larger culprit than JOHN LONG might have easily crept; for no medical man could have been justified (although the irritation caused by such a wound as was observed on the back would have been sufficient to kill ten strong persons) in swearing that that wound had caused death, until he had thoroughly examined the internal structures of the body. We therefore urged both the first and the second examinations, by means of which evidence of the most conclusive character was obtained.

After the coroner's jury had returned their verdict of "manslaughter" against LONG, we hoped and expected that there would have been no necessity for further interference on our part. Unhappily we were deceived, for Mr. SWEETMAN declined to appear as prosecutor, or to incur any expense in the affair. Hence Mr. CAPES, the parish beadle, was set down as prosecutor, and the names of the whole of Mr. LONG's witnesses were inserted upon the back of the bill to be preferred before the grand jury. This bill was to have been laid before the grand jury at the Sessions House, Clerkenwell, on Friday, September 17th, the eighth day of the contested election for coroner, when, from the bustle, confusion, and anxiety that prevailed, JOHN LONG entertained strong hopes, probably, that the bill as then drawn up, with the names of the whole of his witnesses distinctly inscribed upon it, would be at once ignored. On stepping from the hustings into the Sessions House, we were much surprised at seeing several of Mr. LONG's "noble" witnesses in attendance, and still more surprised at hearing that they were *all* in the neighbourhood, comfortably lodged in apartments which had been procured for them by the beadle, whose name was set down as the *prosecutor*. Of course we at once saw that a bill, with such a list of names at the back of it, could not be safely preferred before the grand jury. Further, Mrs. ROD-

DIS, from indisposition, was not in attendance. Under these circumstances, we felt little hesitation in applying to the court for a postponement until the next sessions. But it was urged to us by a gentleman of considerable legal knowledge, in the presence of Dr. JAMES JOHNSON, Mr. KING, Mr. EVANS, Dr. HOGG, and other medical gentlemen, that there would be no use in delay; that one indictment was as good as another; that the grand jury would not find "any bill," and that the charge could not be sustained at the Old Bailey, because it was not a case of *manslaughter*. Acting, however, upon the opinion which we had all along entertained, and our views having been supported by the gentlemen just named, we resolved, if possible, not to give such a culprit as JOHN LONG the benefit of an ignored bill. Most of our readers are probably aware, that had not the bill been "found," LONG would have been tried at the Old Bailey on the coroner's Inquisition, but the fact of a bill not having been sustained before the grand jury upon supposed *ex parte* proof, might, in the subsequent proceedings, have acted as a stumbling-block in the path of justice; for it would naturally have been said, how weak must be the charge against LONG, if it could not be supported upon an *ex parte* statement before the grand jury. *Ex parte*, indeed! with the names of the whole of Mr. LONG's "noble" and ignoble witnesses, flourishing in a style of unusual grandeur upon the back of the bill!

A brief reflection on what we had observed at the Sessions House, convinced us that a new bill of indictment was necessary; that the names, which had been improperly inscribed, should not be again inserted; and that the employment of counsel would be indispensable. Accordingly we applied to Mr. HENSON, of Bouverie Street, a gentleman quite unknown to us, but who, we were given to understand, was deeply conversant in the various proceedings of our criminal courts.

The redrawn bill, when laid before the grand jury, was "found," after the examination of only three or four witnesses; and in despite of all the wise and learned predictions to the contrary, in despite of the profound legal knowledge of the attorney-coroner, in despite of the ravings of the gentlemanly and learned ADOLPHUS, LONG has been tried at the Old Bailey, and by another sensible, upright jury of his countrymen, he has been found guilty of *manslaughter*.

The counsel for the prosecution conducted their case with nice tact, and discriminating ingenuity; and the opening address of Mr. ALLEY exhibited a masculine and luminous view of the facts, and of the law. Both Mr. ALLEY and Mr. PHILLIPS, as soon as they had read their briefs, entertained not the slightest doubt that the crime of which LONG had been guilty, amounted to manslaughter; and that in the absence of technical errors, a verdict of "guilty" was certain.

The public will not be a little surprised to learn, that in conducting a prosecution of this important and singular nature, the funds have been supplied exclusively by ourselves, and that we stand responsible to Mr. HENSON for whatever costs may yet remain unpaid. We should not, probably, have alluded to this circumstance, if it were not to stimulate the law commissioners to activity in an important part of their duty; and to show that a *prosecutor* may suffer nearly as great a pecuniary loss in obtaining the verdict of a jury against a *felon*, as the *felon* himself may incur from the sentence of a judge!

Want of space obliges us to postpone the further consideration of this subject until next week.

*The Edinburgh Dispensatory.* Twelfth Edition. By ANDREW DUNCAN, M.D., Prof. Mat. Med. in the Univ. of Edin., &c. Edinburgh: Black. 1830. 8vo. pp. 1127.

Of this elaborate and admirable work, it would be superfluous for us to offer any lengthened notice. The great and gradually-increasing merits of the several previous editions are already known to every well-educated practitioner; while, of the probable value of the improvements in the present edition, Dr. Duncan's characteristic industry, and eminent professional attainments, together constitute an adequate guarantee.

The principal additions in the impression now before us, consist in the introduction of the several improvements of the new Dublin Pharmacopœia, of the important facts and explanations appended to a translation of the Dispensatory by MM. Chereau and Robiquet, and of various tables of classification of the *materia medica*, on natural and physiological foundations. Dr. Duncan has also, at length, remedied an important defect in the previous editions, by adding to the notice of each article in the *materia medica* a list of synonyms, official preparations, and incompatible substances. He has also, following the model of the best continental writers, prefixed to the history of each plant as much of its botanical description as relates to its medicinal employment. Finally, we cannot pass over the highly important additions he has made to our knowledge of the effects of reagents on vegetable solutions.

We have, notwithstanding, caught one little error in the pursuit of our critical angling. In the article on copper, p. 418, Dr. Duncan continues to recommend sugar as an antidote to poisoning by that metal, apparently not aware that it has been proved that the stomach must attain the temperature of 212 before the slightest decomposition of the poison can be accomplished. This fact Orfila has stated in the last edition of his Toxicology, and he at the same time adduces abundant proof of the efficacy of albumen and the ferrocyanate of potash, as antidotes in cases of poisoning by any of the soluble cupreous preparations.

We are almost inclined to indulge in a hearty

laugh at the dismay this edition must occasion among the rising generation of "Athenian" physicians; indeed we take this early notice of the work, for the purpose of calling attention to the great mass of professional information the benevolent professor has accumulated for their edification. In the next number, we shall, perhaps, invoke their approbation of the new edition of Dr. Turner's Chemistry, which, amongst an infinite variety of novel and useful additions, contains highly-interesting details on the "haloid" salts of Berzelius, on charbazotic and aspartic acids, on indigo brown, indigo red, and indigo blue, and on many other equally important subjects.

---

*Medico-Chirurgical Transactions.* Vol. XVI. Part 1. London: Longman. 8vo. 1830.

THIS volume, though not of great bulk, contains a considerable number of papers, of each of which we shall give a short analysis, varying however in length, according to the value and importance of each.

The first paper contains an account of the case in which the aorta was tied in July, 1829, for aneurism of the external iliac, by Mr. James of Exeter, which we have already mentioned more than once. The patient, *ætat.* 44, had been ill four months, his complaint had been considered as 'disease of the hip-joint, and was, for a short time, treated as such by Mr. James, there being many of the symptoms of that disease, and little or no external tumour, at the time of his admission into the hospital. On June 2d, the aneurismal swelling being then greatly increased, so as to occupy the whole of the left iliac region, and considerably protrude the lower part of the abdomen, Mr. James performed Wardrop's operation, the artery being tied about half an inch below Poupart's ligament. During the two days following this operation, there was a decided diminution in the tumour; but, on the third, it began slowly to increase again, and in another week had regained its former size. After this time it extended rapidly in every direction, particularly at its lower and outer part, where the integuments became of a dusky red, and it was evident that slough-

ing would soon take place there. Under these circumstances Mr. James resolved upon tying the aorta, notwithstanding the objections of his colleagues, who all saw the hopelessness of the case. It is unnecessary for us to describe the steps of this operation, which was performed on July 5th, as it differed in no essential point from that of Sir A. Cooper, the operator not venturing to attempt the lateral operation from the fear of peritoneal adhesions, which was subsequently proved to be well founded. Suffice it to say, that notwithstanding considerable difficulty from the protrusion of inflated intestines, and the density of the investments of the artery, the ligature was exactly placed round it, and firmly drawn, entirely putting a stop to the pulsation in the aneurismal sac, and that the patient died three hours and a half afterwards. On dissection, the ligature was found to have been completely applied about five lines below the origin of the inferior mesenteric artery, and to have included no other part except a small vein which lay close upon the aorta. The cause of the failure of the first operation was now discovered,—the femoral, or rather external iliac, artery, dividing just above Poupart's ligament, so that there had remained a free outlet from the lower part of the sac by means of the profunda. The sac itself was of such size and extent, that any attempt to tie the common iliac would have certainly failed, unless indeed it had been made at a much earlier period.

As far as the mere performance of the operation goes, Mr. James is certainly entitled to praise; but we think that he would have shown more judgment had he abstained from a proceeding which could not in this instance, and, in our opinion, never can be expected to, prove successful, since no surgeon will venture to have recourse to it but under the most unfavourable and desperate circumstances, and when all other remedies have failed.

The paper, No. 2, is by Mr. Barlow of Blackburn, and contains an account of the successful removal of a large tumour of the nature of "medullary sarcoma," which had existed for nine years, and occupied nearly the whole cheek, protruding the mucous membrane of the mouth inwards, and depending some way beyond the edge of the lower jaw. The operation had been pro-

nounced impracticable by several surgeons, and is highly creditable to the skill and boldness of Mr. Blackburn; though attended with profuse hæmorrhage, it was accomplished without much difficulty; neither the mucous membrane of the mouth nor the parotid duct was injured, and the patient, a female *ætat.* 41, was, in three weeks, completely recovered. Annexed to this case is another, which occurred more than thirty years ago, in which sudden death was caused by the entrance of air into a vein during the removal of a tumour from the neck. The circumstances of this case agree entirely with those of the case described by M. Dupuytren in 1828, on reading which, Mr. Blackburn became first aware of its real nature, having previously ascribed the fatal event to ordinary syncope from fright or nervous shock.

No. 3 is a case of ununited fracture of the thigh-bone, by Dr. Somme of Antwerp. The patient was a healthy subject, the want of union had been caused by his restlessness, and after five months had elapsed, a complete cure was effected by a new method of treatment, analogous to, though, in some respects, different from, that by seton. As the account of the operation is very short, we shall give it in the author's words:—

"The patient being placed on his back and supported, I passed a long trocar and canula at first downwards on the inside of the upper fragment, and made it pierce the skin behind, and a little to the outside; the trocar was then withdrawn, and a silver wire passed through the canula, and out at the posterior opening. The canula was then withdrawn, and being replaced on the trocar, they were introduced again above and on the outside of the lower fragment, and made to pass out at the same opening behind. The trocar having been removed, the other end of the wire was passed through the canula, so that both ends were in contact behind, leaving a loop in front. I then made an incision in front, from one orifice to the other made by the trocar, and drawing the extremities of the wire through the wound, brought the loop between the fractured ends of the bone, and approximated the edges of the skin with sticking-plaster."

The limb was, after this, carefully confined in a fracture-box constructed for the purpose, and at each dressing the wire was drawn down, so as to "depress the loop more and more into the flesh;" but in six

weeks after the operation, and before it had quite divided the parts which it encircled, it was withdrawn, the ends of the bone being then completely consolidated. To prevent all risk, the use of the apparatus was continued for six weeks longer. The union is now complete, and what is very remarkable, there is not the least shortening of the limb. It is impossible to form any positive conclusion from a single case; but the method in question certainly appears to possess some advantages over the introduction of a seton, the failure of which has, probably, in general been owing to its operation not being sufficiently extended.

No. 4 is an "account of a concrete oil existing as a constituent principle of healthy blood," by Dr. B. G. Babington. This oil, which was first suspected in milky serum by Hewson, lately demonstrated by Dr. Traill, and very recently obtained in a separate state by Dr. Christison, has now been shown by Dr. Babington to exist constantly in the healthy blood not only of man, but of other animals. It may be procured by very gently agitating a quantity of serum with a third part of ether, and separating and evaporating the latter after four or five days, and when it has become of a yellow colour. The oil thus obtained (which forms about  $\frac{1}{1000}$  of the serum of the blood), "is of a deep yellow hue, is semi-solid, and melts at a temperature of 90° Fabr. The specific gravity is .918. From its solution in ether it crystallizes, by very slow evaporation, at a low temperature, in radiated tufts. It burns with a brilliant light, has a faint and peculiar odour, resembling that of a wet bladder, and in its general characters resembles other animal oils. It is uniform in colour, in general appearance, and in all its properties, from whatever kind of serum obtained."

An important fact is thus established, which will probably serve to explain several pathological phenomena hitherto developed in obscurity, and which, therefore, well deserves the attention of the physiologist and the practitioner.

No. 5 is a case of phlegmasia dolens, by Mr. Lawrence. The patient, *ætat.* 40, was admitted into St. Bartholomew's Hospital, for carcinomatous ulceration which had destroyed the whole of the os and cervix uteri. A few days after her admission, she was

attacked with increased uneasiness in the hypogastric region, attended with some febrile excitement, and with swelling of the whole right lower extremity, the temperature of which was increased, but the colour unaltered. The thigh was tolerably firm; the lower part of the leg and the foot pitted on pressure. There was pain in the course of the femoral and iliac vessels, and the internal saphena vein could be traced at the upper part of the thigh by a hardened knotty feel. Mr. Lawrence therefore considered the disease to be essentially the same as the phlegmasia dolens occurring in women recently delivered, and as it was pretty evident that the large veins of the thigh were inflamed, the treatment was principally directed to them. Considerable relief was afforded by the application of leeches along the course of the femoral vein, both on this occasion and when the pain returned a few days afterwards. The swelling of the thigh, the pain and tenderness of the abdomen, diminished, and the patient was gradually improving with regard to this affection, when she died suddenly from violent uterine hæmorrhage. On dissection it was found, that

“The cellular and adipose tissue round the lower part of the uterus and neighbouring portion of the vagina were thickened and indurated, particularly on the right side. The hypogastric vein involved in this diseased mass, was closed in consequence of previous inflammation of its coats; and the same change had occurred in the internal iliac, the common iliac, the external iliac, the femoral and profunda veins, as well as in the internal saphena, all of which were completely impervious. The affection terminated above at the junction of the common iliac vein with that of the opposite side, the latter vessel and the inferior cava being quite natural. The saphena was closed for a length of about four or five inches, beyond which it was natural. The profunda was cut through near the femoral vein, and the latter was divided as it passes the tendon of the triceps. The disease extended in both these vessels beyond the situations where they had been divided, but its inferior limits were not ascertained; the right spermatic vein was closed in its lower half. The coats of the affected vessels and the surrounding cellular substance, were a little thickened, and their cavities were plugged by a closely adherent and tolerably firm substance of a light-brown colour. At some parts the vessels and their contents were of a dark livid hue.”

There can hardly be a doubt, but that the inflammation here, was excited by the carcinomatous disease, and beginning in the uterine veins, extended to the common iliac, and thence to the external iliac and its branches; the case strongly confirms Dr. Lee's view of the nature of phlegmasia dolens, which is still further supported by the two cases described in the following paper by Mr. Holberton. Both patients died of tubercular phthisis, and the affection of the extremity occurred but a few weeks before their deaths. The symptoms in the first case (that of a lad *ætat.* 17) were essentially the same as those observed in Mr. Lawrence's patient. In the second (that of a woman *ætat.* 35), the swelling was softer, came on more gradually, and was attended with less heat. The morbid appearances on dissection were nearly the same in both, and the probable cause of the venous inflammation was an ulcerated state of the colon and rectum. Mr. Holberton is, however, doubtful on this point, since no diseased veins could be traced from the intestine, and the branches of the internal iliac vein were less affected than those of the external.

No. 7 is “a case of stammering, successfully treated by the long-continued use of cathartics,” by Dr. Bostock. The defect of speech came on suddenly, and to a great degree, when the patient was about three years old. Two physicians, who were consulted, were unable to propose any specific plan of treatment, but in consequence of the plethoric state of the child; prescribed a strong purgative. The effect of this was so favourable, that it was repeated several times, and always with decided benefit. In addition to the occasional use of purgatives, a sparing vegetable diet was now recommended, and,

“By a steady adherence to this discipline for about eight years, the complaint was kept at bay, but whenever any relaxation in the diet took place, or when the purgatives were omitted or too long delayed, symptoms of the impediment immediately appeared. At length, when about twelve years of age, the tendency seemed so far subdued, that a relaxation of the restrictions was not followed by the usual unfavourable consequences; and the boy being then at a public school, it was not so easy to maintain the former discipline. For some time no bad effects ensued, but at length the complaint recurred, and was unusually obstinate,

so as to require a long and severe course of purgatives, which was, however, finally successful. During the last two years, the tendency has occasionally manifested itself, but it has always been easily removed by a moderate use of purgatives, and by a temperate, though not a rigidly abstemious diet. The boy, who is now in his fifteenth year, may be said to be free from the complaint."

Dr. Bostock does not of course draw any positive inference from a single case; he seems, however, to think, that the treatment in question might be of service in most instances of stammering, and certainly, considering the analogy which this complaint bears to chorea, it is well worth a trial, wherever the health of the patient offers no obstacle to its employment.

The 8th paper on the pathology of hooping-cough, by Dr. Alderson, does not appear to throw much light upon the nature of that disease; indeed all that can be learnt from it is, that in fatal cases death is generally caused by lobular hepatization of the lungs, and obstruction of the smaller bronchiæ by tenacious mucus, and that the inflammation is confined to the substance of the lungs, and does not extend to the pleura, facts which have been already published by several authors of repute, and which, at least the two former, are now pretty generally known.

[To be continued.]

## LONDON MEDICAL SOCIETY.

November 1, 1830.

MR. CALLAWAY in the Chair.

### PUERPERAL FEVER.

A LONG discussion, chiefly in explanation of remarks made on the last evening, which we did not think it necessary then to report, and need not now therefore give, preceded the immediate subject of debate on the present occasion—the treatment of puerperal fever. With the exception of Dr. Ryan, and perhaps of Mr. Callaway, the speakers were too exclusively occupied in the construction of theories (some of which, from their nature, are utterly unsusceptible of demonstration). We subjoin an abstract of M. Tonnelle's cases, and we would recommend the leaders in the debate to ponder on these facts before they renew the discussion.

### M. Tonnelle's Cases of Puerperal Fever, 238.

Simple inflammation of uterus and uterine appendages .....	79
Inflammation of veins and lymphatics of uterus and uterine appendages ..	110
Inflammation and putrescence of uterus	49

258

At the conclusion of some prefatory observations, Dr. Whiting said, that another case illustrating his views, had occurred in his practice since the preceding meeting, the particulars of which the registrar should read on the present occasion. It was that of a woman, *ætat.* 37, who, 53 hours after delivery, was attacked with rigours, succeeded by abdominal tenderness, uterine swelling, and painful micturition; her bowels were confined; pulse 102; lochia slightly diminished, but no factor described. She was immediately bled, and a course of calomel and opium commenced. It is unnecessary to pursue the detail of the treatment, but she is at present convalescent, after losing altogether  $42\frac{3}{4}$  blood, having had 60 leeches applied, and having taken 30 grs. opium, 40 grs. calomel, and 6 grs. tartar emetic. The mouth was slightly affected.

Mr. Doubleday and Mr. Hoddart had attended this case with Dr. Whiting, who now requested Mr. Doubleday to give the meeting his unbiassed opinion of its nature.

Mr. DOUBLEDAY admitted he should consider it a case of puerperal peritonitis, not of puerperal fever; amongst other features, he thought that the period of the fatal termination formed an important distinguishing feature between the two diseases.

Mr. CALLAWAY begged that gentlemen would be more precise in their terms; one spoke of puerperal fever, one of puerperal peritonitis, and not unfrequently both were confounded together; if such confusion of nomenclature prevailed, it was clear the society could come to no satisfactory understanding on the subject. He would take the liberty of asking Mr. Doubleday if he had ever seen the malignant puerperal fever terminate in peritonitis; and did he think that the case just related would, if neglected, have terminated within an early period of time?

Mr. DOUBLEDAY believed it did sometimes terminate in peritonitis; and with reference to the second question, he dwelt on the favourable influence of the treatment adopted. In this case he considered it important to notice, that the rigours took place 53 hours after delivery; unfortunately, within the last ten days, he had lost a patient in whom the rigours supervened within twenty hours after delivery; in the present instance he thought this a favour-

able circumstance. As to its treatment, there was, in the first place, a pulse of power and exquisite abdominal tendency, so, as he believed, a second opinion could not be held as to the propriety of the mode he had adopted. Although he was not fully a disciple of Dr. Whiting's, yet he considered there was something tangible in his views; but in one point he could not coincide with them at all. He believed Dr. Whiting had said, that the disease could not be knocked down by large bleedings. Now he (Mr. Doubleday) had seen much of puerperal fever, and he had decidedly known it to be cut short by venesection. In the present case he considered the calomel had much to do with saving the patient. Dr. Blundell, too, at present confided in mercury as the principal remedy. He, Mr. Doubleday, usually prescribed it in comparatively large doses; in one case he had given four grains, with one of opium, every other hour. Under such treatment as this, the amendment was usually visible from the first in favourable cases. In conclusion he remarked, that he could not agree at all with Dr. Whiting in the opinion, that the disease might wear itself out. On the contrary he was convinced, that if the pulse remained at 130 for twenty-four hours, even the most powerful remedies would produce but little effect in arresting its subsequent course.

Mr. STEVENS said, that the pathology of disease was so intimately connected with its appropriate treatment, that he should be obliged to depart a little from the regular line of the evening's discussion. Dr. Whiting's opinion of the erysipelatous nature of the disease, he did not think at all strengthened by the present case; he (Mr. Stevens) thought that all the opposing theories on this subject might be readily reconciled with each other, and referred to one and the same disease, without subdividing it into various shapes to suit the several theories proposed. If three physicians were sent to investigate intermittent fever (supposing it an unknown disease), and that one saw the hot, another the cold, and a third the sweating stage, each would form a different idea, yet eventually a better knowledge of the subject would reconcile the conflicting opinions. Thus it was, he thought, in puerperal fever. In its worst forms it had been stated by some that inflammation does not take place, and this may be fairly admitted, unless it be denied that destruction of tissue may take place independently of inflammatory action. If it would be believed that some noxious agent might produce these changes without inflammation, he believed every difference might be reconciled. He had himself formed peculiar views on the subject; he believed the diseased agent to

be the blood; he considered that the blood of the uterus was corrupted, robbed of its vitality, and rendered unfit for the uses of the system. The disorganisations of the liver and lungs which are found in this disease, could thus be satisfactorily accounted for; both the malignant form and the inflammatory he considered could thus be explained; thus a minor degree of the depravation would only affect the uterus, while the greater would involve the entire system. There were numerous analogous examples of similar agents producing in different degrees the most opposite conditions; thus alcohol or opium in a small quantity excited, and in a larger narcotized the system. On this hypothesis the lochial suppression and fetid secretions would also tend to elucidate the subject, and might be viewed as malaria, or noxious agents influencing the uterine blood. In support of this opinion he cited a case in which he had known puerperal fever to supervene on the suppression of a profuse vaginal discharge, and he had seen several cases of sporadic inflammation originating apparently in the same manner.

Dr. RYAN felt quite surprised, that in the discussions on this important subject, so much had been said of the opinions of older writers, while the more accurate and well-founded views of the most recent authors had not been alluded to at all. This year there had been published an account of 220 cases of the *malignant fever*, not of peritonitis, in the great majority of which it was found that the uterine veins were inflamed. In the German epidemic of 1819, this pathological fact had been noticed; in the last number of the Edinburgh Medical Journal, and in that with which he was connected, there were critical notices of the recent work of M. Tonnelle, in which numerous examples were described of the inflammation of the uterine veins, especially those to which the placenta had been attached, abscesses had also formed in other parts. The disease might decidedly occur before delivery. In the great majority of cases the lochia were fetid. Dr. Blicke had, in the early part of the evening, mentioned this as an undescribed symptom. Now, it was very well known that Dr. Hamilton, of Edinburgh, laid especial weight on this point in his lectures. Dr. Ryan briefly enumerated the principal modes of treatment, namely, by turpentine, depletion, and calomel and opium, and to a combination of the two last, seemed to give the preference.

Dr. WHITING begged Dr. Ryan to state whether he believed that common puerperal peritonitis could continue longer than ten days.

Dr. RYAN. Decidedly it could, and by merging into the chronic state, could even continue for forty; puerperal fever and

puerperal peritonitis were two distinct and separate affections; and if the continental writers were correct, which he (Dr. Ryan) believed them to be, the name of uterine phlebitis might be substituted for the former appellation of this disease.

Dr. BLICKS said, that in one case out of 100, he thought no treatment necessary beyond warm fomentations and opiate clysters, and certainly it would be rather too much.

## WESTMINSTER MEDICAL SOCIETY.

*Saturday, 30th October.*

Mr. BACOT in the Chair.

Dr. A. THOMSON read a voluminous paper containing an account of the progress of a supposed case of hydrophobia, and the morbid appearances found on dissection.

Considerable doubt was expressed by some of the members, especially Dr. GRANVILLE, as to the hydrophobic character of the affection. In this opinion he was joined by Dr. BARRY, who considered the symptoms rather of the tetanic kind; trismus and opisthotonos were certainly very decidedly noticed, and the morbid sensibility to atmospheric exposure was entirely wanting.

Some doubt was even expressed as to the existence of such a disease as hydrophobia, communicable by specific contagion; in reply to which reference was made to the propagation of the disease by inoculation, as proved by the experiments of Mr. Youatt.

The *treatment* of hydrophobia was but very superficially alluded to. Dr. BARRY, in reply to a question as to his opinion of the utility of applying cupping-glasses to the recent wound, related some experiments made on pigeons poisoned by the bite of the viper. In one of these death took place in five minutes where the glasses had not been applied, but where they had been used, no bad symptoms ensued.

Dr. GRANVILLE announced his intention of reading a paper at the next meeting but one, on the political condition of midwifery in the metropolis.

## STATISTICAL REPORT ON THE ASYLUM AT CHARENTON.

M. ESQUIROL, the medical superintendent of this hospital, has lately published in the "*Annales d'Hygiène Publique*," an interesting paper on the state of the lunatic asylum at Charenton, and the statistics of insanity in general. The following is a short extract:—

In 1826, 1827, and 1828, during the months of June, July, and August, the proportionally largest number of insane persons was admitted, an observation which is confirmed by the statistical reports on Aversa, and lunatic asylums in this country; the age in which insanity was observed to have been most frequent was between the twentieth and fortieth year, and the ratio between male and female patients was as three to two. The latter proportion is opposed to what has been observed at the Bicêtre and Salpêtrière, where female and male lunatics had generally been admitted in the ratio of nine to five, which is, however, readily accounted for by the circumstance, that at Charenton insane military men are also admitted, which is not the case with the two other hospitals. From a comparison between the madhouses of the northern and those of the southern provinces in France, it appears that in the former the number of females, and in the latter that of male lunatics, is observed to predominate, but that, in general, the number of female to that of male lunatics, is as fourteen to eleven. Nearly the same proportion seems to exist in Spain; the madhouses of Madrid, Valencia, and Saragossa, contained by a fifth more females than males. In the Italian madhouses, on the contrary, more men are admitted than women, as particularly appears from the report on the Neapolitan hospitals, where, from 1814 to 1823, 1877 lunatics had been admitted, of whom 1323 were men, and 554 women. In the lunatic asylums of Holland the number of female is to that of male lunatics, as thirty-four to twenty-nine. In Great Britain the proportion of the two sexes is nearly equal, or thirteen males to twelve females. In the north of Europe there are, on an average, three male to two female lunatics, of which proportion, however, St. Petersburg is to be excepted, where, from 1814 to 1821, 1024 men and 433 women were admitted into the madhouses. In the United States the number of insane males predominates. All these observations combined, give the ratio of male to female lunatics as thirty-seven to thirty-eight.

In conclusion, M. Esquirol remarks that by far the greater number of lunatics at Charenton during 1826, 1827, and 1828, consisted of unmarried persons, military men, merchants, tailors, and shoemakers, and that excesses in the use of spirituous liquors and in venery, had been the most predominant causes. Of 624 lunatics, 209 were cured, 194 were discharged as incurable, and 221 died. The number of cures appears to us to be very great, but we do not recollect having ever heard of such an enormous mortality at a madhouse as that just stated, being more than a third of the whole number of patients.

## MEDICAL INSTRUCTION AT PARIS.

According to a royal ordinance, published in the *Moniteur* of the 5th of October, all vacancies at the "Faculté de Médecine" are in future to be fitted up by a "concours general," the particular mode of which is to be decided by the "Conseil d'Instruction Publique," after a report from the existing professors of the faculty. It seems, however, that the medical public at Paris has not much confidence in them, and several petitions have lately been presented to the minister of the interior by a large number of practitioners indicating what they consider to be the best mode of concours, in order to secure to the faculty such members as are most competent to fill the chairs. One of the projects mentioned in the *Lancette Françoise* strikes us as being peculiarly appropriate, and our readers will, no doubt, read the following extract with interest, though also with envy, as the wretched state of our own medical instruction leaves little hope of such a reform here, as has even already taken place in France. It is proposed that the candidate shall undergo the following trials:—

1. A strict investigation into, and discussion of, all works and papers he has published before his candidature, as well as into the "concours" he has gone through previous to the present one, the lectures he has given, &c.

2. Three extempore lectures, namely, first, a general one on the science of which he is desirous of holding the professorship; secondly, one on a particular subject relative to the same science, both after twenty-four or forty-eight hours' preparation, and a third lecture similar to the second, but after one or two hours' preparation only.

3. A thesis on a subject determined by lot; it is to be published in French, and submitted to a discussion of two hours.

4. If a clinical professorship is the object of the "concours," the candidate is, instead of the *extempore* lecture, to treat a determined number of patients at a hospital, in the presence of the jury, to take notes of these cases which appear to him worthy of commemoration; and, lastly, to give a clinical lecture on them.

## HOPITAL DE LA CHARITE.

REMOVAL OF THE THIGH ON ACCOUNT OF  
A GUN-SHOT WOUND.

*Death during the Operation.*

A SWISS officer, who had, during the three days, received a ball at the upper part of the thigh, was admitted at the hospital; the thigh-bone was found to be fractured a little

below the trochanter, and a great many pieces of bone having been extracted, a bandage was applied in order to keep the limb in extension; this was however without any effect, for the lower fragment was soon displaced, so that the limb became shortened by nearly five inches, swelled greatly, and profuse suppuration took place in spite of repeated counter-openings. The patient had unfortunately objected to the removal of the limb, which ought to have been performed as soon as possible; and it was not before hectic fever and emaciation had acceded, that he gave his consent to it. The flaps having been formed, M. Roux seemed to hesitate between amputation and exarticulation, when all at once the patient was observed to become of deadly paleness, and his mouth was spasmodically opened; the pulse was insensible, and he died in a few moments. A fatal result of the operation might almost with certainty have been anticipated from the extreme debility of the patient, but, of course, such a sudden death had not been apprehended.—*Lanc. Franç.*

## APPLICATION OF THE LIGATURE IN EPILEPSY, ATTENDED WITH AURA EPILEPTICA.

The *Decadas de Medic. y Cirurgia Pract.* contain the case of a girl about fourteen years of age, who, for nearly half a year, had been subject to monthly epileptic fits, with aura epileptica ascending from the fourth finger of the left hand, and extending up the arm to the head; the sensation of aura was always preceded by acute pain in the finger; the fits varied in violence, but always left the patient in a state of great prostration, &c. She had not yet menstruated, and as there was no other cause of the disease, the medical attendant ascribed it to the non-appearance of the menses, and treated it accordingly, advising however, at the same time, the use of the ligature above the finger, as soon as the pain was felt. In this manner the fit was always prevented, except when the ligature was not applied soon enough, or when the constriction was not of sufficient strength; the ligature was subsequently applied round the wrist, and thus never failed to act as a prophylactic up to the time when menstruation appeared, after which there was no recurrence of the fits.—*Lanc. Franç.*

MEDULLARY FUNGUS IN THE ANTERIOR  
MEDIASTINUM.

At the sitting of the Académie de Médecine on the 14th of September, M. Martin Solon communicated the following case:—A man, thirty-one years of age, and of a good constitution, had, for about two months,

been subject to pain in the præcordial region, when, on the 28th of July, he, for the first time, applied for medical advice; on percussion, which was very painful, the anterior part of the thorax presented a dull sound, and, at the same time, the "fremissement cataire," as it is called by Laennec, was distinctly perceived; respiration was perfectly audible, and the patient did not suffer from dyspnœa; after a short time, however, respiration became short, and could not be heard any more over the left side; pain in the left shoulder and difficulty of swallowing also acceded, and all these symptoms seemed to confirm the diagnosis of aneurism of the aorta, which the disease had been declared to be. At the beginning of September, when M. Solon saw the patient for the first time, the countenance was pale and œdematous; the pulse small but regular; respiration very short; the respiratory murmur audible only on the right side; the "fremissement cataire" was no longer perceived; swallowing was quite impossible, and the patient was in an extreme state of marasmus; he died on the 11th of September. On examination the anterior mediastinum was found filled by a fungous growth about three pounds in weight, eight inches in length, and about six inches in its transverse and anterior posterior diameters; it was of fatty texture, softened in a great many points, and its external portion similar to what is called medullary fungus; the left lung was forcibly compressed, and the heart pushed aside; the pericardium was of healthy structure, but closely adherent to the lateral portion of the tumour, which seemed to have originated from the fatty cellular tissue on the surface of the pericardium. The heart was one-third smaller than usual.—*Gaz. Médicale.*

#### ANEURISM OF THE ASCENDING AORTA.

By THOMAS GLASS MELHUISE, M. D.,  
M.R.C.S.

WILLIAM MURRELL, aged 42, a resident in Gibbon Street, Lambeth, whilst exerting himself in February last in favour of a candidate for the office of surgeon to the parish, was thrown from a coach, from which he experienced much uneasiness in his right shoulder and side. About three months since a small pulsating tumour made its appearance beneath the clavicle of the right side, and continued to increase, being attended with considerable dyspnœa and cough especially in the recumbent posture.

On the first of September he consulted me, when the tumour had increased to three and a half inches in its transverse, and about

the same in its perpendicular diameter, the centre being between the first and second ribs on the right side: the pulsation of the heart, compared with that of the tumour, was very trifling; his countenance was sallow, his breathing laborious, he passed restless nights; had spat phlegm streaked with venous blood; appetite good; tongue clean; bowels regular; pulse 72; he complained of his head being occasionally drawn down towards the right side, from which inconvenience he was relieved when he placed himself in the recumbent posture. I attempted to afford him relief by administering small doses of the acetate and citrate of morphia, tincture of foxglove, hydrocyanic acid, and occasional aperients; these means were beneficial for a short time, procuring for him tolerably tranquil nights, and relieving the cough and dyspnœa.

On Monday, October 11th, the tumour had assumed a purplish appearance and had increased in its perpendicular diameter to five inches, and in its transverse to seven; the face and anoles were swollen and œdematous; respiration very laborious; he was incapable of lying down, being constantly supported in a sitting posture; he complained of pricking pains in the tumour; had little rest by night or day, and had frequently spat coagula of dark-coloured blood. On Wednesday eve, the 13th inst., the tumour burst internally, when there was at the same moment heard a gurgling noise, and the poor patient immediately discharged from his mouth about a pint and a half of florid blood, and died in less than two minutes after the rupture had taken place.

#### Autopsy thirty-two hours after death.

Having made a perpendicular incision from the upper part of the sternum to the ensiform cartilage, another was made at a right angle to the first, over the centre of the tumour, extending it to the right axilla. The pectorales major and minor were quite healthy, parts of the second, third, and fourth ribs, were completely absorbed, and their extremities easily broken down with the fingers. On removing the sternum a large quantity of sero-sanguineous fluid escaped, and at least a pound of coagulated blood was found in the right pleura; the aneurismal cyst, about the size of a fetal head, was seated under the origin of the arteria innominata, and contained a large quantity of lamellated coagulum; it had burst into the inferior and posterior part of the middle lobe of the right lung, and there was a communication with the serous cavity by a rent in the pleura pulmonalis. The opening into the cyst from the ascending aorta was about the size of a halfcrown; the bronchi were

full of frothy blood. The reflected pericardium was loaded with fat externally, and contained but little fluid. The heart was of the natural size, flabby, and almost empty, the veins on its surface being distended with air. The valves of the aorta were perfectly healthy, but on the ascending and transverse portions of that vessel were discovered a few scales of ossific deposit. The stomach was distended with fecid gas, but quite healthy; the liver was of a pale colour, large, dense, and coarsely granular.

Lambeth, October 19, 1830.

DEATH OF MR. HUSKISSON—REJOINDER  
FROM DR. WEATHERILL.

To the Editor of THE LANCET.

SIR,—I am sorry the letter of surgeon Whatton, of Manchester, published in THE LANCET of last week, and purporting to be an answer to mine of the 27th ult., has disappointed me,—in one way, because it certainly fails to fulfil the writer's intentions; in another, that he should have displayed so much of teasy humour; and lastly, that he should have so far mistaken my meaning as to quote passages from my former communication merely, it would seem, to use them his own way, and contrary to what, it is quite plain, they were originally designed for.

Were I to concede to Mr. Whatton and his colleagues in this affair the full benefit of acting according to the best practice of surgery, still it must be granted the position into which his letter has thrown him, is an unfortunate one; were no other data considered, the unmanly, the repulsive temper and spirit of his language, count seriously against him; even it might be to destroy his claims to honesty in the estimation of many. That cause is weak indeed, whose vindication rests upon irrelevancy and vituperation. But with Mr. Whatton's bad philosophy and worse generalship I have less to do than with the subject on which he has exerted them.

Mr. Whatton does not believe (I can pardon his scepticism) that the consistency and professional etiquette of the faculty here, would allow them to be censorious in this case. In this, however, he is quite mistaken, and if he will not take my word for it, the testimony of others would not be difficult to obtain. The charge of imbecility, if not of ignorance, was the constant theme of conversation among the profession at the time; and, therefore, I feel justified in reiterating that portion of my former letter which speaks of the fact.

By quotation, Mr. Whatton makes me

say, "that an army or a navy surgeon might have saved the life of Mr. Huskisson." Now this was the opinion of a writer in *The North Briton*, and I caught hold of it only to expose its fallacy. My lamentation about the experience of army surgeons has however afforded a fine opportunity for Mr. Whatton (I am not offended at his dexterity nor his modesty) to say something very handsome both for himself and Mr. Ramsome.

I am now informed that a ligature was placed upon the femoral artery. When was this done? Why, several hours after the receipt of the injury, or, if you please, immediately after the medical men had made their first examination of its nature! But Mr. Whatton has not told us whether the hæmorrhage was arrested by this ligature or not; nor has he stated the time which was suffered to transpire in the consultation during and after this examination, before it was applied; he also has entirely forgotten to mention any thing concerning a reaction in the system. Mr. Huskisson was able to arrange his domestic matters, and appeared, after the first shock had passed over, composed sufficiently to converse for some time, not only rationally, but ably, with those about him. Was not this a time, I would ask, for the performance of the humane operation of Dr. Hennen? I think it was, and so do others; nor has the report of the case by Mr. Whatton, of peninsular notoriety, moved in the slightest degree the propriety of entertaining such a belief.

Most monstrous to remark, the bleeding was allowed to continue for a period of three hours or more, by "a constant draining from the veins!" This venous draining, however, was not all; there was a profuse arterial hæmorrhage, whose fury, I have good reason to believe, only abated as it overcame the strength of its victim.

It has been boldly asserted that amputation would have saved the life of Mr. Huskisson; but whether this operation would have been followed by such success or not, it was no excuse for its not being done, when this measure held out the only hope of advantage; the dread of a fatal termination should have been no intimidation; the case was of the most desperate kind, and *ad extremos morbos, extrema remedia*, is a doctrine which has been inculcated from time out of mind. "It is much better for a man to live with three limbs than to die with four."

It is always the duty of a medical man to employ every means in his power for the benefit of his patient, and Mr. Whatton will agree with me in this; if he does not, he becomes a proper object of censure. The question then to be decided is, Was every human mean employed to rescue the life of

Mr. Haskisson? I do most conscientiously, and most unequivocally, beg leave to say, there was not.

Yours obediently,  
THOMAS WEATHERILL, M.D.  
Liverpool, Oct. 26, 1830.

LETTER FROM MR. SELLS.

*To the Editor of THE LANCET.*

SIR,—Your liberal impartiality in observing the maxim of “Audi alteram partem,” assures me that you will readily insert my short notices of two passages in Mr. Morson’s defence of Mr. Bowen.

To that of “Mr. Bowen and myself having met each other frequently,”—I have to deny it entirely, having never even seen him from the period of Mrs. Clarke’s death, until after Sir A. Halliday stopped me in the street at Hampton, and said to me, “I’ve seen Bowen, it’s all lies; he opened the head, and delivered the woman.”

To the equivocal passage of his believing something, and about my not coming forward at the meeting or council held at Mr. Jackson’s on Aug. 26th, I have to express my opinion that it never was intended I should be present, as I had no information, direct or indirect, of when it was to take place, and knew not of such meeting having occurred until two days afterwards.

I remain, Sir,  
Your most obedient servant,  
WILLIAM SELLS.

Kington, Nov. 2d, 1830.

SUMMER LECTURES ON SURGERY.

*To the Editor of THE LANCET.*

SIR,—In your last Number of THE LANCET, in answer to your correspondent, “A Medical Student,” I perceive that you are not aware that the Court of Examiners of the Royal College of Surgeons will receive a certificate of a summer course of lectures on surgery, duly delivered between the months of May and October, and including, like the winter course, not less than sixty lectures, which I am now delivering, and shall recommence on the 1st of June, 1831. I have by me a letter from the secretary of the College, in answer to one from me, dated 1st of October, stating that my summer course will be received.

I am, Sir, yours obediently,  
J. EVANS RIADORE.  
17, Tavistock Square, Nov. 1st, 1830.

MOTIONS OF THE HEART.

*To the Editor of THE LANCET.*

SIR,—In reading yesterday, in THE LANCET, your very excellent and candid review of Dr. Corrigan’s opinions on the motions of the heart, and the cause of the impulse of the heart on the chest, I was struck by the fact, that both Dr. Hope and Dr. Corrigan, as well as the reviewer, in speaking of the tendency which a flexible tube has either to become straightened or still more bent upon the injection of a fluid, omitted to consider the influence of the form of the tube—I mean the shape of its cavity—or, to speak in a different manner, that they overlooked this, viz. that the injection of a fluid into a tube of flexible materials would (particularly if its passage through were in some measure resisted) cause the sides of the tube to assume that position in which the cavity of the tube became the greatest.

Therefore, upon the injection of a fluid into a tube of flexible materials (like the aorta), with some degree of resistance to its passage off at the other end, the tube would become either more straightened or bent than it was before the injection, according to the position of the tube when partially empty or flaccid, in relation to its position when distended to the utmost.

If you think these observations worth insertion, will you favour me by giving them a place in your Journal.

I remain yours,  
H. P. L. DREW.  
Thursday, October 7, 1830.  
79, Gower Street.

TO CORRESPONDENTS.

The whole of the letters requiring answers will be noticed in our next. The Index to the last volume will also be published with our succeeding Number.

*A Married Medical Assistant.* He cannot dispense his own medicines without being liable to the penalties in question, although he may not style himself “Apothecary.” Neither will a court of law assist him to recover debts for medicines and attendance.

The letter of *Hiatus* must be authenticated.

The letter of *H. F.*, Bristol, was mislaid, and we presume that an answer to it would not now be desired.

We have not addressed a letter to our correspondent *H. R.*, of Leominster, because we cannot yet give him all the information he desires; but whenever the arrangements are complete, ample opportunities of becoming acquainted with them will be afforded in this Journal.

# THE LANCET.

Vol. I.]

LONDON, SATURDAY, NOVEMBER 13.

[1830-31.]

*Dublin Hospital Reports, and Communications in Medicine and Surgery.* Vol. V.  
Dublin: Hodges and Smith. 1830. 8vo.  
pp. 631.

Of this excellent volume we should speak in lengthened terms of approbation, but the abstract we propose to make of its most prominent papers, will entirely supersede the necessity of our eulogium. The subsequent "sample" will enable our readers to estimate the value of the entire volume.

A joint report from Dr. Graves and Dr. Stokes, the physicians to the Meath Hospital, occupies a hundred and twenty-eight pages of the volume. It is subdivided into different sections on diseases of the arterial system, painful swellings of the extremities, disease of the lymphatics, diseases of the respiratory organs, and of the abdominal viscera. Of each of these topics they have given able and well-illustrated notices. The first section includes a most remarkable case of arteritis, to the abstract of which we would call the most serious attention. On the 7th of February, 1829, Patrick McGrath, ætat. 44, of strong habit, was admitted, labouring under loss of power of the right lower extremity. He had been exposed to considerable hardships for six months, and in the beginning of the previous December, was first affected with alternating sensations of cold and heat in the toes of the right foot. Soon after the same sensations were experienced in the leg, with fornications and partial loss of power. Pains of the foot next supervened, in a month the part became cold and deprived of sensation.

On admission, the temperature of the body was natural, except in the affected limb, which was as low as 58° Fahrenheit; the pulse 96, small, and soft. There was complete loss of sensation from the middle

of the thigh to the toes. The femoral artery was hard and painful, and in it no pulsation could be felt; the stethoscope further indicated absence of pulsation in the external and common iliac arteries of the affected side. The authors hence concluded, that the right common external iliac and femoral arteries, were in a state of permanent obstruction. Warmth was applied to the limb, and opiates exhibited. In the night the temperature of the parts rose to the natural standard, and the thigh became generally painful on pressure. Leeches were applied, and opium freely given; the next day the thigh was more swollen, vesications appeared, and he died on the subsequent morning.

We omit the notice of the dissection of the general cavities, and proceed to that of the arterial system: the descending aorta was healthy to within six inches of the bifurcation; here a slender red fibrinous clot was found stretching nearly to the bifurcation, beneath this clot the lining membrane was of a deep-red colour, thickened, and soft. On slitting down to the bifurcation, the right common iliac was found completely plugged up from its origin by a dark clot, which extended to the external and internal iliacs, and also engaged the gluteal and obturator arteries; the same disease was found in the femoral and profunda, and extended to the origin of the anterior and posterior tibial arteries, which vessels, including the peroneal, presented a similar appearance as far as they could be traced. Along the course of the diseased vessels, the lining membrane was found soft and thickened. It had somewhat a villous appearance, and greatly resembled an inflamed mucous membrane. No disease whatever could be detected in the veins of the affected limb.

On these symptoms and pathological appearances, the authors comment with great ability. They notice, in the first place, the commencement of the disease in the extreme arteries of the foot, and its gradual extent upwards, as proved by the consecutive progression of the coldness and pain in that direction. They observe that the coldness of the foot, while the thigh generally retained its standard warmth, indicated the affection of the ultimate branches, while the larger were yet disengaged, and that the dissection still more forcibly corroborated this opinion, by exhibiting the clot increasing in consistence from above downwards. They consider that, in this case, the clot differed in its origin and nature from that which constitutes aneurismal coagula, and which proceeds from the coagulation of blood arrested in its course. Here they think it probable that the obstruction originated from the effusion of lymph poured out from the inflamed lining membrane of the arteries, augmented perhaps by the subsequent coagulation of impeded blood.

Further, they apply with much ingenuity the detail of the symptoms to the corresponding evidence which the dissection produced. "In this case," they observe, "the extreme coldness of the limb pointed out, in the first instance, that the circulation was obstructed. Coldness occurs in some cases of paralysis from disease of the nervous system, but it is slight; here the temperature of the affected limb was  $30^{\circ}$  below the natural standard. This great coldness, and the slight and but little extended oedema observable on the admission of the patient, showed that the obstruction existed in the arterial rather than the venous system, and this was borne out by the absence of pulsation in the femoral artery, as observed by the touch, and in the iliacs by auscultation.

One of the most interesting circumstances in the case they consider to be, the occurrence of inflammatory action in the cellular tissue and skin of the affected limb towards the close of the disease; this they believe to have proceeded from a natural effort towards the restoration of the circulation, by means of anastomosing branches from the healthy arteries of the opposite side. From over-action thus induced, they believe the external inflammation to have arisen; and

they argue, that if their views be correct, the application of warmth must be injudicious, after the collateral circulation has commenced; on the same principle that warm applications are improper, or even dangerous, in the case of frost-bitten parts.

As to the diagnosis of this disease, they do not consider it to be difficult, in the advanced stages; "there is paralysis, but this has not been preceded by symptoms of cerebral or spinal disease, and the intellects remain undisturbed. To this the feeble pulsation, or its complete absence, in the arteries of the limb, are to be added, and no difficulty will be experienced in detecting the disease."

We question much how far the intellectual condition can be admitted as an item in this diagnostic evidence. Paralysis of one of the lower extremities by itself, but rarely, if ever, arises from cerebral disturbance alone, and we have seen almost innumerable examples of spinal disease, in which the intellects continued totally unclouded to the last moment. But to resume the author's observations:—

"In its early stages," they continue, "the diagnosis is more difficult. Here, however, an accurate comparison of the temperature of both limbs, and the force of the arterial pulsations, may, perhaps, lead to a discovery of the disease soon after its commencement, and thus enable us to arrest the progress of the inflammation. At all events the disease might be checked, if not cured, so as to allow the anastomosing vessels time to take on the supplementary action."

We pass by the other arterial cases which the authors describe, but which are possessed of deep interest, and we proceed to the section which relates to painful swellings of the extremities, and which contains an abundance of the most important practical information. It is moreover distinguished by the creditable candour in which they contrast their own views with the opinions of others, and draw from their practice cases to a certain extent contradictory to the opinions they had previously expressed. Of painful swellings of the extremities, they describe three cases:—The first occurred in a man named Andrews, who was admitted for apparent tertian ague, at the same time labouring under swelling of the left leg and thigh, but which affection he concealed. As several other cases of ague were in the

house at the same time, the ordinary treatment by the sulphate of quinine was adopted, which, to the surprise of the medical attendants, seemed to exert but little influence on the disease. The true nature of his illness was then discovered. The left leg and thigh were extremely painful and swollen; the limb was very tender on pressure, *particularly along the course of the saphena vein*, which, in its whole extent, felt like a hard chord. The temperature of the parts was not increased. The quinine was now omitted, leeches were applied, and calomel and opium exhibited. This treatment proved successful, and in three weeks he was discharged well.

The second case was one of more serious character:—The patient, Eliza O'Donnel, *ætat.* 21, was admitted on the 3d of June, 1839, with symptoms of gastric fever and pain in the right side; thirty leeches were applied, and aperient medicines given. Convalescence appeared to commence on the 6th; but on the 7th, without any obvious cause, it was found that a violent pain had occurred during the night in the calf of the left leg, which was extremely tender, hot, and tense, but free from redness, and did not pit upon pressure; *the tenderness was especially great along the course of the saphena vein*, which felt chordy in its whole extent. The pulse was 108, hard.

Leeches were applied along the vein, calomel and opium, and the hip-bath employed, and in a few days her symptoms were relieved; but a decided tendency to a recurrence of the disease manifested itself on several occasions, proving exceedingly distressing, but eventually yielding to leeches and stupes, so that she had nearly recovered by the middle of July.

With reference to the case of Andrews, the authors, in the first place, remark on the striking example it furnishes of the danger that may arise from neglect of accurate examination in any case, however simple in appearance, and in further illustration of this circumstance, they adduce another example of the same disease:—

"In a female patient, much debilitated by fever, convalescence had but commenced, when she complained of want of sleep from severe pain in the calf of the right leg. At this time we were not familiar with the disease. On examination of the limb, the skin was of the natural colour, and it did not ap-

pear increased in size, or swollen in the least. Narcotics were exhibited, but without benefit, and on the following day, the pain being very severe, and occupying a small spot on the leg, a moxa was applied. Next day, on taking down the bed-clothes, the left leg was accidentally uncovered, when we were at once struck with the great difference of size of the two extremities. The right, which we had supposed of natural size, was nearly twice as large as the left, which was emaciated from the long continuance of the fever."

The apparent intermittent fever in Andrews, they compare to that produced by urinary irritation, and they offer some very judicious remarks on the exasperation of these cases by the use of the sulphate of quinine. In one case of another description, they even noticed well-marked tertian ague to supervene *during the administration of large doses of this medicine.*

The disputed pathology of these swellings next engages their attention; "An accurate observation," they state, "of numerous cases both of phlegmasia dolens occurring after delivery, and of painful swellings of the extremities appearing during or after fever, has satisfied us of the pathological identity of the two diseases." This conviction they found on the similarity, if not identity of symptoms, their occupying at one time the entire limb, at another only parts of it, and changing from site to site in an erratic form.

"In some cases," they continue, "we have observed this affection to be attended by a cordy and painful state of the saphena vein, proving that it participated in the disease; but as this state of the vein, when it did occur, was in some cases subsequent to the disease in other parts of the limb; and as in the majority of cases of phlegmasia dolens, and in the painful swelling of the extremities after fever in the male and female subject, no such affection of the saphena occurred, we think that the latter cannot in justice be considered as the cause of the disease. The occasional occurrence of the swelling in the inferior portion of the limb, in the first instance, and its erratic nature, militate against the idea that the disease proceeds from an affection of the large venous trunks."

Several circumstances, which we need not mention in detail, induce Dr. Graves and Dr. Stokes to refer the primary seat of the disease to the subcutaneous cellular tissue; the external and vascular layer of the corium

remaining uninfamed will account, they believe, for the absence of redness in such cases. When leeches were applied, they observed a quantity of serous fluid to flow from the bites before blood appeared, and this fact they apply to the confirmation of their opinion on the grounds that "the cellular tissue seems to follow the same law as serous membranes; moderately inflamed it effuses an unusual quantity of its natural secretion, serum; when the irritation is more intense, the effusion is also altered, it contains more animal matter, approaching in its qualities to coagulable lymph, and sometimes it is of a puriform nature; in this latter form it is occasionally noticed in intense cases of the true phlegmasia dolens, but usually the secretion is intermediate between the serous and puriform nature."

All these arguments, it will be observed, tend to contradict the recently prevailing opinion that phlegmasia dolens is produced by phlebitis of the veins of the limb. It is worthy of notice, however, that the saphena vein was, in point of fact, inflamed in all these cases, and certainly we do not attach the same importance as the authors, to its apparently supervening after the swelling and not preceding it, as the cause should its effect. For, it is plain that the internal or deep-seated veins may be inflamed beyond the reach of our examination; that a tendency to this state may exist in the external veins, and thus that both may induce the peculiar swelling of the limb, before the progress of the phlebitis renders itself manifest in the condition of the saphena veins. In these remarks we are borne out by a case which occurred, subsequently to the writing of the authors' conjoint statement, and which they with the utmost candour describe. A young man was admitted labouring under typhoid fever, but chiefly complaining of severe pain in the upper and anterior portion of the right thigh. The limb became swollen, and four days after admission he died. On dissection, besides the evidences of pleuropneumony, pericarditis, and splenitis, the following appearances were observed in the venous system of the affected limb.

"In the external iliac vein, we found just above Poupart's ligament, a large concretion of a granular appearance, friable, and of a yellowish colour, nearly plugging up the vessel, and extending into some of the

minute collateral branches; the lining membrane was red, and in one point adhered to the coagulum; no puriform matter could be detected; the femoral and popliteal veins were healthy, as also the arteries; the cellular tissue of the limb was pale and cedematous." It cannot be denied, they add, "that this case is strongly corroborative of the opinion before entertained, and lately insisted on by Tommasini, that the phlegmasia alba dolens is in reality owing to phlebitis. It would, however, be unphilosophical to form certain conclusions as to the disease in question from a single case. We have put our experience of the disease now on record, and leave to our readers to form their own opinion."

There next follows an instructive case of psoas abscess which terminated suddenly, and in which, on dissection, a singular lymphatic affection was discovered. The internal surface of the abscess was quite smooth, as if it had been lined with serous membrane, and towards its infero-posterior portion there existed five or six orifices of the diameter of peas, with surfaces perfectly continuous with that of the sac. They terminated in organised tubes, which appeared to be lymphatics, for they led to a mass of diseased glands which lay on the brim of the pelvis. The vessels between the lymphatic glands and the abscess were filled with pus precisely similar to that in the abscess, while the glands were distended with matter evidently of similar origin, but changed in its physical properties. In some it was still fluid, but much thicker than in the abscess; in most it was converted into a soft cheesy mass. From these glands ascended a chain of lymphatics communicating with the thoracic duct, and containing solid matter resembling that of tubercles. The thoracic duct was distended to the size of the middle-finger, and felt hard and nodulated. It was found to contain a similar matter, but much harder in consistence, and mixed with a large proportion of a calcareous substance, such as occurs in diseased bronchial glands. The uterus was filled with a mass of the caseous matter.

The authors consider this case of much pathological importance, with reference to the changes observed in pulmonary tubercles. Still they build no theory on the foundation it affords; neither do they, by its assistance, endeavour to prop up any hypothesis already advanced; they judiciously content them-

selves by merely observing the fact of pus having in this instance been converted into matter of a caseous consistence, of the absorption of its fluid particles, the new arrangement of its solid particles, its assuming all the physical characters of solid tubercular matter, and like this finally passing into a state in which its calcareous matters predominate over the other ingredients.

The ensuing forty pages are occupied by extremely interesting cases with remarks on the diseases of the respiratory organs. Of these our notice must be very short. By a summary of the cases it appears that acute inflammation of the pulmonary tissue and of the bronchial mucous membrane, are the prevalent inflammatory diseases of the respiratory organs, and that simple pleuritis is in Dublin a very rare disease. Simple pneumonia, they found, was most advantageously treated by venesection and tartar emetic, and of the mode of exhibiting the latter they afford much novel and highly valuable information; they find that its use is most suitable in the *early* stages of the disease, in strong constitutions, and during the absence of gastric symptoms. The cases which resisted the use of the remedy were entirely such as combined gastro-enteritis with the pneumonic inflammation, and they have found that after leeching the abdomen and thus removing the gastro-enteritis, that then the tartar emetic operated with its accustomed efficacy. Six grains are generally administered the first day, and the dose is increased by two or three grains daily, until fifteen grains are exhibited in the twenty-four hours. At this rate they have been able to administer it for several days, always with the best effects, and seldom or never inducing the slightest abdominal irritation, further than occasional colicky pains which yielded to mild laxatives, stuping, and opiates.

In cases where a complication with abdominal disease decidedly exists, where the fever is low, and the powers of life greatly sunk, they have found the active administration of calomel and opium, followed up by the decoction of polygala, and other stimulants, to have succeeded in the most remarkable manner.

We cannot omit to notice some facts connected with the use of the stethoscope, which are of the utmost practical importance,

and which the authors explain in a masterly manner. The first is, the occasional disappearance of hepatization without the occurrence of the "crepitus" of resolution. The second respects the sonorous rale, and is of the deepest practical importance. In several cases of the worst catarrhal fever, while the patient was in a semi-comatose condition, nothing is often observable by the stethoscope during ordinary respiration, though a loud sonorous sound is heard upon a deep respiration. Where the fever, however, is on the wane, when convalescence is setting in, and the patient in every respect improved, then a loud sonorous rale is heard even in ordinary respiration, owing to a diminution of inflammatory action, and not to its increase, as an inexperienced stethoscopist might readily imagine.

The great modifications which laryngeal affections create in the stethoscopic evidence of pulmonary disease, is made the subject of lengthened observations. A singular phenomenon is also noticed of the formation of temporary tumours on the percussed parts of the chest in tubercular phthisis. Some cases of phthisis are alluded to, in which the pulse was full and slow, contrary to that state of quickness which, by many authorities, is even considered as diagnostic of the disease. A case is also cited, in which, notwithstanding the destruction of the greater part of the lungs, the calorific functions were increased in activity. Finally, a most extraordinary instance of malformation is described, in which the stomach lay within the thorax, above the diaphragm, and completely beyond the reach of its contractions. Vomiting occurred continually during the patient's illness, "a fact," as they observe, "worth a thousand experiments, and which completely decides the question that vomiting may be produced by the action of the stomach itself, unassisted by any external compressing force, notwithstanding what Le Gallois and late physiologists have said to the contrary."

Our limits will hardly permit us to give a detailed notice of the concluding portion of this paper; where it relates to the diseases of the abdominal viscera, two points of great importance are therein minutely examined and illustrated; namely, the operation of opening hepatic abscesses, and peritonitis consecutive on perforation of the intestines,

a disorder which has of late been almost epidemic in some of the Dublin hospitals, and requires very peculiar treatment, of which we can say no more than that venesection appears to be hurtful, and opium in large doses of the most unequivocal advantage.

We shall return to this volume again at an early occasion, having in the mean time given, we believe, sufficient proof of its worth, to justify the opinion we expressed at the commencement of our abstract.

*Medico-Chirurgical Transactions.*  
Vol. XVI. Part I.

(Continued from page 218.)

The first part of the 9th paper, by Mr. A. C. Hutchison, on the infrequency of calculous diseases in seafaring persons, merely confirms the statements made by him in his former essay on the same subject, and requires, therefore, no particular notice here. The second part "on the frequency of calculous diseases in Scotland," shows, that contrary to the general opinion, these diseases are, on the whole, more prevalent there than in England, the proportion being one in 83,000, though only cases observed in the principal towns are included in the calculation; while in England, according to Dr. Yelloly's statement, it is only one in 108,000. The cause of this frequency, Mr. Hutchison does not attempt to explain, otherwise than by observing, that "it may possibly be owing to the more sedentary occupations of the Scottish people." He seems, indeed, to think, that it may also be in some measure owing to the nature of the food in general use among the lower orders, but does not in any way point out how this could have such an effect.

Of the 10th paper, by Mr. Langstaff, and entitled "practical observations on the healthy and morbid conditions of stumps," it is difficult to give any thing like an analysis; it consists chiefly of descriptions of a number of preparations in his museum, which, apart from the preparations themselves, can of course have but little value. They are, indeed, preceded by a very accurate account of the healthy actions which usually take place in stumps after amputation; but of the causes of the morbid changes, especially the enlargement of the extremities of the divided

nerves, which form the particular subject of the paper, and which the preparations described are intended to illustrate, Mr. Langstaff does not attempt the least explanation; and though he promises at the beginning of the paper to describe the method he has adopted most successfully in making a good stump, and rendering the parts capable of receiving any mechanical assistance, yet all that he subsequently states on this point is, that the flap operation is preferable to the circular, and that too much muscle ought not to be left, as it is injurious, by impeding the adhesive process, the absorbents having to remove the unnecessary parts of the muscles before this process can be established. We confess, therefore, that these "practical observations" have disappointed us, and that they are not altogether such as might have been expected from so accurate an observer, and so intelligent and experienced a pathologist.

No. 11, is an account of a case of aneurisms of the external iliac and popliteal arteries, in which the common iliac was tied by Dr. Crampton, of Dublin. The operation was performed in the same manner as that in which Dr. Stevens first tied the internal iliac, the incision being made downwards from the last rib along the crista ilii, and the peritoneum being separated from the fascia iliaca without division. The vessel was thus completely exposed to view, and a ligature passed round it without the least difficulty. The patient appeared to be going on well, except that some degree of pulsation returned in the iliac tumour on the second day after the operation, and the ligature, which was of catgut, came away on the 8th; but on the 10th day violent hæmorrhage suddenly occurred from the wound, which was nearly healed, and proved almost instantaneously fatal. On dissection the artery was found to be still pervious, though the internal and middle coats were completely divided in its whole circumference and small portions of lymph adhered to its external surface. The state of the contents of the iliac aneurism is not mentioned, nor whence the fatal hæmorrhage proceeded; we suppose, however, that it was from an ulcerated aperture at the point where the ligature had been applied, as it is stated that a small abscess had formed there. The return of the pulsation, and the unfortunate

event in this case, seem evidently to have been owing to the softening of the ligature, "by which it was thrown off before the obstruction of the artery, or the coagulation of the blood in the aneurismal sac, had been completed." No reason is given why a catgut ligature was used in preference to a silken one, the employment of which would probably have ensured success to an operation undertaken under favourable circumstances, and in other respects admirably executed. It is somewhat remarkable, that at the end of this paper Dr. Crampton speaks of the operation of tying the aorta as though it had never yet been performed.

The 12th paper, the longest, and perhaps the most interesting of all, is by Dr. Elliotson, on glanders in the human subject. Two patients labouring under this terrible disease were admitted into St. Thomas' Hospital in the course of last year, and the case of the first, who was under Dr. Roots, is described in our 291st Number, under the title of "gangrene of the nose." In that of the second, who was under Dr. Elliotson, the progress of the disease was more rapid, and the symptoms were more strongly marked, but in both cases they were essentially the same: typhoid fever, with great prostration of strength; abscesses in different parts of the extremities; pustules on the face, especially on and around the *alæ nasi*; gangrene of the extremity of the nose, and a profuse discharge of fetid pus from the nostrils. Although both these cases were seen by most of the medical officers of the hospital, as well as by several other practitioners and a great number of students, no one appears to have been at all aware of their real nature. Even Dr. Elliotson, who was satisfied that the disease depended on some morbid poison, was quite unable to indicate its source, especially as the friends of both the patients, who were particularly questioned on the subject, positively denied that they had ever been exposed to any kind of contagion which could be supposed capable of producing such effects. It was, therefore, some days after the death of the second patient, and on seeing "fatal case of acute glanders" on the cover of a contemporary journal, that "the truth instantly flashed upon his mind." On reading the history of this case, which occurred in a cavalry soldier in Ireland, and under circumstances which placed the source

of the contagion beyond all doubt, Dr. Elliotson was fully satisfied of its identity with the two which he had lately observed. With this clue he recommenced his inquiry, and after much difficulty and delay succeeded in ascertaining, that in both instances the patient had been in frequent contact with a glandered horse, in the advanced stage of the disease, a short time before the commencement of the fatal affection, and under circumstances which clearly showed how it had originated. To the account of the two cases above-mentioned, and of the circumstances connected with them, Dr. Elliotson has added that of a third, which occurred not long afterwards to Mr. Parrott of Clapham, two from Mr. Travers' work on irritation, and several others from German medical journals, one of which was written so long ago as 1821, so that the disease must be pretty well known in that country. All these cases agree in every essential point; and it is not a little remarkable, that although in one of Mr. Travers' cases true glanders was actually produced in an ass by inoculation with the matter of the patient's sores, he, with a singular degree of blindness, or prejudice, regarded them as cases of mere irritation, and not of a specific disease; and did not appear, when he saw the two patients in St. Thomas's Hospital, to have the least idea that they were labouring under a similar affection.

Considering the great number of glandered and farced horses, there can be little doubt that the disease in question, though not hitherto understood in this country, is not of very unfrequent occurrence, and great merit is due to Dr. Elliotson for having clearly established the fact, that the infection of glanders is communicable to the human subject, a fact which cannot be too generally known and acted upon, and the knowledge of which may save many individuals from a dreadful and destructive disease, against which, like hydrophobia, medical science is of but little avail.

The 13th and last paper, contains an account of the dissection of the pelvis of the patient on whom the operation of tying the internal iliac artery was first performed, in 1812, by Dr. Stevens, of Santa Cruz, for aneurism of the ischiatic artery, and who died ten years afterwards of some thoracic affection. The preparation having been

lately brought to England by Dr. Stevens, was deposited by him in the museum of the College of Surgeons, and there examined by Mr. Owen. The artery was found to be entirely obliterated for the space of an inch where the ligature had been applied, but to retain its natural diameter for half an inch above its division. The obturator artery, which arose from the upper part of this pervious portion, was, as well as the ischiatic, entirely obliterated; but—

“The sacro-lateral artery was pervious, of the size of a crow-quill, and passed inwards to the second sacral foramen, whilst the gluteal artery of its natural size, received close to its origin, two vessels as large as the preceding, given off from the sacro-lateral artery near the third and fourth sacral foramina of the left side; the anastomoses of the sacro-lateral arteries with each other, and the sacra-media, were large and tortuous.”

The remains of the aneurismal tumour, about three inches and a half in length and two and a third in breadth,—

“Consisted of layers of condensed cellular membrane, and the peculiar fibrous arterial coat; it contained a quantity of dark-coloured granular, not lamellated coagulum, which, when removed, showed the internal surface of the sac to be somewhat irregular and raised in small patches by the deposition of soft matter,” &c.

To this statement Mr. Owen has added some account of two of the other four cases in which the internal iliac has been tied, but as these have been already published we need not notice them here.

#### ON THE USE OF THE STETHOSCOPE

FOR THE DETECTION OF  
TWINS IN UTERO, THE PRESEN-  
TATION, &c. &c.,

By DAVID C. NAGLE, A.M.M.B., *Trinity  
College, Dublin.*

*Est quodam prodire tenus, si non datur ultra.*

THE perfection to which the stethoscope, so invaluable in the hands of the observant and discriminating physician, as a means of discovering the diseases of the chest, may be brought in the practice of midwifery also, will, I trust, be conceded with less reluctance than heretofore, after a perusal of the two following cases.

That auscultation has been used with decided advantage for the discovery of pregnancy, when all other means were found insufficient, is a fact that will not be denied, except by those who, from the imperfect nature of their education, or from physical impediments, have felt it an absolute impossibility to use it with even the slightest beneficial result. The following case will prove, that by it we are supplied with the most satisfactory means of discovering the existence even of twins; that we can, in most cases, determine the progress of the labour, and even the kind of presentation, without having recourse so often to the disagreeable, and frequently objectionable, mode of examination per vaginam.

On the 15th instant, a female, aged about 30, and in her first pregnancy, was admitted into the Lying-in Hospital, Dublin. The abdomen was, in this case, so enlarged as to lead to the suspicion of twins; and on the next morning my attention was directed to the patient by one of the nurses. Having applied the stethoscope, with a sheet interposed between its sternal extremity and the abdomen, I found a fetal heart to pulsate strongly, rapidly, and rather irregularly, midway between the umbilicus and the superior anterior spinous process of the left ilium. By a minute examination I satisfied myself that the cylinder was applied immediately over the fetal heart, with the rhythm of which I took particular care to make myself familiar. I next directed my attention to the other parts of the abdomen, still hearing the pulsations of a fetal heart, until I came on a point where they were most distinctly audible. This greater distinctness of resonance I found to be nearly under the linea semilunaris, between the umbilicus and the anterior inferior spinous process of the right ilium. The pulsations here I immediately recognised to be weaker, less rapid, and less regular in rhythm, varying from 125 to 133 in a minute, whilst those on the left side varied from 160 to 170. The patient, labouring under a smart bronchitis, was occasionally attacked with a severe fit of coughing, during which, the abdomen receiving a strong concussion, the pulsations of the fetal heart, on the right side, were remarkably accelerated, whilst those on the left were scarcely at all affected.

In order to draw a diagnosis, I compared, with as much accuracy as I was capable, the pulsations on both sides with each other, and then each separately with the impulse at the chest, and the pulsations at the wrist, of the mother. The diagnosis was, that there were twins; and I may add, that auscultation induced me to predict, that the head of the second child would present.

The announcement of this discovery was

received with considerable interest by some whom I took to examine the case; and Dr. Collins, the highly respectable master of the Hospital, was so satisfied of the accuracy of the diagnosis, that he declared "he could no longer repose confidence in the stethoscope in the practice of midwifery if the case did not prove to be twins." The patient, owing to a want of action in the uterus, continued to suffer a tedious, and at times a distressing, labour, until the night of the 20th, when, after the use of 45 grains of the ergot of rye, in divided doses, which at first quickened, then lowered the pulse, and evidently soon produced some slight action in the uterus, she was delivered of twins, the heads of both presenting, the delivery of the second being assisted with the forceps. From the nature and length of the woman's labour both children were dead; the second exhibiting the appearance of having been alive a short time previous to birth. The placenta in this case was single, and had to be removed by art.

Whether the following case will be considered interesting or not by the readers of THE LANCET, I will not venture an opinion, but I am induced to give it from a feeling, which I trust will ever direct me in my professional career, that by communicating to the profession whatever I find unusual, or likely to tend towards the advancement of science, I shall, *pro virili*, be discharging a duty which I think the members of a liberal profession owe to each other.

I was accidentally informed, on the 20th inst., that there was in the Lying-in Hospital, since the 16th, a patient who was not then delivered. Anxious to make some observations on the "placental murmur," as it is usually designated, I called to see the woman. She had then some smart labour pains; was 27 years old; married for three years, but had borne no child previous to her present pregnancy. Whilst preparing for the examination I proposed, I was informed by the patient, that "she was certain her child was dead, as she did not for some time feel it to stir." On the first application of the cylinder, I was enabled to assure her that her child was still alive. The phenomena first observed excited my curiosity, and pursuing my examination, I collected the following groups of symptoms, which, before delivery, I carefully committed to my note-book. Size and form of the abdomen not remarkable, as in the former case; stethoscopic symptoms peculiar and rather obscure; near the left hypochondrium a foetal heart pulsates strongly, very irregularly, but very distinctly, is occasionally exceedingly intermittent, not easily distinguishable from the pulsations at the mother's wrist, which are very quick, but dis-

tinguished with facility on comparison with the rhythm of the parent's heart. I found it to become, on a sudden, remarkably slow for a short time, much more so, indeed, than the ordinary action of an adult's heart, but soon to recover, quite unexpectedly, its natural rapidity. Immediately above the anterior inferior spinous process of the right ilium, the foetal heart is found to pulsate with rather more clearness than over any other part of the abdomen, except for a few inches in the region between the umbilicus and left hypochondrium. The rhythm in both places very nearly corresponded, except when the heart on the left side assumed that singularly slow action. The heart's action in the right ileum was a little weaker and often more rapid, more regular than that on the left side, and assuming no intermission of any consequence.

So much was I enabled to ascertain on my first examination at four o'clock. I had to leave the Hospital, requesting one of the midwives "to watch the case for me, as I was interested in the result for reasons I should afterwards explain."

Examination was resumed at half-past seven o'clock on the same day. Heart's action heard at the same relative distance, but not exactly in the same parts as at four o'clock, that on the right side having approached nearer to the pubes; that on the left nearer to the umbilicus. The heart on the left side not now irregular, nor in the slightest degree intermittent—stronger, but a little slower than that in the right ileum, where it is rapid, a little irregular in its rhythm, lower in the pelvis, and rather weaker than when last examined. Diagnosis:—"I have not the slightest doubt that it is a *twin case*, and, from the phenomena obtained by auscultation, I would be strongly inclined to think that the feet or breech of the second child will present." Previously to any examination per vaginam, auscultation enabled me to conclude, that the head of the first child was in the pelvis. Delivery of twins at eleven o'clock that night; the first dead, but with the appearance of having been recently alive; *breech and feet* of the second presenting; this a healthy-looking child, and much larger than the other two placentas in this case; a smart hæmorrhage.

Circumstances which occurred after the discovery in the first case prevented me, until the patient should be free from danger, from making known what I had ascertained in this, but I recommended some of the pupils to wait for the result of the case; and immediately on the expulsion of the first child, I read for them my notes and the diagnosis I drew.

In order to arrive at the conclusions I came to, I paid particular attention to the

points and the relative distances at which the fetal hearts were, in each case, most distinctly audible; and whenever I detected the slightest variation in the pulsations at one point, I instantly removed the cylinder to the other, in order to ascertain if the same change was observable there also. This must be done with the least possible loss of time, and with great accuracy of auscultation. When there is only a single fœtus, the auscultator must have observed that, whilst counting the pulsations of the fetal heart, he is frequently obliged to desist, in consequence of the fœtus suddenly changing its position in the uterus, except when the head has descended into the pelvis. This change of position I have not observed to take place in case of twins; hence the utility of observing the relative distances. The fetal circulation, in cases where there is but one fœtus, is not, I find, so liable to alteration in rapidity as when there are twins; and to the physiologist it may appear a curious fact, that when the pulsations of one fœtus in the latter of the two cases I have given were accelerated, those of the other would appear to have lost something of their wonted rapidity.

October 23, 1830.

#### ON THE "PYRAMID," AND "PÈRE LA CHAISE."

By THOMAS WILLSON, Esq., *Architect*.

THE General Cemetery question having now permanently engaged the public attention, it is desirable to consider it deliberately, and without prejudice; it is therefore requisite to trace its origin, and minutely examine the merits of the plans.

One of them is the design of an architect, the other is a proposition originating with a gentleman at the bar. The first of these plans was submitted to government in the year 1827, and was duly laid before the late King as well as his present Majesty. The novelty of a Mausoleum, upon a scale that contemplated interment of the millions, at once attracted the attention of the public journals, and as is usual with first impressions, met with sarcasm and wit, rather than examination. The notice of the press obtained for it the attention of men of science, and it was pronounced "one of the noblest conceptions of the age." The encouragement given to it by this class induced the architect to examine his project more attentively, and with a view to its practicability, to consider how far it could be simplified, and reduced, without prejudicing its grand feature, to a principle of economy; so that in every point of view it might be desirable for the adoption of the

public. The result of these inquiries, from the minutest calculations, exhibits upon the whole an extraordinary saving, in the course of one century, of several millions sterling! Hence the busy speculators of the day were induced to make inquiry for the Star of the West, which was to direct them to reap a rich harvest of interest upon invested capital. Under this influence, the barrister alluded to made his first visit at the Pyramid Office in May, 1829; his proffered friendship and alliance to the project were received with the utmost cordiality, and the most perfect union of interests was entered into, cemented by professions of honour and implied mutuality of good faith, inasmuch that reciprocity of interests, as well as the assurance of devotedness, opened the heart to the most perfect friendship and unreserved communication. Profiting by this, the learned gentleman, glowing in the ardour of unbounded ambition, and having recourse to the portfolio of his friend, possessed himself of the Pyramid, in detail, and liked it so well, that he borrowed the original before it was signed, and without permission, or further ado, took the said plans home with him, and exhibited them to his personal acquaintance as "a project of his own invention;" kept these plans for several months in spite of all remonstrance and expostulation, notwithstanding he had pledged his word to return them the following day; and finally, to crown all, this most honourable gentleman endeavoured to concoct the celebrated Pyramid Society at Paris, the plagiarism of which the real projector was under the necessity of exposing in the English newspapers; he, however, could form no conception that this bold and foul attempt was the work of his confidential friend; and still confiding in the worthy gentleman's integrity and honour, they laughed over the Parisian levity with the utmost good humour and surprise! The projector, however, felt it his duty to publish "The Pyramid Prospectus," and this furnished the public with the real name of the architect, which proved no joke to his honourable friend, who now began to entertain a very different view of it, and Père la Chaise became his hobby, and his hobby he is determined to ride, "come what come may," and thus determined, resolved he would sink the Pyramid at a blow; and such a blow as is rarely, it is to be hoped, to be found in the history of such friendships! He proposed, as the last act of kindness to his unsuspecting friend, that he should transfer the whole force of his support to him (the honourable gentleman's) chambers, that he might advocate the cause, and teach the assembled party the value of The Pyramid which now began to be talked of to his confusion. So that with one pesti-

lental breath, and by the single word—*impracticable*—he might at length damn “the work of genius,” and the midnight labour of years, with one withering blast! That he did so attempt who will endeavour to deny?—(Vide the *Père la Chaise Prospectus*.)

The above proceeding was, doubtless, enough to astound the boldest projector, who now writhing under his wound, and disgusted with the world's deceit, nearly sunk into a state of fatal stupor. He, however, rose above the shock, looked upon its depravity with pity rather than contempt, but for security-sake requested permission to deposit his plans of the Pyramid in his Majesty's Office of Works; and we shall now show how graciously they have been received by the Surveyor-General, who was pleased to send the following acknowledgment, with his unbiassed judgment, which will speak for itself:—

“Office of Works, 14 April, 1830.

“SIR,—I have to acknowledge, with many thanks, the receipt of your obliging letter, with the accompanying plans of your very valuable and scientific design for a general metropolitan cemetery, which does great credit to your professional talents, and with my best wishes for your success in your great and arduous undertaking,

“I have the honour to be, Sir,

“Your most obedient servant,

(Signed) “B. C. STEPHENSON.

“To Thomas Willson, Esq.  
&c. &c. &c.”

The foregoing letter, with several others of the same encouraging nature from some of the most eminent scientific individuals in the kingdom, which admit “that the Pyramid has the exclusive property of creating hundreds of acres out of a void space, and that no other plan can be invented with the like advantages, that it is also the most complete and comprehensive for the purpose required, and that no other plan can compete with it for its numerous and original qualities—that, in fine, it is the only one commensurate with the end proposed,” &c. These testimonials had the good effect of cheering up the spirits of the projector, and emboldened him to meet his honourable friend in the field of argument. He addressed him publicly at the meeting at Freemasons' Tavern, in condemnation of servilely copying the French, in the *Père la Chaise* scheme, and without deigning to think of his treacherous wound (fearing to injure a good cause), he checked every emotion of his aggrieved soul, and even offered his support for the general benefit—he moreover purchased five shares, in order to qualify himself to be a member of the committee—and, how has he been treated for his liberality and public spirit?

It is only a few days ago that the honourable gentleman (still smiling in the confidence of his proffered friendship) called at the Pyramid Office, and made the extraordinary proposal of a bribe to the projector, “if he would only descend further to qualify himself for the committee, by renouncing his Pyramid, and give the pledge of his word to support the vanity of the *Père la Chaise* hobby, through thick and thin, to the exclusion of every other plan, he would then confer office upon him, and have him on his committee forthwith; for (contingued he) as long as your Pyramid is before the public, it distracts our hopes, retards our progress, and prevents our receiving subscriptions, (which are of the utmost consequence to the honourable treasurer!) Write me, I beseech you, that you consent to my proposal, and you shall have my friendship for ever—adieu.” He instantly disappeared, like the bursting of a bubble! Adieu! aye, for ever; his friendship! what an insult! further qualification! a bribe too for dishonour! Surely as the projector has been duped of his deposit (12*l.* 10*s.*), he has doubly a right to demand restitution. These were the natural feelings of the insulted author of the Pyramid; and he appeals with confidence to an enlightened public to examine well the plan of the General Cemetery which they are about to adopt, before they venture upon subscriptions that may otherwise be applied contrary to their wishes, without regard to their true interests, and derogatory to the honour of the country.

From this statement the public will be assisted to form a correct judgment of the kind of man they have to deal with in the projecting barrister, who has travelled out of his record to obtain emoluments and fame. He is deliberately accused of duplicity and meanness, of cajoling and deceit; he has betrayed confidence, and under the mask of friendship deprived a deserving and laborious individual of all that he had ever hoped to enjoy, as the reward of talents devoted to the public. It remains to be seen whether that public will allow itself to be duped by pretensions, unsupported by a single claim to its patronage,—whether it will be satisfied with a *Père la Chaise*—a servile imitation of what requires no ingenuity to carry it into effect, which is a mere temporary expedient to meet a necessity, which accumulates with every succeeding generation, and which is designed to supersede a great national undertaking, which combines within itself a novel and permanent monument of metropolitan wealth and magnificence, commensurate with the growing demands of a dense and increasing population. Must the Pyramid sink to prepare the way for a scheme without genius, and a pro-

jector without veracity? who has forfeited every claim to confidence by a dishonourable breach of unsought and proffered friendship to him whom he first betrayed and then insulted? These are grave accusations: the worst part of them is that they are true, and cannot be controverted by the miserable delinquent they thus publicly and fearlessly denounce.

## CLINICAL LECTURES

DELIVERED AT

*'St. Bartholomew's Hospital,*

BY MR. LAWRENCE,

*Friday, Nov. 5, 1830.*

### PHLEGMONOUS ERYSIPELAS.

GENTLEMEN,—The severe case of phlegmonous erysipelas in Darker's Ward, to which I directed your attention at the last lecture, has since terminated fatally. I regret much that I cannot give you any account of the morbid appearances which the disease may have produced, in consequence of the examination of the body having been prevented by the friends of the deceased. The case was altogether one of unusual severity, and it would have been interesting to ascertain the state of the internal organs, whether they were sound, or whether there existed in them any morbid condition which might have given rise to a new state of the general system, and might, in some degree, have explained the occurrence, and the serious extent of the local disease. The nature of the case was moreover interesting, both in a pathological and practical point of view; pathological, since it afforded us as severe an example as I have ever witnessed of inflammation and mortification of the cellular tissue of the upper arm to at least two-thirds of its extent, and which, had the patient lived some time longer, would have induced sloughing of the integuments to a corresponding degree; practical, since it afforded a salutary caution with respect to the necessity of treating this disease efficiently from the first; and it shows also the danger that arises from inappropriate or inadequate treatment. In this patient, from the first, the disease must have been severe, yet the necessary treatment was not adopted, and he was six days in the Fever Hospital before I saw him.

When I mentioned, on the preceding evening, the mode of treating this disease by incisions, I did not mean that they should be limited in their application to that period in which suppuration and mortification have already taken place. On the contrary, they

are of the utmost utility in a far earlier stage, for they prevent the occurrence of the suppuration and mortification of the cellular membrane, which would otherwise supervene. When these have occurred, this treatment is above all others the best calculated to limit the further progress of the disease, and to relieve the congestion and tension of the inflamed parts. From the incisions in the present instance, the patient derived all the relief which could have been expected; the pain was diminished, and the general irritation lessened, but the disease had proceeded too far before they were performed.

### SIMPLE ERYSIPELAS, FOLLOWED BY METASTASIS.

The patient Robinson, in Faith's Ward, also requires notice this evening. Since the last lecture she went on fairly enough, as regards the inflammation, till to-day. A blister was applied above the inflamed parts, with a view to prevent its spreading towards the body, and this seemed to produce the desired effect. Subsequently, however, the inflammation has extended a little above the blister, but it soon stopped, and did not reach the groin. To-day the case has again become alarming, but from a different cause, from the sudden supervention of serious internal disease on the cessation of the external affection, or that which is technically called "metastasis." You will remember, that for the erysipelas she had been treated with considerable activity; in consequence of this depletion, the local inflammation has abated. She complained much of debility and exhaustion, and I ordered her the subcarbonate of ammonia and camphor mixture. Early to-day she complained of extreme pain in the chest, in the abdomen, and in the back, and her breathing became very much oppressed. She appeared in great distress, and in such general pain, that she could not precisely indicate the parts which were most affected; so that when I desired her to inspire deeply, she referred the pain which it created to her back. Her pulse was excessively rapid, and very feeble; her tongue inclined to be dry. Under all the circumstances, there is no doubt but that she has been seized with a violent pulmonary attack. As to the treatment, depletion has already been carried so far during the progress of the erysipelas, and she has been so enfeebled by the duration of that affection, that very active treatment cannot be instituted at present. I have directed twenty-four leeches to be applied to the chest, and a mixture containing tartar emetic to be taken occasionally, but I fear there is but little chance of a desirable termination of the disease.

## ANASARCA.

When you look, Gentlemen, to the catalogues of nosologists, and see the vast number of diseases they enumerate, the study of medicine appears of a most complicated nature; indeed it seems almost endless. Sauvages, for instance, has no fewer than one thousand three hundred *genera* of diseases. Now if you were to suppose that for each of these subdivisions a separate and distinct mode of practice were necessary, you might think the task an endless one, as I before observed; but when we examine into them practically, when we investigate the causes which have given rise to them, and the mode in which these causes operate, the matter is reduced to a much more simple bearing. Thus, though the forms of disease are very varied and greatly modified, yet the causes are comparatively few; they may act on the several divisions of the alimentary canal, or on the head, or on the circulation generally. Inflammation thus according to the organ it attacks, and many other circumstances, may assume various forms; yet, when we trace it back to its causes, we find that if they do not amount to absolute identity, yet they are in the closest degree alike. In this way bad habits and intemperate diet are known to operate as predisposing causes of disease, to produce an unusual state of the circulation, which may show itself in the end by inflammations in the thoracic viscera, the liver, the joints, in the form of gout, and numerous other modifications, and according to the constitution of the patient, apparently differing in nature, but in reality with respect to their causes.

Subcutaneous cellular effusion, Gentlemen, is one of the forms of disease originating in a disturbed state of the circulation, which irregular habits very frequently occasion, and an example of which we have now under consideration in a man named Simpson, about 30 years of age, on whose board "anasarca" is marked, and who was admitted on the 18th of October. In patients of thirty, Gentlemen, you usually do not expect to find anasarca as a symptom of general debility; but, on the contrary, the pulse will be usually firm, and the several symptoms indicative of a condition evidently depending on increased arterial action, and which is readily understood where irregular habits are acknowledged by the patient. This man, for instance, was a last and boot-maker, his employments were sedentary, kept him within doors, and, as is not unusual with persons of his class, he indulged himself in spirituous liquors, on the hypothesis, that the more strong drink he consumed, the more his strength should increase. He was very systematic, more-

over, in his mode of drinking, in which, by the way, he did not consider himself guilty of any excess; he had three pints of porter daily, in divided doses, half a pint in the morning, a pint at dinner, half a pint in the afternoon, and a pint at supper. I observed to him, "You take this quantity regularly?" "Oh yes, sir," he replied, "I keep very regularly to my times." Indeed he seemed to make a great merit of his systematic habits. (*Laughter.*) He took besides, he informed me, a small quantity of stronger materials now and then, a glass of gin and water occasionally, perhaps about seven glasses a week; and as he latterly felt himself getting weak, why to make himself stronger, he took an odd glass of wine. When I inquired as to his consumption of solids, he allowed, that except on extraordinary occasions, he seldom ate meat more than four times a day.

When you consider all this, Gentlemen, it will not appear very strange that a person of such habits should be liable to disease; accordingly he has been affected with rheumatism once before, about a year since, in this hospital. On the present occasion, about a fortnight since, he noticed his ankles tumid, the scrotum then became swollen; lastly, his face, and the subcutaneous cellular membrane generally, and for these symptoms he has been admitted now. I found the pulse full and strong, which facts, coupled with his previous mode of living, denoted the necessity of antiphlogistic treatment; he was accordingly bled to twelve ounces. I ordered him also active aperient medicines. On the first occasion, only four ounces of blood could be extracted from the arm, and he was cupped to 16 ounces. On the 21st October he was bled to 14 ounces, and the blood exhibited decidedly inflammatory characters. On the 25th, I directed him 2 grs. calomel, with a little opium every eighth hour, considering that depletion had already been carried far enough, and that the influence of the mercury would be sufficient to arrest any further inflammatory action, and at the same time to promote the absorption of the effused fluid. Under this treatment he rapidly improved, and, as far as the anasarca is concerned, may now be considered well.

A short time since I had a somewhat similar example of this affection in private practice, in the case of a gentleman about sixty years of age, of rather corpulent form; his aspect was full, and his face red. He was a gentleman who had recently retired from business, and was rather of free habits; his pulse was moreover full and strong, and when I saw him, his respiration was considerably accelerated by the exertion of coming to obtain my advice. I told him I should recommend the abstraction of blood, he

seemed greatly surprised. "Blood, sir," said he, "why I feel very weak." "I bleed you, sir," I rejoined, "in order to increase your strength." "Why, sir," he said, "my medical attendant has directed me to take strengthening things; but what appears to me strange is, that the more wine and spirits I drink, the weaker I become." I told the gentleman I did not wish him to believe me, if he preferred to obey the directions of any other practitioner; however, he eventually put himself under my care. I had him bled, gave him nitre and cream of tartar, with a little of the compound spirit of juniper; and as it is necessary to sacrifice a little to the habits of such persons, I allowed him a pint of porter every day. He returned to see me in a week; the blood had been sizzly; he had obeyed my directions; the serous effusion was removed from the legs, and in the course of a few days he was effectually relieved from all troublesome symptoms.

#### OPHTHALMIC INFLAMMATIONS.

There are two or three cases of inflammation affecting the various tissues of the eye which demand our notice at present. The first I will mention, is that of Sarah Dickson, in "Faith," ætat. 26, who was admitted on the 22nd October, with inflammation of the external tunics of the left eye, and you will see on her board a query affixed as to the existence of "iritis" also. The eye, she said, became first painful on the 16th October; she went to a medical person for advice, and had a lotion, which produced no relief. When admitted, there was evident inflammation both of the conjunctiva and sclerotic; there was a great deal of general disturbance, heat, feverishness, and headache; her rest was also disturbed by deep-seated pain in the eye. From this circumstance I was led to suspect internal inflammation; moreover her vision was dim, and on comparing both the irides, a manifest difference of colour could be perceived. Though the disease was but recent, yet the violent nature of the symptoms was well-marked, and in order to arrest the progress of an affection, which was serious as far as regarded the external parts, and suspicious as to the internal structures of the eye, I directed a pint of blood to be removed by cupping from the temple of the affected side. This evacuation was performed on the 22d October, and by the 25th she was completely well.

I must here observe, that in inflammatory affections of the eye, it is essentially necessary to use vigorous and effective measures from the commencement; you should not be content with the application of four or six leeches, and cooling washes, and then think the case will do well. Under such

useless treatment, it repeatedly happens, that the inflammation proceeds unabated, or even becomes aggravated. In my long experience, I have always observed the benefits attending active treatment in the early stages, and I have never known any evil to result from the depletory plan. I have no hesitation in saying, that if ineffective treatment had been continued in this case, the inflammation might have proceeded to the irreparable destruction of vision.

In the same ward, Gentlemen, there is a woman named Thomson, about 37 years of age, affected with chronic inflammation of the conjunctiva; her eyelids are also red; her nose, by the bye, is of the same complexion. On admission on the 1st October, the affection did not appear very serious, and no very active medicines were prescribed. On the 6th, however, 24 leeches were applied; on the 11th, she was cupped, to 16 ounces. The symptoms were still not at all diminished; and on further examination of the eyes, there appeared something like sclerotic inflammation, with some minute ulcers on the conjunctiva; the eyelids, too, were redder at their margins than they were before observed. She was cupped again to 16 ounces; on the 13th she was leeches, and again on the 15th; on the 18th leeches were again directed, but at her own request cupping was substituted, as she stated she felt herself much more relieved by the use of this evacuation. This, Gentlemen, may appear very large depletion, but it was strictly proportioned to the necessities of the disease, and the patient's own sense of the benefits it conferred. She was accordingly in the end entirely relieved.

In the same ward there is another patient, Mary Jones, aged 18, affected with strumous ophthalmia and nebulous opacities of the cornea; she had suffered repeated attacks of inflammation of the eye, which had induced the nebulous opacities occupying the central cornea. It is the nature of strumous affections, Gentlemen, to recur frequently, though apparently removed, and, in the present instance, the attack was rather severe; she suffered great intolerance of light; there was considerable external redness of the conjunctivæ, and fasciculi of congested vessels were seen running over the cornea, and terminating in the opacities which former inflammations had produced. Great intolerance of light I consider to be one of the most striking characteristics of the strumous inflammation. In this instance, although the patient was quite willing to open the eye and submit it to the trial, she could not bear the light for an instant. It is a very common doctrine, that scrofulous affections are diseases of debility, and that in their treatment, the object should consequently be not to depress, but to strengthen.

Certainly there are not a few cases of strumous ophthalmia, which, to a certain extent, sustain this opinion: for example, in the children of the poor, who are continually exposed to the depressing causes of insufficient or noxious food, and the want of necessary clothing; but, on the other hand, there are many instances of the disease in which, at the same time, the causes are different, and an opposite treatment must be observed.

In the present case, besides the ophthalmic affection, it appeared that the menses had been absent for three months; this circumstance, coupled with a rather prominent, respectable state of the abdomen, induced me to inquire whether there might not be some natural cause or other to account for the suppression. The sister also assisted in the investigation, but it turned out that the suspicions were erroneous; the suppression, nevertheless, was concerned in the support of the ophthalmic disease, and it accordingly received its share of attention. On the 23rd she was bled; on the 24th, twelve leeches were applied, with fomentations, and she was placed on milk diet. On the 27th, twelve leeches were again applied, and she was directed to rub in the tartar emetic ointment behind the ears and the back of the neck. To this point I wish to direct your particular attention. In the treatment of scrofulous inflammations, you will often find the counter-irritant practice of special service. In the natural course of these diseases, you find that, on the retrocession of one inflammation, another appears; that, when a second part becomes affected, the first is relieved. The mode of operation by counter-irritation, is thus sufficiently explained.

Besides the above treatment, this patient has been repeatedly leeches, and subsequently twice cupped; she has also used active aperient medicines. These means have been followed by the return of the menstrual discharge, soon after which the pain and redness of the eyes gradually abated, and she may now be considered quite well. You here see that the suppression of the menstrual secretion was connected with the ophthalmic disease.

#### FRACTURED PATELLA.

In Rahere, Gentlemen, there is a patient about fifty years of age, admitted on the 15th of October with a fractured patella. I merely mention the case, in order to point out that, in many instances of fractures, simple attention to position will accomplish the desired object, without the necessity of employing bandages, or any other mechanical apparatus. In this example the knee was kept perfectly straight, and the thigh bent upon the pelvis; and thus the muscles,

which act on the patella, were completely relaxed, and the broken parts of the bone so closely approximated, that the tip of the fore-finger could not be insinuated into the separation. Indeed they could not be brought nearer by the hands, consequently bandages were useless. In such a case it would be extremely difficult to apply a bandage so tightly, that it would bring the fractured parts together, without slipping over their ends, and thus defeating the object it was applied to promote. In this case, as there was a slight tendency to inflammation of the surrounding soft parts, leeches and cupping-glasses were applied to the knee, and a saturnine lotion was also employed.

While mentioning this case, I may remind you that fractures of the patella, in a great majority of cases, take place as the result of muscular action; I do not mean to say that this force directly drags the patella in two, but the fracture takes place in consequence of a person slipping forward, and the instant occurrence of a violent involuntary effort of the extensor muscles of the thigh towards replacing the body in the erect position; the patella is thus dragged over the anterior surface of the femur, and snapped across, as a stick would be broken over the edge of this table: the bone thus yields to a kind of pulley action, and the patient falls to the ground in consequence of the fracture of the patella; it is not that the patella has been broken by the fall.

In the same ward there are some other cases which illustrate reunion, part of the treatment of fracture, by mere attention to position, without the use of splints.

#### FRACTURE OF THE LEG.

A patient was admitted with compound fracture on the 27th of October; he is a man about twenty-eight years old; he fell from a scaffold at a moderate height, and a fracture took place without any great violence. There was a simple fracture of the fibula, and compound fracture of the tibia, and the bone protruded through a wound about half an inch in length; the protruded end was replaced, and as the external opening was so small, I was induced to try to heal it at once, and thus convert the compound into a simple fracture. The limb was placed in a fracture-box, two sides and the end of which are moveable, and lined with soft cushions; and thus the limb was readily placed in the desired position, and retained there with the necessary degree of force, and without inconvenience. A bit of lint dipped in blood was placed on the wound, and it was left thus for a few days, when the wound became red and inflamed. In accordance with the suggestion of Mr. Wood, the intelligent house-surgeon, I caused ice to be applied to the irritated

parts, a practice which he had known to be employed with benefit in the hospitals at Berlin. In compound fractures, it is from the state of the soft parts, from the effects of inflammation in them, that danger is usually to be apprehended; if therefore we can prevent its occurrence, we shall do much to secure a favourable termination even in the worst cases; and I think that the ice-plan may be adopted with great advantage even in cases of simple fracture. In this case it was applied two days, and completely with the desired effect; the inflammation has entirely abated, the slight swelling which had arisen has disappeared, and the limb is now of its natural size. There is now no reason to apprehend an unfavourable turn in the progress of this case.

#### SYPHILIS.

Mr. Lawrence next made a few remarks on the case of a young woman who had been admitted on the 21st of October with a syphilitic affection of rather formidable appearance, consisting of sloughy phagedenic sores at the entrance of the vagina; her habit of living had been full, and her disease was communicated by a waiter in the same tavern, and was not the result of promiscuous prostitution; her pulse was quick and full, tongue white, and there was much constitutional disturbance.

If you could lay aside the idea of a specific affection in this case, said Mr. Lawrence, and consider that you had to treat three considerable and highly-inflamed ulcers, it is pretty clear that mercury is not the remedy you would employ. I therefore directed her to be bled to sixteen ounces, and to have four grains of calomel and twenty of jalap; the blood was, as I expected, of an inflammatory character, cupped and buffed; poultices were applied to the inflamed parts. This treatment was persevered in, and to-day, the 5th of November, Guy Fawkes' day, all her symptoms are abated, and she is nearly well.

#### ST. THOMAS'S HOSPITAL.

#### CLINICAL LECTURE

DELIVERED BY

DR. ELLIOTSON,

Nov. 1, 1830.

I AM sorry, Gentlemen, that I was prevented having the pleasure of meeting you on Monday last. I was sent for to a considerable distance from town during the preceding Saturday night, and was unable to return before Monday morning, when I

was too much fatigued for business, and was compelled to retire to rest. Had I met you on Monday, I should have stated that only three patients were admitted on Thursday the 21st, all of whom were females; one of these was a case of continued fever, one a case of apoplexy, and one a case of rheumatism. I should also have had to state, that this week also no patients had died in my wards, consequently I could have shown you no specimens of morbid anatomy.

On Thursday last, the 28th, there were admitted among the women a case of ascites and diseased liver, a case of convulsions occurring in a female who had lately lain in, apparently from hæmorrhage (the case might be called one of hæmorrhagic puerperal convulsions), a case of fever, and a case of rheumatism. Among the men was a case of inflammation of the spine, which might have been mistaken for rheumatism; two cases of rheumatism, and what is very singular, from its admission just at this moment, a case illustrative of the ill effects resulting from excessive loss of blood, for it is similar at least in its causes to that of the woman. With respect to the presentations among those who had been admitted since the commencement of the month, I may mention that, of female patients, there has gone out the case of hysteria, the two cases of peritonitis, and the case of apparent tumour in the abdomen. Among the men—the case of rheumatism of the chest, of which I spoke in my last, and the two cases of fever. These cases of fever were exceedingly slight, as are most of those which are admitted into the hospital; they required nothing more than local bleeding from the head; the pit of the stomach, and other parts of the abdomen; tepid ablution, a moderate exhibition of aperients, and an equally moderate exhibition of mercury, though some cases of this kind would probably do nearly as well without mercury. The case of hysteria was successfully treated by bleeding (for it was characterised by great pain of the head and loins) and mercury. I mentioned that there was a case apparently of tumour of the abdomen. In this instance I felt a moveable hard tumour upon the right side of the umbilicus; in other respects the woman appeared to be in perfect health; by purging her an immense quantity of hard fæces was brought away, and on my second visit I could discover no enlargement, so that the tumour consisted of nothing but a collection of hardened fæces; some degree of pain was afterwards complained of, but that subsequently disappeared, or, at any rate, she thought proper to complain of it no longer, after leeches and a blister had been applied. The tumour appeared to have arisen merely from having permitted the bowels to get into a costive

## DR. ELLIOTSON ON LOSS OF BLOOD.

state. This shows the necessity of a careful investigation before forming an opinion on any case, for the present might at first really have appeared to be a disease of considerable danger: by the removal of the faces, however, the case was fully cleared up. The two cases of peritonitis which I mentioned as having been presented, were cured by general and local bleeding, mercury, and low diet.

### ILL-EFFECTS ARISING FROM EXCESSIVE LOSS OF BLOOD.

The cases which I purpose to introduce to your notice this morning, are those of the man and the woman who appeared to be labouring under the ill effects of excessive loss of blood. The case of the man was this:—

Abraham Dick, ætat. 39, a bargeman, was cupped at the back of the neck, and between the shoulders, on the 21st of last month, in consequence of violent pains of the head, and epistaxis, experienced during the preceding fortnight. He experienced great relief from the bleeding. During a fit of vomiting, which came on the day after the cupping had been performed, the scarifications began to bleed afresh in spite of every effort to stop the hæmorrhage, and a very large quantity of blood was lost. In consequence of this he was brought to the hospital on the 26th. There can be no question about the propriety of the cupping; for, at the time of the operation, he had vertigo, drowsiness, and violent pain of the head, and all these symptoms the cupping relieved; it was therefore to the subsequent hæmorrhage the mischief is to be ascribed. It appeared that, besides the original affection, he had been subject to fits of vomiting, and likewise to a slight cough, but particularly to vomiting, which, most likely, depended on the state of the head. The vomiting, however, after bleeding, got worse; every thing he took was rejected from the stomach, and the act of throwing up its contents was attended with considerable pain. The appearance of his countenance corresponded with the effect usually produced by loss of blood; he was of a pale straw colour; he complained of great debility, and of inability to stand or walk; his pulse was low and feeble, and he complained of great thirst, a circumstance which is common, when there has been any great loss of the fluids, either by sweating, purging, great flow of urine, or bloodletting. He had now no pain of the head, but on sitting up, or moving about, there was giddiness; this, however, passed off the moment he lay down; he was subject also to chilliness, and sometimes almost fainted; he was likewise restless and anxious, and when I first saw him his hands were tremulous. On

feeling his pulse, first while he was lying, and afterwards when sitting up, I that there was a considerable difference: the moment he sat up it became weak irregular, but as soon as he again lay do it became more full and regular. I repeated this experiment, and obtained the same result, but on a third trial the change was not observable.

He came into the hospital after I had made my visit on the evening of October 26, and was then very properly ordered laudanum and good nourishment. He took thirty minims of tincture of opium, and was ordered two pints of beef-tea, and two of milk. The case was not one of great intensity, but was decidedly one in which the ill-effects arose from the loss of blood. He was likewise ordered iron, in the form of the subcarbonate; certainly one of the best agents in restoring the system when an abundance of blood has been lost. It will not, however, act quickly, so that if you want to obtain an immediate effect, this would not be the proper remedy to adopt. As in the present case, however, there was no immediate urgency, it was very proper to administer the iron, any immediate benefit being rather intended to be derived from the opium. At the time of his admission the scarifications were bleeding, but the flow was arrested by pressure.

On the 27th it was found that he still vomited, that all his food was rejected, and that he had great pain in the scrobiculus cordis at the moment of vomiting, though at no other time. The pulse was said to be 88 and full, and there was thirst. At night he appeared to revive.

At four o'clock the next morning, the 28th, he coughed, and the hæmorrhage was renewed to such a degree, that it became necessary to call the dresser, who again stopped the bleeding by pressure. At noon, the vomiting being no better, half a grain of opium was prescribed in substance, in room of the tincture, which had been rejected by the stomach. The same quantity of solid opium was ordered to be given every four hours. By the first dose the vomiting was in some measure checked, and the opium was no longer rejected. He slept during that night, and it appeared on the following day that he had vomited only four times during the twenty-four hours, and that then the vomiting was only produced on coughing or taking food, a circumstance which is very common where persons have been subject to severe vomiting. There was less pain too, on these occasions, and less tenderness in the epigastric region. It appeared, therefore, that there was rather a morbid irritability than an inflammatory condition of the stomach. He still complained of giddiness, but his headach was now slight; his pulse

## DR. ELLIOTSON ON LOSS OF BLOOD.

Full, and rather sharp, and his hands all tremulous.

On the 29th he had slept better, and had vomited only once, thus evincing the propriety of the treatment. If the vomiting had been supposed to arise from an inflammatory condition, and there had been considerable and constant tenderness on pressure; leeches would have been indicated, but the application of these would only have made him worse, whereas the administration of opium relieved him, as regarded the vomiting. On the 28th, as he complained of want of sleep, I substituted a full dose for the smaller ones, giving him three grains at once at bed-time, and I allowed him four ounces of wine in the twenty-four hours. A clyster was required on the 29th. I found that he had vomited but once, had slept better, and felt stronger. The three grains of opium, the wine, strong beef-tea, milk, and iron, were ordered to be continued daily.

On the 30th the report is, that he had been rather restless, and complained a good deal of giddiness; his bowels had been opened by the clyster, and from this he felt better; he had vomited only four times in the course of the last twenty-four hours, and that was when he had coughed; the pulse was softer.

On the 31st he had suffered great restlessness and anxiety, and had passed a very bad night. He had also wandered in his conversation, and had attempted to leave his bed. At two o'clock his nose began to bleed, and continued to bleed at intervals until six in the morning, though measures were used to stop the flow; he did not, however, lose altogether more than two or three ounces of blood. At midnight his pulse was very variable; at one time it seemed to be rather full and compressible, and at another it was almost indistinct. The sister of the ward said, that fits of palpitation of the heart came on so violently, as to cause the bed to shake, and that during his sleep his breathing was performed with a great noise, like that of croup. I presume it was stertorous. He was given half a drachm of liquor ammoniæ subcarbonatis every three hours, and three ounces of brandy at intervals; by this he was much relieved, and towards morning was considerably better, but on visiting him on Sunday afternoon at four o'clock, his countenance was still very anxious, and he wandered in his conversation; there was also rather more tremor in his hands, and the pulse was sharp and variable, sometimes being a mere thread. At nine o'clock in the evening he was lying perfectly insensible; his eyes were fixed, his pupils contracted, his pulse was slow and feeble, and respiration was

taking place at long intervals, and at half past ten o'clock he died.

In this case the original affection was in the head; at least that was the only affection of which, I understand, he had complained, and for which he had been treated; the excessive loss of blood produced drowsiness, giddiness, and, in like manner with the previous fulness, pain of the head. It might have been supposed that the giddiness and headach under which he was suffering on admission, only arose from the violence of the original affection of the head, but the sharpness and feebleness of the pulse, the blanched appearance, the faintness, and the knowledge of the previous excessive loss of blood, declared the true nature of the case. When I saw him last he was doing well; and the change for the worse and his death happened between my visits.

The other case of a similar nature, which I shall mention, occurred among the women, and here the affection of the head, arising from loss of blood, proceeded to actual convulsions. Considerable difficulty must have been experienced on admission in ascertaining the nature of this case. The woman was nineteen years of age, and had had two children; she was brought to the hospital on Thursday last in a state of insensibility and convulsions. It appeared that she had been delivered of a child rather more than three weeks before. The convulsions were of an irregular character, with insensibility and stertorous breathing. She was seen and prescribed for; after my visit, sixteen ounces of blood were taken from the back of her neck, and fifteen grains of comp. ext. col. were administered, together with an injection; also a lotion was applied to her head. No information was given as to the history of the case; all that the friends said was, that she had that morning been seized with convulsions and became insensible. The natural conclusion certainly was, that this was a case of determination of blood to the head, and the proper indication of cure was, to take blood from that part. Further, the head was hot; and had she been prescribed for by myself, I think it is more than likely I should have treated her in the same way. Her pulse was full. Three weeks had elapsed since her confinement; the head was hot; she was in a state of insensibility and convulsions, and the breathing was stertorous, and had she died that day without being cupped, without the abstraction of blood from the head—I think, had I been the person on whom this omission depended, I should have blamed myself. But it turned out, when more of her history was known, that the propriety of the treatment was doubtful. When I first

saw her on the following morning she was in a state of convulsion, moaning, with stupor, and stertorous breathing. Luckily for me, the gentleman who had attended her in her confinement had come to the hospital to see her, and he then informed me that she had experienced excessive flooding in her labour, that it had been necessary to turn the child, and that at the time of this hæmorrhage, convulsions had come on—convulsions similar to those which were now present. He also told me, that although three weeks had elapsed, she had never once regained her colour, and she certainly still was of a deadly white. But notwithstanding this appearance, had I seen her the day before, I should have considered her as a person in an epileptic state, with great stupor, and a tendency to apoplexy; I should have ascribed the paleness to the epilepsy, in which I have often seen persons of a ghastly paleness. I found her pulse full, and I should have thought on first feeling it, had I not been informed by this gentleman that she had had previous flooding, and had I not noticed that, besides the fulness, the pulse had a peculiar sharpness, and it justified me in taking blood, at least, from the head; it certainly possessed a hæmorrhagic sharpness, but yet it was also so full, that I was induced to hesitate for a moment, and consider still whether I ought not to apply leeches to the head. It happened, however, that while I was standing at the bedside, considering the nature of her case, and taking all the circumstances connected with it into consideration, the character of the pulse altered; it actually became a little irregular and decidedly weaker, and I then very soon clearly saw, that the case was one of exhaustion—of convulsions from loss of blood.

The treatment to be adopted was at once indicated, namely, to give stimuli and nourishment. I administered at first twenty minims of liquor ammoniæ in camphor mixture, and on watching its effects I perceived that it scarcely even stimulated her. I repeated the dose in about twenty minutes, with half a drachm of tincture of opium. I waited perhaps twenty minutes more, and during the whole of this time the pulse regularly sank, becoming weaker and weaker, and gradually losing its sharpness; she became colder, and so great a difficulty of swallowing supervened, that nothing could be taken into the mouth. I sent for the stomach-pump, but as the stomach is very weak in these cases, and frequently becomes so irritable as to reject nourishment, and render the subsequent administration of medicine and other stimulants fruitless, I attempted to nourish her *per rectum*; a quantity of strong beef-tea, with four eggs beat up in it, was accordingly thrown up.

The whole, however, was immediately rejected; it was scarcely thrown in before it was discharged. Under these circumstances I at once employed the stomach-pump, and got some brandy, wine, and more laudanum, into the stomach. I remained in the hospital some few hours, and in the course of that time a considerable quantity of brandy was got down. Still she regularly sank, none of the stimulants making any impression upon her, except in one instance, when, for a few minutes, the pulse rallied, though in a very slight degree. With that exception, the decline of life was steady and progressive; the breathing became slower by degrees, and at about four o'clock in the afternoon she expired.

I am sorry to say that the body of the woman was not opened. The friends took it away, so that I had no opportunity of examining the state of the internal organs.

The body of the man was examined by the gentleman who is my clinical assistant, and the internal parts, particularly the brain and its membranes, proved extremely pale and exsanguineous, and the brain unusually soft, but no further disease was anywhere discovered.

I need not say that convulsions are very common in the puerperal state. The convulsions of this woman were exactly of the puerperal character. In the convulsions of lying-in women, there are the general symptoms of epilepsy; but in these there is frequently the stertorous breathing of apoplexy, though no apoplexy is present. The patients are either perfectly comatose, the same as apoplectic persons, or between the convulsions they revive, as if awaking from slumber, and completely regain their senses. It is said that patients generally close their teeth, withdraw the under lip, and make a hisping noise. This is described by Denman in his great work on midwifery. I do not know that, in the present case, there was this noise, but she had so far symptoms of epilepsy as that she was convulsed and insensible, and inasmuch as the state of stupor was constant and lasting, and the breathing decidedly stertorous; she had symptoms of apoplexy. Hence she presented every mark of puerperal convulsions, except that the convulsions occurred three weeks after delivery, which is rather unusual. But whether it might properly be deemed a case of puerperal convulsions or not, and considering that there was no knowledge of any hæmorrhage having occurred, the state of the pulse appeared to justify the bleeding that was resorted to by those who prescribed for her the day before.

One effect of excessive loss of blood is great stupor, a consequence which is well known, though I cannot tell how long the

observation has been made. You will also find it stated in obstetric books, both English and French, that loss of blood from great flooding leaves intense pain of the head, and intense giddiness, affections which are not to be removed by cupping, but by stimulants. The existence of intense pain in the head is particularly dwelt on, and you will also find it mentioned that there are many attending nervous symptoms; that there is debility, sinking at the pit of the stomach, frequent vomiting, and palpitations of the heart sufficiently violent to shake the bed. It has always been known that sudden profuse hæmorrhage frequently produces convulsions. I have known persons, on the one hand, die from hæmorrhage, in whom the convulsions before death have been extremely violent, and other instances, in which symptoms of extreme and rapid exhaustion have been produced, and the patient has died without convulsions. I recollect a case of a man who died from hæmorrhage of the thigh. The surgeon having made a deep incision near the groin, because the extremity was swelled—was in a state of phlegmasia dolens—wounded the great vessels of the part; a basin or two of blood were soon lost, and death ensued in two hours, accompanied by restlessness and convulsions. It has also been long known, not only that there is this violent pain in the head, this giddiness and palpitation, but also that stimulants and tonics are the proper medicines for this state, and that bleeding is injurious. When I was studying books on midwifery, I recollect reading that this state was not to be relieved by leeches, but by Peruvian bark. Notwithstanding our long acquaintance with these facts, however, the profession are much indebted to a gentleman who has lately brought this subject more particularly before them, and who has described with great accuracy the effects arising from great loss of blood. I allude to Dr. Marshall Hall. In a paper contained in the thirteenth volume of the *Medico-Chirurgical Transactions*, part I., you will find some very valuable information on this point. When I was a pupil the facts now stated were familiar to me, and formed the subject both of instruction and conversation; but the importance of the affection, and its frequency were by no means dwelt upon, and on that account I think the profession much indebted to Dr. Hall for impressing on them how frequently all these symptoms arise from mere loss of blood, instead of inflammation, and for particularly pointing out the liability of some of them to be mistaken for the effects of inflammation. You will find it stated by him that there is “forcible beating of the pulse, of the carotids, and of the heart, accompanied by a sense of throbbing in the head, of palpi-

tion of the heart, and eventually, perhaps, of beating or throbbing in the scrobiculus cordis, and in the course of the aorta. This state of reaction is augmented occasionally by a turbulent dream, mental agitation, or bodily exertion. At other times it is modified by a temporary faintness or syncope. In the more exquisite cases of excessive reaction, the symptoms are seen more strongly marked. The beating of the temples is accompanied by a throbbing pain of the head, and the energies and sensibilities of the brain are morbidly augmented. Sometimes there is intolerance of light, but still more frequently intolerance of noise and disturbances of any kind, requiring stillness to be strictly enjoined—the knockers to be tied, and straw to be strowed along the pavement. The sleep is agitated and disturbed by fearful dreams, and the patient is liable to awake in a state of great hurry of mind, sometimes almost approaching to delirium. In some this is slight, but occasionally severe, and even continued. More frequently there are great noises in the head, as of singing, of crackers, of a storm, or of a cataract, and in some instances flashes of light are seen. Sometimes there is a sense of great pressure or tightness in one part or round the head, as if the skull were pressed by an iron nail, or bound by an iron hoop.”—You are well aware that we see these very symptoms arising every day from fulness of the head, and that they are every day cured by bleeding, purging, and starvation—“The action of the heart and arteries, Dr. Hall proceeds, is morbidly increased, and there occur great palpitation, and visible throbbing of the carotids, and sometimes even of the abdominal aorta, augmented to a still greater degree by every hurry of mind or exertion of the body, by sudden noises, or hurried dreams and wakings. The patient is often greatly alarmed and impressed with the feeling of approaching dissolution. The pulse varies from 100 to 120 or 130, and is accompanied with a forcible jerk or bounding of the artery. The respiration is apt to be frequent and hurried, and attended with alternate panting and sighing, and in this state of exhaustion sudden dissolution has sometimes occurred.” Dr. Hall likewise mentions that among the very earliest symptoms, in these cases, there is “a rattle in respiration only to be heard on the most attentive listening. This crepitus gradually becomes more audible, and passes into slight rattling.” This I distinctly heard in the case of the woman before us.—“There is also oppression in the breathing, inducing acuteness of the nostrils, which are dilated below and drawn in above the lobes at each inspiration.”

Several cases are given by Dr. Hall illustrative of this description, and it is mention-

ed in them that stupor, stertorous breathing, and convulsions, are among the more intense effects.

Now I think it exceedingly probable that this woman was labouring simply under some of the effects of the great flooding which she had experienced three weeks before. You are not at all to be surprised at the distant effects which injurious circumstances will produce on the body; for you will recollect what I have before referred to, namely, the great length of time after which injury of the head will produce inflammation and organic disease. I know an instance of a gentleman now having hemiplegia of the right side of the body, in consequence of a *coup de soleil* received thirty-six years ago on the left half half of the head. The *coup de soleil* rendered him perfectly insensible for a long period. He was at that time living in a hot climate, and his life was endangered, and now the opposite side of his body has become paralytic. This is one of the longest periods of time at which I have known such an effect to take place. In an opposite state of the frame, however, where there is great exhaustion, you will also have ill effects at a later period of time after the original cause than you would imagine. Instances have been known where persons have been nearly starved to death, who, although they have appeared to improve after taking food, have, after a certain time, suddenly sunk. In cases of hæmorrhage the same thing is observed. Although you stop the hæmorrhage, although the patient takes nourishment, although, perhaps, you transfuse blood, yet, at a distant period, he may gradually and quickly sink; or, on making some little effort, he may suddenly expire. I have been told of an instance of a lady in whose case transfusion was performed, who died at the end of a week, while merely turning in bed. Now it is very possible that the present poor woman suffered so much from the flooding which took place in her labour, that particularly, perhaps for want of paying sufficient attention to herself, from not being sufficiently careful of her strength, or not taking proper nourishment, she fell suddenly at last into the state which I have described. This is very possible, and not at all contrary to what we frequently observe. If so, we must believe that such ill effects may arise from extensive loss of blood at the end of three weeks. That ill effects did remain is certain; for, as I told you, the gentleman who attended her informed me, that she had never since regained her colour, but remained as pale at the end of the three weeks, as she was at the time of the flooding. Besides, the symptoms under which she laboured were generally those which are well known to ensue upon loss of blood—vertigo, headach,

dulness of mind, palpitation, and all the varieties of nervous feelings, and, in a minor degree, these symptoms are well known to last for a considerable time.

Respecting the diagnosis in this state, it must be taken in a very great measure from the history of the patient; but that, with the paleness and the state of the pulse, enable us to make out the real state of things. The pulse in this case was, certainly, full enough to justify the trial of bleeding, the effect being of course watched as the blood flowed. It was indeed rather sharp, which is frequently the case after too great loss of blood has occurred, and this sharpness, with great compressibility, has been peculiarly called a hæmorrhagic pulse. It would seem that the heart, having so small a load of blood, and that blood being of morbid tenuity, the organ is able to act violently upon the fluid; whence the sharpness; while the reduction in the quantity and consistency of the blood, and the debility of the arteries, prevent the pulse from having any solidity. If the flooding had been known by the gentleman who prescribed for her on her admission, I have no doubt that the sharpness of the pulse would have been at once attributed to the proper circumstance; but without a history of the case, it is possible for the best practitioner to be deceived. When such symptoms as violent palpitations, convulsions, pain in the head, or giddiness, afford no clue to a knowledge of their origin, and you cannot ascertain whether they arise on the one hand from an inflammatory state or fullness, or from exhaustion or depletion on the other (the sharpness of the pulse being often calculated to deceive), the surest mode is to observe whether there is any appearance of great loss of blood having taken place, to examine the general powers of the patient, to get a full history of the case, and to give a close attention to the effects produced by such measures as are adopted; to notice whether the pulse improves or not on a small bleeding, or whether rather it is not improved by the cautious administration of stimuli. These inquiries may lead you to a just conclusion, though frequently you may be unable to see your way clearly, without a knowledge of the history of the case. I have no doubt that mistakes often occur, in consequence of the symptoms I have mentioned having arisen from excessive venesection, without the practitioner being aware of any excessive loss of the true nature of blood, and that a cure is attempted by still further depletion.

The proper treatment, in instances of derangement from excessive loss of blood, is to give nourishment, to give stimulants, and to administer opium. It is the custom of many practitioners in cases of excessive

bleeding, and indeed in every species of hæmorrhage, where a great deal of irritability, with excessive exhaustion, ensues, to give full doses of opium, and to repeat them every few hours, according to the effect produced. Ammonia too is exceedingly proper, as also are brandy and good nourishment. How far the dose requires to be increased, must depend upon your observation of the case. I believe Dr. Marshall Hall has published a book on the subject, since the paper I before alluded to, in which he speaks of the *treatment* as well as of the symptoms. I have not yet had time to read this work, but I have no doubt that it contains much more information on every part of the subject, than the paper in the *Medico-Chirurgical Transactions*, which you will find in the hospital library.

This state is very analogous to one which we sometimes observe in children, and that which occurs in adults labouring under delirium tremens. You will find it mentioned in practical works, that children are liable to all the signs of acute inflammation of the membranes of the brain, that is to say, of acute hydrocephalus; and yet you would be wrong if you treated the disease as hydrocephalus. You know that in hydrocephalus there is acute pain in the head, intolerance of light, squinting, and vomiting, and, afterwards, dilatation of the pupils, convulsions, and complete insensibility. Now these signs will take place more or less, though a child have no inflammation of the brain, and may all frequently be remedied, not by bleeding, but by giving ammonia and nourishment. You will find the subject spoken of by Dr. Gooch in a collection of papers which he published on different subjects, but particularly those connected with the diseases of women. You are to form a judgment, and to decide on the mode of treatment to be adopted, by observing that the pulse, although quick, is weak, that there is no force in it, and that the surface of the body is not flushed, as in common cases of acute hydrocephalus, but that the whole of the skin is loose and pale; if there be any flushing of the face it is only transient. Under these circumstances it is right to give a few drops of the liquor ammoniæ from time to time, and beef-tea, keeping the child warm. You will thus soon discover the true nature of the case. Indeed, if this treatment be not pursued, but the opposite plan be adopted, the child most certainly will die. There is also a variety of disease of this kind to which adults are liable, requiring similar treatment,—cases in which there are delirium and a rapid pulse, and in which bleeding would be followed by destruction; this disease is called “delirium tremens.” The patient talks rapidly on a variety of subjects, particularly on his own

affairs, and fancies that conspiracies are formed against him. There is not violent delirium, yet he talks rapidly and incoherently, and gets out of bed, though you may easily lead him back again; his delirium is not of that terrific kind which requires several persons to hold him. He is weak, is in a constant tremor, and his pulse is quick. In this state of things the eyes are not red, nor is there ever any striking pain of the head; if you bleed him you may make him worse, whereas if you give him a full dose of opium—from three to five grains of solid opium, or from sixty to eighty drops of tincture of opium, repeating the dose every few hours, according to its effects, and giving him good nourishment, the condition will frequently go off. It is to be remembered, that the mere circumstance of trembling is no proof that the delirium requires this mode of treatment. If the face be flushed, and the eyes red; the pulse full or hard, and the patient young, it would be destruction to give opium; bleeding is the proper course to pursue. You must not prescribe for the name of the disease, but for the state of the patient. I have seen cases of delirium tremens which required not opium, but bloodletting. You are to judge between the two by observing whether the pulse be weak, whether the delirium be of a violent nature, and whether the tongue be moist, for generally it is covered by a creamy sort of mucus; you must act according to the strength, the age, and the constitution of the patient, the presence or absence of pain in the head, and the redness, or natural condition of the eyes. These circumstances will generally lead you to form a correct opinion as to the practice to be adopted. You may arrange all these cases together: the headach and convulsion consequent on hæmorrhage, the various hydrocephalic symptoms connected with debility, and the weak form of delirium tremens. There is in delirium tremens a mere debility, with morbid irritability of the brain, which is to be subdued by narcotics, stimuli, and good nourishment. There is the same state in children, resembling, to an incautious observer, acute hydrocephalus,—an inflammatory complaint, where you have very much the same symptoms, but which are independent of inflammation, and arise from exhaustion. There is the state of which I am more particularly speaking in this lecture, arising from loss of blood, which is to be cured (if it can be remedied) not by bleeding but by stimuli, nourishment and opium, and sometimes by transfusion.

I saw this female but a few hours before her decease, but I despaired of her from the beginning. Cases of this kind are always to be considered exceedingly dangerous, because, however well they may be

going on, there is always a chance of the patient suddenly sinking. When I saw this woman she was sinking rapidly. The man, however, whose case I have given you, was going on exceedingly well on Friday, and he appeared still advancing towards convalescence, when I passed through the ward on Saturday. A fatal change, however, took place so rapidly from that time, that I never saw him again.

With regard to the employment of transfusion. Although I had no hope of doing good by this means, yet knowing the benefits that had arisen from it, I deemed it right to consider the propriety of giving the woman the chance of its advantages, and I therefore requested Mr. Green to see her with me, to consult upon the propriety of pouring fresh blood into her veins. When I was at her bed-side, however, she was sinking so rapidly, that it was almost out of the question to suppose that an addition of blood would be beneficial to her. Then, in the next place, from the heat and great affection of the head, and the suddenness with which the stupor at so great a length of time had come on, it was exceedingly probable, that besides the great exhaustion, there was some effusion into the head, or some extreme congestion. I was not certain of this being the case, but the suddenness with which the symptoms had appeared, and the length of period since the flooding, deterred it possible that the disease might not be altogether one of exhaustion only. Mr. Green considered that there was so little hope from transfusion, that it was not worth while to risk the credit of the operation, by the addition of one more case of failure, and I did not press it. I did not think it would have done any good, but it was right for us to consider whether it was proper or not.

#### CASE OF MALFORMATION OF THE PULMONARY ARTERY AND AORTA.

Although I have not the opportunity of showing you any of the morbid parts of these two cases (the patients having been removed from the hospital), I am anxious to present to you a rare case of malformation of the great blood-vessels of the heart, which occurred in the surgeons' ward. I was requested by Mr. Green, in August last, to see a patient of his, a young girl, who entered the hospital a few weeks before with difficulty of breathing and swelling of the legs. I believe it was on account of the latter affection that she was taken to the surgeons' ward. Mr. Green, under whose care she was, thought that an affection of the heart existed, and requested that she might be seen by me. On examination I could not satisfy myself that there was any of those

diseases of the heart which can ordinarily be known by auscultation, for several exist upon which auscultation throws no light. I found her lying in bed, with difficulty of breathing, and great blueness of the face and hands. These may arise merely from a great difficulty of respiration, or from any obstruction to the course of the blood. I had a woman in this hospital last year whose face was nearly black from congestion in chronic bronchitis, although there was no direct communication in the system between the currents of black and red blood. I examined the lungs of Mr. Green's patient to see if there was any disease there which would explain the blueness, but I found there was none. On listening to her heart I found that it beat violently, but I could not satisfy myself that she laboured under any disease of the organ; yet there was of course a reason for the blueness: it was evident there was some disease, but what it was I could not ascertain. Judging, however from the countenance, I was led to ask her whether she had been blue from her birth, to which she replied—"Yes, always more or less." My own conclusion was that she had a malformation of the heart, and that the blood communicated between the right and the left sides, without the intervention of the lungs. She died about a fortnight ago, and on inspection a very rare malformation was found,—so rare, indeed, that I do not recollect ever having read of a similar case. I have examined several works since, but I can find no account of one like it. It presents an instance of an aperture between the pulmonary artery and the aorta. It does not appear that the ductus arteriosus is open, so as to present a communication by that means; but between the two vessels, at the point where they lie in contact, there is a small opening, so that by putting the finger either into the pulmonary artery or the aorta, it may be seen from the other vessel. On the table there are a great variety of specimens of malformation of the heart, but no case similar to the one I now show you. The pulmonary artery and aorta sometimes communicate after birth by the continuance of the ductus arteriosus; but in the present case there is no duct but a mere aperture. In the specimen I now exhibit there is a communication between the pulmonary artery and the aorta; the history of the case is not known, the parts having been found in a body in the dissecting room. An aneurism had existed in either the aorta or pulmonary artery, most probably in the aorta, and had burst into the other vessel, so that a communication was established between the two. You will find the best information on the subject of malformation of the heart in Mr. Burns' work on Diseases of the Heart, and Dr. Farre's Pathological Re-

searches, of which the first part, relating to malformations of the heart, is published. The preparations from which Dr. Farre has made his engraving belong now to this hospital, and are those before you. To produce such symptoms as appeared in this patient, there must have been a communication between the blood of the right and left cavities of the heart, or between the great veins and the great arteries, without the intervention of the lung. The symptoms are called the "blue disease," or "*morbus cœruleus*," or, if we prefer Greek to Latin or English, "*cyanosis*." The patient is more or less blue, especially the cheeks, and the extreme parts; he is cold, generally has dyspœa, and some degree of cough, and at length dropsy and dilatation or hypertrophy of the heart ensue. These symptoms, however, do not always occur when there is a communication between the two sides of the heart. I recollect opening a lady who died of rupture of the stomach, but who was never blue, although there was a free communication between the right and left auricles, by the existence of the *foramen ovale*: for in truth the blood never got mixed, and simply for this reason, that the connexion was valvular, and when each ventricle was filled, the two leaves were laid against each other, and the opening closed precisely in the same manner as the bladder, when distended, prevents a regurgitation into the ureters. This is observed by Bichat in his work upon Life and Death, and likewise in his General Anatomy. The presence of the *foramen ovale* does not necessarily imply a communication between the auricles when they are distended. This open state is certainly not very uncommon, but yet it is not so common as some people imagine. The mischief in malformation of the heart depends in a great measure upon another circumstance, namely, whether, when there is a communication between the right side and the left of the heart; the right side, or the pulmonary artery, is smaller than it ought to be, or not. If the right side be below its natural proportion to the left, or the pulmonary artery too small, then, if from any malformation, a quantity of black blood can escape, it will go at once very freely to the left side.

Among the preparations which I will demonstrate after lecture, you will see a remarkable instance of the pulmonary artery forming the descending aorta, and the aorta going no further than to give off the innominate, and the left carotid and subclavian, all the rest of the body being supplied by the pulmonary artery.

## THE LANCET.

*London, Saturday, November 13, 1830.*

In the long catalogue of "bad witnesses," medical men have been almost universally placed next in succession to barristers and attorneys, who *nem. con.* have been always inscribed at the very head of the list. The lawyers contend that they make such unhappy figures in the witness-box, chiefly from two causes,—their intimate and profound acquaintance with the multitudinous labyrinths of legal study, and the facility with which their actual defects are discovered and exposed by their brethren at the bar. So far as our experience has extended, *our* professional brethren have no such pleas to urge, and it still remains to be explained by lawyers, why that man who is supposed to be best acquainted with a subject, should communicate to his auditors the impression that he is least acquainted with it, when he is endeavouring to display his knowledge the most. The "bad witnesses," whom we have been in the habit of seeing in the ranks of our own profession, have had, we fear, but little claim to a profound acquaintance with the science in which they have dabbled. Ignorance, unmixed ignorance, either in themselves or in those by whom they were examined, has been generally the source of their failure. We say in their examiners, because medical testimony is often completely destitute of weight, and has not the slightest influence with the court, owing to the acquirements of barristers being entirely foreign to medical science. Therefore medical gentlemen cannot urge, as an excuse for their apparent imbecility in the witness-box, the tact, dexterity, research, and foresight of their scrutinizers. The study of medical jurisprudence has been completely neglected in the medical schools of this country, and there have been no medical judges, scarcely a

single medical coroner, to influence, even by the remote indirect demands of his office, the investigation of those matters which more particularly pertain to the proceedings of judicial inquiry. The cultivation of medical science has, however, of late years, proceeded with marked, satisfactory, and rapid steps of improvement, and in the man best acquainted with the principles and practice of his profession, we always find the most competent medical jurist. The medical witnesses, therefore, of 1830, are very different in attainments and influence from the medical witnesses of 1810; and, at the inquest on the unfortunate and *slaughtered*, we had almost said the *murdered*, Miss CASHIN, the evidence of the medical gentlemen left scarcely any-thing to be desired; it was at once perspicuous, scientific, and practical. It not only produced the proper impression upon the minds of the intelligent jury, who did not fail to feel its force, and appreciate its value, but it has given to our profession a peculiar stamp of authority throughout the whole country; hence it is now unhesitatingly admitted, that *competent* medical practitioners are fully equal to give *competent* testimony in a court of justice. There was, however, as we mentioned in our last number, an error which might have proved fatal to the cause of justice; and that its repetition was not thus disastrous on the late trial at the Old Bailey, must be attributed to the intelligence of the jury and the ignorance of ADOLPHUS.

Mr. BRODIE, who visited Miss CASHIN about ten hours previous to her death, stated at the inquest that he found Miss CASHIN's back "mortified;" and Mrs. RODDIS, in her luminous testimony, proved that the quack had directed mulled wine to be given to the young lady immediately before Mr. BRODIE's arrival. Of course it was a matter of great moment to *prove*, in such an inquiry, that LONG was grossly ignorant of the duties which he had voluntarily taken upon himself to execute. In order to produce a

conviction upon a charge of felony, it is not enough for the profession to *know* that LONG is ignorant, it is not enough for all the intelligent portion of the public to *assume* that LONG is ignorant; it was necessary that proof—direct proof, of his stupidity and rashness should be adduced at the trial, or the indictment could not have been sustained. Accordingly, at the inquest, we were anxious to obtain from LONG's own witnesses, what was his opinion (if the fellow be equal to connect two ideas upon a medical subject) of the cause of Miss CASHIN's death, and by constantly directing our attention to this point, we at last elicited from one of the witnesses, Mrs. General SHARPE, that LONG had told her that Miss CASHIN died from an "inflammation of the stomach." This was a fact of great importance, for here we had direct evidence of the wretch's brutal ignorance of even the rudiments of medical practice. What said Mrs. RODDIS? "LONG directed me to give the deceased a tumblerful of mulled wine." What said LONG to Mrs. General SHARPE? "The deceased had inflammation of the stomach." And what was the monstrous remedy? A TUMBLER OF MULLED WINE! Here was a point of great importance fully established; but in comes Mr. BRODIE, who, by one thoughtless movement, had nearly kicked down the whole fabric. At the time that Mr. BRODIE was examined at the inquest, he undoubtedly had some ground for believing that the skin was "mortified," for, upon looking at the part, a mere view must have led the most experienced eye to believe it was in that state, and Mr. BRODIE only saw it. At that time the part had not been cut into, and he merely judged of its condition from the greenish-black appearance. The body, however, subsequently underwent a most minute and careful *post-mortem* inspection; a portion of the skin was removed, it was shown to Mr. BRODIE, and the other medical witnesses all concurred in the opinion that

the skin was *not* mortified. In a word, with the exception of the dark film or pellicle which appeared to have been produced upon the surface of the cutis, the cuticle having been entirely abraded, the skin was not only *not* "mortified," but unusually vascular. The vessels were exceedingly enlarged, and the cutis, from this cause, was thickened to the extent in some places of the eighth of an inch. The mouths of the blood-vessels, when the cutis was cut into, were discernible at a considerable distance from the eye, so much had they become distended; but there was no coagulated blood, no line of separation, no yielding of texture; in fact, with the exception of the dark external appearance, there was not a single circumstance to justify any man in asserting that the state of the part even *indicated* the approach of mortification. Then how inaccurate, and therefore unfortunate, was the evidence of Mr. BRODIE. Besides, there is an unaccountable disagreement between the opinion which that gentleman says he entertained of the condition of the wound, and the treatment which he adopted. Here is an exact copy of Mr. BRODIE's prescription:—

"R Potass. carbon., ʒij;  
Spir. myrist., ʒij;  
Aq. menth. sativ., ʒiiss;  
Tr. opii, ℥ x.

"M. ft. mist. cujus capt. sextampartem  
sextis horis cum coch. ampl. succi  
limonis in effervescent.

"B. C. Brodie.

"For Miss Cath. Cashin."

How squares such a prescription with "mortification" produced by violent, and still existing, inflammatory action? Beyond all question, Mr. BRODIE must confess that he was strangely in error, either in his therapeutics or in his pathology, and we feel little hesitation in asserting that he was wrong in both. Mr. BRODIE saw the wound, and was furnished with ocular proof that it was in an active state of suppuration, discharging, indeed, not less than from a pint to a pint and a half of pus daily; yet he

swears on two occasions that this highly vitalised, highly organised part was "mortified," and for the patient labouring under the violent, the almost unparalleled inflammation by which the supposed "mortification" was produced, he prescribed six scruples of the carbonate of potash, ten drops of the tincture of opium, three ounces and a half of mint water, and three drachms of the spirit of nutmeg with lemon juice, to be taken in the *short* space of *thirty-six hours*! One scruple of the carbonate of potash, and one drop and two-thirds of laudanum, every six hours! This surely was not the best and only treatment which a man of Mr. BRODIE's experience and attainments could adopt, in the occurrence of "mortification" caused by excessive inflammation. If the first dose of the medicine had been rejected, then the poor girl must have remained until six hours had elapsed before she could derive the ease and consolation capable of being afforded by one drop and two-thirds of laudanum! In a word, if Mr. BRODIE were correct in his diagnosis, his treatment was miserably incorrect and inefficient; but, having been completely wrong in his diagnosis, his error had nearly caused the escape of the felon LONG.

Mr. BRODIE, we believe, is a very honourable gentleman, and would not for a moment make a statement which he deemed to be untrue; but, as the error into which he has fallen might have proved doubly fatal, we trust that on all other occasions he will adopt the necessary means for arriving at a correct knowledge of disease, and thus protect his patients against a repetition of such inefficient treatment for "mortification," and the public against the chance of such abandoned fellows as LONG escaping from punishment.

Come we now to the trial at the Old Bailey, and taken as a whole it was probably one of the most disgraceful scenes ever witnessed in a court of justice, the sentence

having been the climax. On the trial of COOPER v. WALKER, several of the plaintiff's "eminent" witnesses, it will be recollected, sat upon the bench, and at no great distance from the judge; but Lord TENTERDEN, in passing over this unwarrantable and offensive presumption, differed from his brother of the Old Bailey, in not allowing the witnesses to converse with him both before and after they had given their evidence. It is literally a fact that during the trial the Marchioness of ORMOND was snugly seated by the side of Mr. Justice PARK, spoke to the judge in the progress of the trial, and repeatedly nodded assent (as well she might, being LONG's witness), while the learned judge was delivering his charge to the jury. Why, we ask, was the Marchioness of ORMOND on the bench? Why was there any attempt made to influence the minds of the jury by such a display of rank and power on the bench, in favour of the prisoner? If the Marchioness of ORMOND could associate with a felon, could still show such partiality for a man who had inhumanly destroyed an unoffending, innocent fellow-creature for the sake of paltry gain, surely her ladyship, without any dread of contamination, without any fear of deteriorating her refined taste, or insulting her "order," might have taken her stand in that situation which is properly assigned for all individuals who attend for the purpose of giving evidence, namely, the witness-box. Judge PARK was quite pathetic, quite lachrymose, when declaring that there was no distinction made between rich and poor in that court; but would the learned and discreet judge have taken by his side the wife of a poor tradesman who had come to speak to the character of a pickpocket? No; nor the wife of a rich tradesman: it was the *title* that gave the *entrée* to the seat of—we must say justice, we suppose. The aristocracy appear to be racing against time, in their endeavours to bring themselves into disrepute with all the thinking part of the com-

munity. Incapable of commanding respect, or of attracting attention by actions of an exalted character, they seem to labour unceasingly in their exertions to attract notice by the excesses of folly and pride. John LONG is worthy of his supporters, and the "order" quite befitting the felonious quack whom they have apparently solemnly sworn to patronise.

The Editors of the various public Journals have commented on the proceedings in this trial in terms of well-merited opprobrium. A whole torrent of sarcasm and ridicule has been poured down upon the heads of the "order;" but, like "the Tenth," the "order" can't feel ridicule; no matter how biting, how pinching, how withering, the "order" are quite proof against annoyance, and equally protected against improvement. If they had not been the veriest dolts that breathe, they must long ago have perceived that LONG was an unprincipled impostor,—a juggler, a knave. But the felon endeavoured to convert his house into a lounging stool for the silly things, and it became "fashionable" to support Mr. Singe—ing LONG; it became fashionable to "inhele" through long red morocco tubes, to undress, to expose the person before this painter and limner, and to be "rubbed" with his brush. These things became fashionable, and so beneficial withal, that titled dames and nursery misses could go forward in the presence of hundreds of spectators, and attest the "skill, humanity, and kind attention" of the artist! Monstrous exhibition! But the juries were not to be blinded by all the aristocratic dust that was thrown into their eyes; nay, nor were they to be frightened or diverted from the honest discharge of their duty by the rigmarole tale of the coroner, or the specious summing up of the judge. They have merited and received the thanks of their countrymen for their impartial and intelligent verdicts; the press has every where approved of their conduct. On the Mon-

day after the trial, the *Times* said, that it "sincerely rejoiced in the verdict;" but sentence had not then been pronounced. The *Times* rejoiced, probably, in the verdict, because it perceived in the declaration of the judge, "that there was no distinction to be made between the rich and poor; that justice must be dealt to the one as well as to the other;" that a sentence would be pronounced which must have the effect, at least for a time, of protecting the public against the atrocious frauds and "killings" of the felon. There may be some excuse for any thing said by Mr. Justice PARK on the Saturday night, as he appeared to sit awfully aghast when the verdict was pronounced. He was quite astounded; so much so, that he knew not what sentence to pronounce; he required time, "until Monday; but that could make no difference, as the punishment would be probably imprisonment." To be sure, then, as there was to be no distinction between rich and poor, it could make little difference whether the sentence were pronounced on the Saturday night or on Monday. But when Monday arrived, what was the sentence passed upon the author of a most atrocious felony? what was the sentence passed upon a man who had been convicted of a most infamous manslaughter? what the sentence pronounced upon a felon, whose "goods and chattels" had been forfeited to the King by the verdict of the jury?—this poor man, who had lost his all, who had not a shilling in the world, nor a friend to help him to one? Why a FINE of two hundred and fifty pounds, and to be imprisoned until such fine were paid. There—that's the way to maintain an even line between rich and poor. Mr. Justice PARK of course would have passed the same sentence upon a labouring man, towards whom it would have amounted to one of perpetual imprisonment; for how would the labouring man have obtained the two-hundred-and-fifty pounds, seeing too that the few shillings

he had possessed before the trial had been forfeited to the crown by the verdict of the jury? The judge, therefore, thought not of Long's rich aristocratic connexions; thought not of any assignment that he might have made of his property before the trial; thought not of any funds that he might have gained by his jugglery, and secreted from the King's officer, the sheriff. No; the learned judge resolved that the stream of justice should not be polluted by his hands, that there should be "no distinction between rich and poor," that he would sentence LONG to a fine of two hundred and fifty pounds, because, like other poor men, who had committed similar acts of atrocity, he should be imprisoned for life, that the public might be guarded against a repetition of his nefarious and destructive practices. The humane judge, however, unhappily was not a match for the cunning of the criminal, who, it appears, had cheated the sheriff, and had not only sufficient money in his pocket to discharge the fine, but plenty to spare. Within five minutes, this poor man terminated his "perpetual imprisonment," and was riding cheek-by-jowl with Lord SLIGO, in his Lordship's curricule. Who can withhold his commendation from the judge, for the manifestation he has thus made of his severe attachment to even-handed justice!

The whole of our contemporaries, in noticing this trial, appear to have forgotten that a "felon's" property is forfeited to the crown, therefore if only two hundred and fifty pounds have been taken from LONG, the KING has been made to subscribe handsomely to the FELON for his kind and considerate "slaughter" of the unfortunate Miss Catherine CASHIN! Is this the law! is this the justice of England!

---

THE PROSECUTOR'S COSTS IN THE TRIAL OF  
JOHN LONG.

"Dr. Johnson thinks the profession ought to indemnify Mr. Wakley for the expenses

of St. John Long's trial, and offers his mite of five pounds for that purpose.

"Suffolk Place, Pall Mall East,  
6th November, 1830."

In acknowledging the receipt of this note, which, from a variety of circumstances, cannot be otherwise than gratifying to our feelings, we beg to state that Mr. Henson, the solicitor, has given us to understand that upon presenting a petition, supported by affidavit, to the Lords of the Treasury, the prosecutor's costs will be allowed out of the fine paid by the FELON. This is the source whence *every* expense incurred by the prosecution ought certainly to be defrayed.

#### THE FELON AGAIN!

A LADY, of the name of Lloyd, has now fallen a victim to the "*rubbing*" system of this atrocious quack. The unhappy sufferer expired, in the most excruciating tortures, about ten days after she had first been "*rubbed*." A horrid wound was produced on the breast; and, according to the evidence of the medical witnesses, the consequent inflammation and mortification were of great extent. A coroner's inquest sat on the body on Wednesday, which was adjourned to Thursday; and just as this sheet of our Journal was going to press, we heard that the jury had returned a verdict of "*manslaughter*" against LONG. A few persons have had the temerity to assert that the late sentence was a scandalous one; what will they say now?

Dr. ELLIOTSON thus concluded his clinical lecture, delivered on Monday last at St. Thomas's Hospital, on the impositions sometimes practised by patients on their medical attendants.

"Remember, gentlemen, that though patients sometimes deceive medical men, practitioners often deceive their patients. It is but fair, then, for patients to play these tricks upon us; especially if we take into consideration that any one may practise upon their credulity with impunity—that quackery may flourish; that the most ignorant may practise in spite of the Royal College of Physicians, and the Royal College

of Surgeons, and the Worshipful Company of Apothecaries; that no one can touch such persons; no one can prevent their proceedings; for, of course, those great bodies would do their duty to the public if they had the power to interfere. A quack may make his twelve thousand a year in spite of any laws that can be put in force against him; and if he do chance to destroy a few of his patients, we know that he can be allowed to do so at the rate of two hundred and fifty pounds a head. We can afford, then, to forgive our patients for occasionally deceiving us in return."\*

#### ST. BARTHOLOMEW'S HOSPITAL.

##### EXTENSIVE FRACTURE OF THE PELVIS.

JOHN SMITH, *etat.* 27, was admitted into Colston's Ward, on the evening of the 13th of October, under the care of Mr. Vincent. He complained of his left hip being injured, and on examination, a point of bone was discovered, projecting a little above the centre of the dorsum ilii of that side. No solution of continuity could be detected in the extent of the crista, and the severed fragment was supposed to be a portion of the external table of the ilium. The swelling of the soft parts, which had taken place previous to his admission, entirely precluded the possibility of ascertaining the precise direction and extent of the fracture. Some difference of opinion, we understand, arose as to whether a second fracture of the posterior portion of the ilium existed, or a dislocation at the sacro-iliac symphysis. He complained of excessive pain in the injured part, which was exceedingly increased on the slightest motion of the thigh. Mr. Vincent was sent for, and arrived in about half an hour. He examined the parts with great attention, and thought that the fracture of the ilium extended in the direction of the acetabulum, and that the horizontal ramus of the pubis was also fractured. Soon after his admission, there was an involuntary discharge of feces, but there was no paralysis of the bladder or lower extremities.

He stated that he was a wagoner, and was in perfect health previous to the accident. He was driving a wagon over Blackfriars Bridge, and slipped from off the curb-stone on the carriage-road, and fell with his left hip against the ground. He stated distinctly, that the wagon did not pass over him, nor touch him in the slightest degree, and he attributed the injury he has sustained solely to the fall.

\* We had not room for this lecture in our present Number.

Mr. Vincent ordered him to be laid on his back, and to have ʒij of blood taken from the hip by cupping, and afterwards a broad bandage to be put around the pelvis.

Oct. 14. Has passed a sleepless night, in consequence of the severity of the pain in the injured parts. The rectum is now under the influence of the will. The bowels have not been open since last night. He lies with his thighs widely separated, and says he is easier in that position than in any other. He is still in a great deal of pain. An ounce of castor oil to be taken immediately.

15, ten A.M. He complains of acute pain about the angles of the 7th, 8th, and 9th ribs of the left side; his respiration is frequent, painful, and hurried. The ribs appear to be immoveable, particularly those corresponding to the seat of the pain. His tongue is white, skin hot and dry; pulse 100, strong and full; a deep inspiration produced cough and increased the pain. The pain in the hip is still severe; bowels freely relieved yesterday by the castor oil. To be bled to 18 ounces immediately.

Six P.M. The pain and breathing were both relieved by the V.S.; his pulse rose to 110, and became soft; within the last three hours he is become considerably worse, and the pain in the side is more severe than it was in the morning. The blood taken at ten o'clock is very much buffed and cupped. Bleeding to be repeated to 18 ounces immediately; to have a saline draught, with the solution tartar emetic every fourth hour.

16, eleven A.M. Felt relieved by the bleeding, but is now worse than before he was bled. Blood drawn last night buffed and cupped; cough very much worse, and kept him awake all night; he expectorates a great deal of viscid mucus. He now experiences severe pain in the abdomen at each inspiration. Eighteen leeches to the chest, and the same number to the abdomen. The abdomen to be well fomented after the leeches are taken off. Venesection to 18 ounces immediately.

Ten P.M. Much worse in every respect.

17, two A.M. The bleeding produced the same effect as on previous occasions. He has now more difficulty of breathing, and the cough is attended with a more copious expectoration. The pain in the side has extended over a larger surface, and is much increased in intensity. There has been no occasion for aperient medicine since the 14th inst. To be bled to 18 ounces. Continue the saline antimonial mixture.

Eleven P.M. Was relieved by the bleeding, and slept for three hours after it. His respiration is now very laborious; the blood continues buffed and cupped; pulse has continued at about 120, and very full, since

the 15th, and still remains so. Venesection to 18 ounces.

18, two P.M. He is daily getting much worse; his expectoration is now attended with great difficulty, and the respiration is exceedingly laborious. He complains of pain in the fore part of the thigh, which was bruised at the time the accident occurred. The pain in the abdomen has not been severe since the 16th, and he can now bear pressure on it pretty well. He complains of severe pain over the trochanter major. Let him be bled from the arm to 20 ounces; cupping on the hip to 18 ounces. Discontinue the saline and antimony, and take of solution of acetate of ammonia ʒjss.; ipecac. wine, 16 drops every fourth hour.

10 P.M. Still great difficulty of breathing; and the pain in the chest rather increased; pulse very rapid, but much softer and very small; in other respects the same. Add ten drops of tincture of digitalis to each of the above draughts.

19, Two P.M. Feels considerable pain in the abdomen to-day; has passed a very restless night; pulse still very frequent, but much fuller than last night; he now complains of great debility; in other respects the same. Twenty leeches to the chest; twenty leeches to the abdomen, with fomentations.

Nine P.M. Worse than in the morning; pulse rather stronger and fuller; venesection to twelve ounces.

20. All the symptoms are increasing rapidly; he is sinking fast; bowels still continue open.

21. Last night he became delirious, and still remains so; his eyelids are half-closed; breathing rather easier, and the pain in the side is also easier; pulse still full and frequent; countenance exsanguine and of a citron tint.

22. Died last night at eleven o'clock,

#### *Examination 14 hours after Death.*

*Brain* healthy.

*Chest*.—The pleura covering the posterior surface of the left lung, and that lining the corresponding part of the wall of the thorax, was covered with a thick layer of yellow, opaque, and very tenacious lymph. On removing this lymph, the pleura was found minutely injected, and dark-red spots were visible beneath it. The lung throughout was less crepitant than natural, and when cut into, pus exuded from the ramifications of the bronchial tubes. The entire lung was in a state of *engouement*. There was no change of structure. The right lung was tolerably healthy.

*Abdomen*.—Peritoneum slightly inflamed; pus was found in the *poas magnus* of the left side in its whole extent. The abdominal and pelvic viscera were healthy.

*Pelvis.*—The soft parts over the ilium were in a state approaching to gangrene; there was a comminuted fracture of the left ilium, which commenced about two inches and a half from its anterior superior spine, extended through the substance of the bone in an oblique direction, and having described a semicircle, terminated at the sacro-iliac symphysis. The remaining portion of the ilium was separated from its articulation with the sacrum, and thrown considerably upwards and forwards. The ramus of the left ischium, and the horizontal ramus of the corresponding pubes, were also fractured. A small collection of pus was found within the capsule of the hip-joint, and the cartilage of the acetabulum was in several parts absorbed.

## SINGULAR EFFECT OF LIGHTNING.

WE lately communicated a very remarkable instance of the effect of lightning on a man who, though the shock seemed to have passed directly through him, afterwards completely recovered; we find a similar case in a late number of the "Kuitische Repertorium." On the 5th of last May, in the neighbourhood of Moersbach, a large oak was struck by lightning, at the time when two children were standing underneath. They were found a short time after the accident in a state of complete insensibility, from which, however, they soon recovered. The elder, eleven years of age, had on the outer side of the left thigh, a livid streak, about half an inch in breadth, and five inches in length; another two inches in length, on the posterior surface of the left upper arm; and a third from the inner angle of the right foot to the great toe, where the shoe was completely torn through. The other child, seven years of age, had only one streak at the outer side of the left thigh, terminating at the knee; both children complained of great lassitude, stiffness of the limbs, and pain in the abdomen; but after the use of aperients and the external application of camphorated spirit, completely recovered in ten days.

## ERRATUM.

*To the Editor of THE LANCET.*

SIR,—I perceive in "THE LANCET" of the 6th November, an anonymous communication, containing strictures on the professional character of Sir W. Blizard, and dated the 12th of October, 23, Hadlow Street, Burton Crescent.

As that has been my place of residence since the 29th of September, and as I have communicated to THE LANCET an authenti-

cated article (besides two advertisements of Lectures) with that address, I beg you will afford me the earliest opportunity of emphatically disclaiming the slightest connexion with the anonymous communication.

I am, Sir,

Your obedient servant,

W. B. O'SHAUGHNESSY, M.D.  
23, Hadlow Street, Burton Crescent,  
9th November, 1830.

## SURGICAL PRACTICE IN WORKHOUSES.

*To the Editor of THE LANCET.*

SIR,—Under the impression from the past, that you are always ready to expose in your valuable periodical, all professional "humbug" and "hole-and-corner practice," I am led to ask insertion for these lines, arising from a sincere wish that, as medical students pay the most exorbitant and shameful fees for the little knowledge they are enabled to acquire, so they should in like manner, make the most of it whenever an opportunity presents itself. I am an apprentice to the surgeon of one of our largest metropolitan workhouses, and in latter part of my time, from which, up to the period when I entered the profession, I have invariably been allowed to examine and derive what knowledge I could from the cases contained in the ward appropriated to the male venereal patients; but, will it be believed, in the present enlightened state of the profession, when I write that the surgeon of the establishment refuses to admit me when he examines female cases, differing frequently from the disease in the male, in consequence of the difference of the parts, and, forsooth, because his sense of decorum bids him pronounce his "veto." "O chastitas! O pristina fides!" Surely nothing can exceed the well-timed benevolence of this worthy man, in thus sparing the feelings of generally the lowest class of prostitutes, and, in consequence, denying a stripling of twenty-one, who has paid him handsomely, to acquire all professional knowledge, and who possesses an anxious wish to understand his calling, from witnessing cases which tend to illustrate and afford to the student correct pathological data relative to this important disease.

In begging you a sincere pardon for thus trespassing on your press and patience,

I am, Sir,

Your most obedient servant,

A CONSTANT READER.

Oct. 28th, 1830.

\* \* If the writer of this letter be of mature age, we think the restriction imposed by his master is neither sensible nor just.

## TO CORRESPONDENTS.

COMMUNICATIONS have been received from Mr. Morson—An Enemy to Humbug—Vindex—Mr. H. D. C. De La Motte—Mr. John Barrow—Mr. Williams—Martin Evans, M.D.

Dr. Blicke's communication shall appear next week.

S. P. Yes; but it must be done with caution.

*Chirurgicus.* We are firmly of opinion that a member of the College of Surgeons can dispense his own prescriptions without hazarding the penalties of the Apothecaries Act. The chemist and druggist certainly incurs no risk at all.

*A Junior Member of the Profession.* Out of the house from 60 to 80*l.* per annum, but such situations are very rare; as indoor assistant, from 2*l.* to 4*l.*

*Alpha.* That state originates from such a variety of causes that it is impossible to give a satisfactory reply to his question in this case.

If M. D. of Edinburgh will send his name and address to our office, his request shall be attended to.

*Scalpellum,* on reflection, must be aware, that to insert, unauthenticated, such letters as the one he last sent, might be an act of very gross injustice to Sir——, and if the principle were widely acted upon, would bring a scandal upon the press generally, and completely neutralize its good effects.

The unfair dealing of which a writer signing himself *Salus Populi* complains, sinks into nothing when placed in comparison with the disgusting knavery and jobbing which are daily practised in most of our dispensaries and infirmaries. His letter is too general to produce a good effect. The title of the institution, and the names and addresses of the underhand members of the committee should all be published.

H. M. Such a party cannot recover in a court of law for medicines and attendance. He certainly is liable to no penalty for the mere act of sending in an account.

A correspondent says he cures the tooth-ach by putting "two or three drops of prussic acid on a bit of lint and inserting it in the cavity of the decayed tooth!" He cannot be serious.

The communication of *Humanitas*, or some remarks on it, would have been inserted, had not the letter been accidentally mislaid.

*An Inquirer.* It is contended by the lawyers, that the Apothecaries Act has altered the law. We contend for the contrary. The question has not yet been fairly tried.

*Bibliophilus.* The second volume of Dr. Mackintosh's Practice of Physic was published a week or two ago. It is an excellent work.

The plates in question we have not seen, but original drawings from the same hand, which we have seen, were neither well drawn nor well coloured.

The Atlas is an able production. A. T. T.'s edition of Bateman is the most proper companion to it.

The works of Beck and Christison.

*A Webb Street Pupil.* We are too much pressed for space to insert the questions propounded by the Examiners of the Company of Apothecaries. Nevertheless we feel obliged to our correspondent for his communication.

*A Pupil* is greatly mistaken in supposing that any such change in our "medical politics" has taken place. The expressions to which he refers were the sentiments of a correspondent. It certainly never was the intention of the legislature to grant the powers which have been assumed, and a radical change in the government of the body is probably at hand. The principle, however, for which our correspondent would argue, he must, on reflection, agree with us, is not a sound one, for surely the qualifications of the individuals to whose care the health of the community is mainly committed should be carefully examined.

*A Non-Medical Subscriber* will find the subject at page 82 of Cooper's Surgical Dictionary.

We may refer H. F. to page 144 of our last LANCET.

## BOOKS RECEIVED.

Elements of Pathology and Practice of Physic. By John Mackintosh, M.D., Lecturer on the Practice of Physic in Edinburgh. Vol. II. Edinburgh: Carfrae. London: Longman. 8vo. pp. 467. 1830.

The Pyramid, Prospectus of a General Cemetery, to be erected in the vicinity of Primrose Hill. Thomas Willson, Architect. London, 1830.

An Introductory Lecture to a Course of Anatomical Lectures. By Thomas Firth, Surgeon. London: Limebeer. 1830. pp. 32.

## ERRATUM.

At the close of the report of the London Medical Society in our last, page 220, the last line should have been printed "and certainly it would be rather too much to tell him that he had never met with a case of puerperal fever."

# THE LANCET.

Vol. I.]

LONDON, SATURDAY, NOVEMBER 20.

[1830-31.]

## *Hôtel-Dieu de Paris en Juillet et Août 1830. Par PR. MENIÈRE.*

INDEPENDENTLY of the great political interest which is attached to the history of the Hôtel-Dieu during the months of July and August, this hospital being almost in the centre of the field of battle, the above report is important in a medical point of view, and we think we shall obtain the thanks of our readers for presenting them with some extracts.

On the evening of the 26th of July, the day of the publication of the ordinances, the number of patients in the Hôtel-Dieu amounted to 878; on the morning of the following day some disturbances took place, and in the evening the fighting began between the citizens and gend'armes. On that night six wounded persons were conveyed to the Hôtel-Dieu, and one of them died almost immediately.

At the very beginning of the struggle, the medical authorities of the Hôtel-Dieu considered it necessary to discontinue the further admission of patients, except in urgent cases, and to discharge as many reconvalescents as possible, so confident were they that a serious conflict was at hand; and owing to these wise measures, the hospital contained on the evening of the 27th, only 900 patients,\* a great number of whom were in a state to leave on the first notice.

During the disastrous fight on the 28th, 110 wounded citizens were admitted, 17 of whom died on the same day; the wounds were all from musket balls, cartridges, and cannon balls. Every-thing was immediately done to assist the wounded, and to provide for the morrow. Thirty-eight convalescents left the hospital, some of them to

take part in the fight. An additional number of beds was placed in the different wards, and a "service d'ambulance" was organised; a large number of old "internes" of the Hôtel-Dieu came to the hospital, and offered to place themselves under the "chirurgien en chef," and to share the service of their younger colleagues. A large number of litters was distributed over the immediate neighbourhood of the hospital, in order to carry the wounded from the conveyance in which they had been brought, into the wards—a measure which was indispensable, as every wounded man being accompanied by a large escort of friends, they would have otherwise entered with him, and have caused great confusion in the wards. As it was necessary to perform many operations immediately, one particular ward was destined for that purpose; this plan was, however, soon found to be impracticable, as the number of wounded rapidly increased, and the operations were accordingly performed on the beds of the patients themselves. M. Dupuytren performed nearly all the operations himself, not only the greater operations, but also such as enlarging of the wounds, extraction of balls, &c. A great number of wounded left the hospital after their wounds had been dressed, some to go home, but others to return to the fight; and M. Menière states, that he saw more than one who was wounded, at two, three, and even four, different periods of the battle. From this day wounded soldiers were also admitted; they were placed in the same wards with the wounded citizens, as there was no time to assign to them a particular ward; besides, it was soon found that there existed no sort of animosity on the part of the citizens against them, and within a few days they were completely fraternized.

After the murderous night of the 28th, a

\* The average number of daily admissions at the Hôtel-Dieu, is about 38.

sort of armistice was concluded, which the troops employed in throwing their dead into the Seine, and in carrying their wounded to the "ambulances," and the "Hôpital de la Garde;" a great number of the most severely wounded was also brought to the Hôtel-Dieu. It was on this occasion particularly that the citizens, animated by the most generous feelings of humanity, made themselves worthy of the greatest praise; they themselves carried the wounded soldiers to the hospitals, and evinced the same care and attention to them, as if they had fought for their own good cause.

After a short cessation of hostilities, the battle recommenced, and terminated on the evening of the 29th; on that day no less than 204 wounded persons were received at the Hôtel-Dieu, twenty of whom died before any surgical treatment could be administered to them. All the other patients of the hospital who were in a state which admitted of their being conveyed, were discharged, and 362 of them were sent to the Salpêtrière and the Bicêtre, in order to make room for the wounded, the number of whom was expected to increase after the battle. Several young surgeons were stationed at a greater distance from the hospital (the neighbourhood of which became by this time really covered by litters, &c.), in order to assist such as required immediate aid, as in case of hæmorrhage, &c.; others were sent into other quarters of the town, for the purpose of establishing ambulances for the temporary reception of the wounded, until they could be sent to the hospitals. Those of the wounded who could bear being conveyed were carried to other hospitals; others were removed to their homes, or into houses in the neighbourhood.

About 400 wounded persons received this sort of temporary surgical treatment at the Hôtel-Dieu, and it is necessary to remark that these are not comprised in the general report of the hospital.

During the following four days fifty-eight wounded were admitted, and their admission continued for some weeks, but of course most of the wounds were less dangerous. The greater part of these were workmen, who found themselves unable to provide for the expenses of a long illness. During the same period, a great number of those who had received temporary treat-

ment also returned to the Hôtel-Dieu, where they were further attended as out-patients.

The total number of wounded, who were regularly admitted into the hospital, amounts to 390, of whom 302 were citizens, 62 soldiers of different ranks, 21 females, and five children under fifteen years of age. Forty wounded died during the first three days after their admission.

We shall now say a few words on the internal organisation of the hospital, and the distribution of medical service, during and immediately after the revolution. Besides the five surgical wards, three medical wards which had been evacuated in the manner above described were destined to receive the wounded; the surgical service was organised by M. Dupuytren, under whom all the surgical officers, not only of the hospital, but also the old "internes," and other surgeons, who had volunteered their assistance, placed themselves; the "chirurgien en chef" immediately assigned to every one his post and appointment, and it was owing to the strict adherence to these orders that the service of the hospital was, during the whole period, performed without the least confusion or interruption; the morning visit, which generally took about five hours, was made by M. Dupuytren, and the evening visit alternately by his colleagues, MM. Breschet and Sanson. As to the frequent complaint of the Hôtel-Dieu having been crowded, it is sufficient to say that in consequence of the discharge of convalescents and transportable patients on the evening of the 28th, the number of patients amounted only to 771, a number considerably less than can be accommodated at the Hôtel-Dieu; during the following days also, the number of discharges always exceeded that of admissions; and the number of patients in the hospital was, on an average, not more than between 680 and 710; a statement for the authenticity of which M. Menière declares himself responsible.

The diet at the hospital is rather indifferent, and M. Dupuytren justly considered the present a very proper opportunity of making improvements in this respect; orders were immediately given to the domestic department of the house to make the proper alterations; and it is probable that to these measures, and to the liberal contributions

of the citizens themselves, the speedy recovery of many patients may be ascribed.

Another want which soon became very urgent, was that of lint and linen, but this had no sooner begun to be known in the town, than large donations were sent from all quarters, particularly from the "Dames de la Halle," the "Collège Louis-le-Grand," the hospices, and even from other towns as far distant as Angers; at the same time a great number of workshops was established in the neighbourhood of, and on the very place before, the Hôtel-Dieu, to supply the wards with lint, bandages, &c. By such efforts, and lastly from the contents of the magazine of the "ambulances de l'armée," which was immediately given up by the provisory administration to the civil hospital, these wants were speedily supplied. Another circumstance which was extremely beneficial in this respect deserves notice: the palace of the archbishop (which is quite close to the hospital) having been invaded, a report spread that it was to be plundered, and the furniture destroyed and thrown into the Seine. In consequence of this rumour, M. Breschet immediately proceeded thither with his apron (in his dress as hospital surgeon), and called upon the people in the possession of the palace to carry everything that might be useful to the wounded, to the Hôtel; these orders were immediately followed, and all the linen, beds, furniture, and even money, was faithfully delivered to the authorities at the hospital. Another incident connected with the archbishop's palace must here be mentioned. Some of the people were going to set fire to the building, and others proposed to dig a large hole in the garden, and to bury there a great number of dead from the Place de Grève, &c.; but as soon as they were reminded that the execution of either of these plans might be injurious to the Hôtel-Dieu, they immediately abandoned them. In conclusion of this part of his report, M. Menière mentions the honourable readiness with which the medical officers of the hospital adopted the proposition of one of their colleagues to make a collection for the wounded, which, within a few days, amounted to about six thousand francs (240*l.*).

We do not follow M. Menière in his inquiry on the nature of gun-shot wounds, as this is for the present foreign to our pur-

pose. We also omit entering into many particulars respecting the severity of the cases, such as for instance that the citizens were more dangerously wounded than the soldiers, but that in the former the wounds were comparatively less fatal than in the latter, because of the different emotions of mind which were necessarily produced by the event of the struggle, &c.

We give a short extract of some of the most interesting cases:—

"A soldier of the Royal Guards received a shot a little above the temporal extremity of the eyebrow; the ball having traversed the skin and temporal muscle, glided along the skull in a semicircular direction till it came behind the ear, where it stopped; it was extracted by means of an incision. The patient went on very well, till all at once hæmorrhage took place from the temporal artery, which was, however, soon arrested by the ligature; this patient is now recovered.—A pupil of the Polytechnic School was stabbed in the right eye; the instrument pierced the orbit and perforated the brain in its whole length, and of course produced immediate death.—A deaf and dumb person, about 34 years of age, who had taken a very active part in the fighting, was brought to the hospital covered with wounds, and lacerated in the most pitiful manner; there was a penetrating wound at the temporal region of the skull, and there was evidently a lesion of the brain; he was largely bled and went on favourably, when secondary encephalitis acceded and carried him off in a few days.—A citizen received a ball on the forehead; he was brought to the hospital in a state of insensibility; the skin was found lacerated, but there was no fracture; when he recovered his senses he was quite blind, and it was only after a few days that the right eye became sensible of light; the vision of both eyes was gradually but completely restored.—One fracture only of the clavicle was observed, from a blow with a musket, and curiously enough it was in a citizen who had recently been discharged from the Hôtel-Dieu, after recovery from a fracture of the clavicle of the other side.—Two exarticulations of the upper arm were made with success; a third case proved fatal, probably only because the patient objected to the operation being performed immediately after the accident.—A few severe cases of burns were also admitted. Some citizens had taken possession of a cannon, which they directed against the enemy, but in the heat of the moment they had put the ball behind the powder; the cannon was accordingly turned, and the powder was scattered over the pavement; the ball also fell on the stones, and unfor-

tunately caused a spark, by which the powder took fire and burnt five or six individuals.—A young man, with his pocket filled with cartridges, had a pistol discharged close to him, so that they took fire, and he was in one moment burnt from head to foot. None of these burns were fatal.—One case of amputation of the index of the left hand proved fatal, in consequence of nervous symptoms supervening, which were probably caused by a violent emotion of mind.—In two cases both thighs had been traversed by the same ball without producing fracture, and in one the ball had even perforated both legs without even any lesion of the bone.—One case of tetanus only was observed, in a patient with penetrating wound of the chest; it seems that it was principally caused by the frequent discharges of muskets and pistols, which continued for a considerable time after the fighting had ceased. Several cases were observed, in which the ball had passed through the neck without injuring any important organs, and some of them were speedily cured; some, however, proved fatal by hæmorrhage, as was the case in a young man who had been shot through the neck, and was in a fair way of recovering, when, on the 12th day, hæmorrhage occurred and carried him off within a few hours.—A boy of 17 received a large wound at the left side, immediately above the heart; the ball, after having broken a rib, traversed the lung and the scapula, and he was apparently in a dying state when he was admitted at the hospital; reaction, however, soon took place, and it is hoped that he will recover.—A voltigeur received a musket-ball on the occiput; though it came in an oblique direction, it fractured and depressed the skull, and such was its force, that it was almost divided into two parts, one half having entered the cerebellum and the other remaining outside; it was very firm, and it required a great effort to detach it; the patient died on the second day.—A young girl, whilst looking out of a window on the fifth story, received a ball in the breast, after it had penetrated the chest of a man before her; happily she was thickly clothed, else the ball would have entered the chest; it had been fired at the distance of about 60 paces.—A soldier of the Guard was shot in the hypogastric region; the neck of the bladder was wounded, and the ball entered a little above the anus; the os pubis was fractured. Notwithstanding the extent and the nature of the wound the patient lived till the 30th day, when he died of inflammation.”

With respect to the situation and effects of the wounds, there were observed to be,—

		FATAL.
Wounds of the head *	20.....	13

	274	99

Besides the above number, eleven citizens died almost immediately after admission, and their wounds were not specified. The total number of deaths is stated to have been 122 (which however does not accord with the above), 40 of whom, at least, did not admit of any surgical treatment. Of the 91 wounds of the extremities without fractures none proved fatal, and it was peculiarly fortunate that there were no penetrating wounds of the joints among them. The other wounds, which are not entered in the above list, were comparatively slight. At the end of September there were but twenty wounded left; the greater number of convalescents having been sent to St. Cloud, where the barracks of the Gardes du Corps had been appropriated to that purpose.

---

*Transactions of the Medical and Physical Society of Calcutta.* Volume the fourth. Calcutta: Thacker and Co. 1829. 8vo.

OF the thirty-three articles contained in the volume before us, a small number only require our notice, the rest being chiefly on subjects of local importance, and such as can afford but little interest to European readers.

We shall begin with the first paper, on lactucarium, by Dr. Graham, who caused a quantity of this drug to be prepared, and employed it in a number of cases with con-

---

\* At the Hôpital Beaujon, a citizen was admitted with eight wounds of the head, at one of which a piece of bone three inches long and two broad, had been separated from the skull; he recovered, and is at present in St. Cloud.

siderable benefit. It was obtained from the coss lettuce just before flowering, by cutting the stem obliquely into a great number of pieces, and scraping off the juice from the ends of each with a broad blunt knife, by which it was conveyed into a cup or bason having a cross-bar and containing a small quantity of water. The juice thus collected was merely inspissated by standing for a short time in the shade, and then made into cakes with the hand, without being subjected to any other preparation whatever. It was given in somewhat larger doses than those which have been hitherto recommended, viz., from two to eight or ten grains, and was productive of very beneficial effects in several instances where opium and other narcotics had failed, or could not be borne by the patient. In this country the expense attending the collection of lactucarium has been so great as alone to prevent its being brought into general use; but Dr. Graham states that the above method of preparing it is already understood, in several places, by the natives, and that any quantity of it might easily be procured at a very reasonable price. In the appendix an account is given of some trials which were made with a quantity of the drug sent by Dr. Graham to Calcutta, and the results fully justify the commendations which he bestows upon it.

The seventh article contains a very interesting case of diabetes completely and permanently cured by bleeding. The patient, a military officer *æt.* 40, had been ill several months, and was extremely weakened and emaciated, when he applied to Dr. Kennedy. His previous medical attendants had considered his case as one of hypochondriasis and general debility, without being at all aware of its real nature, although he was actually at this time voiding from ten to twelve pints of inodorous sweet urine in the twenty-four hours. Leeches and a large blister to the loins, lime-water and subcarbonate of ammonia with an animal diet, were first tried, but under this treatment the patient, though somewhat improved in spirits, evidently became worse, and the urinary discharge increased to seventeen pints daily. Although he was now still further reduced, Dr. Kennedy was "firmly convinced that his only chance of recovery was in the bleeding system of Dr. Watt," and accordingly on Sept. 20th began by ab-

stracting twelve ounces of blood from the arm. The relief afforded by this measure was very striking, the headach which had previously been very distressing was almost entirely removed, the patient regained his former cheerfulness, and declared that he felt better than he had done for some years; and the quantity of urine discharged in the subsequent twenty-four hours was only nine pints. On the next day, however, the quantity being again slightly increased, and the headach having partially returned, the bleeding was repeated with the same immediate relief as before, and five grains of blue-pill every other night, with a pint of decoct. sarasp. daily, were prescribed. On the 23d the patient continued better, the urine amounted to only eight pints in the twenty-four hours, and the thirst had altogether ceased. On the 24th the headach and thirst were again slightly felt, the quantity of urine for the twenty-four hours was eight and a half pints. Venesection was therefore again employed, and with the same good effect as on the previous occasions. Between this date and Oct. 14, the bleeding was repeated four times, and always with decided benefit, the urinary discharge gradually diminishing in quantity, and becoming of a more natural quality, and the patient improving rapidly in health and strength, so that by the beginning of November he was completely recovered. The sore from the blister on the loins was kept open during the whole period of treatment, but there can be no doubt that the beneficial result was chiefly, if not entirely, owing to the abstraction of blood.

The following article contains a case related by Mr. Twining, in which he succeeded in reducing a dislocation of the humerus in a robust and healthy sailor, which had existed fifteen weeks, no attempt at reduction having been made. Gradually increased extension with the pulleys was maintained for fifty minutes, and during that time nausea and faintness were induced by a large dose of tartar emetic and the abstraction of  $\frac{1}{2}$ ij of blood. The head of the bone was raised with considerable force from the axilla, and returned into the glenoid cavity suddenly and with a very audible grinding noise. The patient left the hospital only a few days after the reduction, and was then able to move his arm as much as, at that

early period, could be prudently permitted. The following note is appended by Mr. Twining, and we may observe that any information on the subject will be acceptable to us, as we know of no other case where the bone has been reduced at so long a period after the occurrence of the accident.

"The patient, William Foss, returned in the brig Francis to Liverpool, and should he not recover the use of his arm, it is probable that he will apply to a hospital for aid; and any communication as to the degree of his recovery would be interesting to the Calcutta Medical Society."

The 14th article is by the same gentleman on the employment of *Ipecacuanha* in dysentery. From the cases, of which a number are concisely related, this medicine appears to have been most efficacious in the simple acute form of the disease; it was not, however, considered as by any means a substitute for antiphlogistic measures, its administration being always preceded by free general or local bleeding, when the patient was seen soon after the commencement of the disease, or at a later period, when the symptoms indicated the existence of inflammation. It was invariably combined with extract of gentian, and was given sometimes even in twelve-grain doses, without inducing the least nausea. The usual dose was, however, six grains, with four grains of the extract, twice a day; in some cases, where the liver appeared to be affected, it was advantageously combined with blue-pill, in others it does not appear to have been rendered more efficacious by this addition, on the contrary, its good effects were much more evident after the mercury had been omitted. In some cases, which are related by Dr. Mortimer of Madras, the *Ipecacuanha* was given much more frequently, and combined with gum acaciæ instead of extract of gentian; it appears, however, to have been less efficacious in this form, though still of much service. The use of *Ipecacuanha* in dysentery has been long known, but we are not aware that it has been given before in this particular manner, or combined with any medicine which has so completely obviated its nauseating effects, without at all diminishing its beneficial action on the lower intestines.

No. 15 is a case of stone, in which the recto-vesical operation was performed by

Mr. Tweedie, at Rangoon. The patient, a Mussulman boy nine years old, had been afflicted with the disease for about seven years. The stone, which consisted externally of the ammoniæo-magnesian phosphate, and was four inches and a half in length and three and a quarter in circumference, was very easily felt from the rectum; no staff, therefore, was employed, and the sphincter ani was not divided. From the latter circumstance, and probably also from the smallness of the incision into the bladder, though this is not mentioned, some difficulty was experienced in the extraction of the calculus; the operation was, however, completed in about five minutes. Fæces (and even a live round worm, *ascaris lumbricoides*) were passed by the urethra for more than a month; in six weeks, however, the recto-vesical opening was entirely healed, and the patient perfectly recovered. In the appendix, another case of calculus is related, in which lithotomy was performed by a native, who, by his own account, had operated on about 150 patients, and lost only sixteen. His method was that which has been termed the apparatus minor. His whole stock of instruments consisted of an old lancet, a small folding knife, and a piece of unpolished iron, about the size of a common uncut drawing-pencil, having one end coarsely scoop-shaped," and he was "totally ignorant of anatomy, having no rational idea of the parts to be divided, nor of those which would have been endangered by a slip of the knife. Notwithstanding these disadvantages, the calculus was speedily extracted, and the patient, a native boy seven years old, was going on remarkably well on the tenth day, after which he was not seen by the relater of the case. The operation is thus described:

"Without any preparation whatever, nay, allowing the boy to void his urine just before commencing, the operator proceeded as follows, having first gladly accepted a double-edged scalpel as a substitute for his own knife, but refusing forceps of any kind. The patient having been placed on the knees of his father, who was seated on the edge of a cot, with each hand passed under the ham of the same side, and the wrists held in such a position as to draw the knees as far upwards and outwards as possible; the operator knelt before him, introduced the two fingers of the left hand into the anus, and with the right having roughly

pressed above the pubes for a few seconds, brought the calculus to press out the skin of the perinæum to the left of the raphe near the anus; he then boldly cut down on the stone, the incision running nearly in the same direction as that made in the lateral operation, and attempted to scoop it out very roughly with the bit of iron. Having failed in this attempt, at our suggestion he slightly enlarged the wound, and then extracted with ease a calculus of a flattened oval shape, and larger than a pigeon's egg, the whole being over in less than two minutes."

Two cases of hydrophobia are described in Nos. 12 and 16. In the one the extract of belladonna, in the other the superacetate of lead was tried; both cases proved fatal under the usual symptoms. The belladonna appeared to have no beneficial effect whatever. In the second case, the patient, a native boy *ætat.* ten, appeared to improve under the use of the lead, and a blister to the throat, and was able to swallow water with very little effort; unfortunately, however, he was removed by his friends on the second, became speedily worse on the omission of the medicine, and died on the evening of the third. Another case is given in the appendix, of a native girl, nine years old, in whom a very evident beneficial effect was produced by the administration of two large doses of opium; the improvement, however, was only of very short duration; the violence of the disease soon returned, and she died in a few hours.

The twenty-second paper, by Dr. Moust, gives an account of an epidemic cholera which occurred in March, 1828, among the soldiers of a European regiment stationed at Berhampore. It came on suddenly, without any assignable cause, and lasted one month, during which time 27 out of the 132 patients admitted into the hospital died. It is remarkable, that only the European private soldiers, and some native servants and bazaar attendants, were affected; neither the officers, nor any of the sepoys at the same station, were attacked by it. The general phenomena of the disease were nearly the same as those which have been usually observed, but it was characterised by immediate and extreme collapse and prostration of strength, with little or no tendency to reaction. The symptoms of course varied in different cases. The most

usual, however, were "purging, vomiting, pain or heat at the præcordia, anxiety, spasms, restlessness, oppression; cold, damp, clammy skin, collapse, failure of the pulse, shrivelled extremities, and urgent thirst."

"The prostration of strength in every one was a marked feature of the disease. In three or four cases, the depression was the principal symptom on their admission into the hospital, as the slight vomiting and purging which they had could hardly be deemed a disease, though the eventual occurrence of cramps, the nature of the evacuations, and the urgent thirst, but too fully proved it to have been cholera." A tabular view is given of all the cases omitted; but as only the duration and event of the disease, the principal symptoms on admission, and the remedies employed, are stated, little can be learnt from it. Venesection, which was tried in forty-six cases, was of no benefit; on the contrary, it is stated that, in several instances, it was decidedly injurious; and the author observes,

"In no instance, with any of the above symptoms, however slight, or however early in the disease, did the flow of blood either rouse the system, induce reaction, or relieve the complaint. The blood either does not flow, or trickles from the vein, in the usual cases of cholera; here, however, it has generally flowed freely; yet, instead of the pulse rising, faintness, exhaustion, cold sweats, with increase of vomiting and cramps, have obliged us to have recourse to stimulants to rouse the vital energies."

The treatment, therefore, principally consisted in the administration of large doses of calomel with opium, of magnesia and stimulants, as brandy, ammonia, &c., blisters to the epigastrium and bottles of hot water to the sides and feet, which latter with manual friction were found to be of great service.

"On dissection in many cases, very little disease was apparent. In some there was much congestion and vascularity, in others very little; every case was minutely examined, and with the exception of the vessels of the head, brain, lungs, liver, stomach, and intestines, appearing turgid, and sometimes loaded with blood, there was nothing observed worthy of record."

The account of this epidemic affords proof, if indeed proof were wanting, of the justice of our observations in a recent number, on the disease now raging in Russia, and of the absurdity of attempting to lay down any me-

thod of treatment which shall be applicable to every form of the disease.

The last article which we shall notice is by Mr. Raleigh, and contains an account of three cases of cataract in which the operation of extraction, though perfectly well performed, was not succeeded by sufficient inflammatory action. In the first case there was no reproduction of the aqueous humour, though the edges of the incision remained in close connexion; the cornea slowly became flaccid, dim, and opaque, and ultimately the whole globe sank without any suffering to the patient. In the other two cases a similar want of action was remedied by the application of pepper, and of a solution of nitrate of silver to the surface of the eye; and a moderate degree of inflammation having been set up the curative process proceeded, and vision was completely restored. All three patients were natives, and each was about fifty years old. Though not robust they appeared in tolerably good health at the time of the operation.

*Elements of Chemistry.* By ANDREW FYFE, M.D.F.R.S.E., Lecturer on Chemistry, &c. &c. Edinburgh: Black. 1830. 8vo. pp. 1062. 2d Edit.

[The first edition of this work was published in two volumes; in the present edition the two volumes are bound together.]

Of the numerous systems, elements, and manuals, of chemistry, which have appeared within the last few years, that which is now before us is decidedly one of the best. Indeed we know of no work of similar extent which can be placed before it, either for general accuracy, quantity of information, or clearness and conciseness of style.

The arrangement, which differs considerably from the order which has been hitherto generally adopted, is according to the most recent views of the first chemists, both English and continental, the discoveries and opinions of whom, Dr. Fyfe has examined and collated with much diligence and ingenuity. Instead of dividing simple substances into positive and negative, or into combustibles and supporters of combustion, he has arranged them as acidifying and alkalifying principles, and acidifiable and alkalifiable bodies, using the term alkali in

a very extended sense, to denote all those substances which are capable of forming salts by their union with acids. In the first division only two substances are included, oxygen and hydrogen. In the latter, chlorine, fluorine, azote, and all the simple combustibles, or electro-positive bodies. In this arrangement it is evident that in muriatic acid, hydrogen and not chlorine is considered as the acidifying principle, a theory which is certainly well supported by analogy, since, on the one hand, in hydrocyanic acid, and in hydrothionic acid, or sulphuretted hydrogen, the former gas performs the same part that oxygen performs in nitric, carbonic, and the other oxy-acids; and, on the other hand, chlorine must be regarded as the base in chloric acid, and its compounds, with the alkalies, metals, &c., appear to be more analogous to those of the same substances with sulphur and carbon, than to the oxyds with which they have generally been compared. Of course the same arguments apply in a still stronger degree to the other two supporters of combustion, iodine and fluorine. As our object here is rather to point out the nature and value of the work than to give an analysis of it, which could be of little or no use to our readers, we shall not enter further into detail. We have only to state that the principal part of it, which contains some account of every known substance, natural and artificial, which can be treated of in a work of this kind, is preceded by much valuable information on the subjects of heat and attraction, and some brief, but very instructive, observations on light, chiefly in reference to its chemical effects, and followed by a long and interesting chapter on electricity and galvanism,—by another, equally valuable, on analytical chemistry, referring chiefly to the composition of mineral waters, and the examination and detection of poisons, and by many useful and accurate tables, which it is unnecessary for us to enumerate. The typography is, throughout, remarkably correct; but we know not why the author has chosen to write *origen* and *oxid*, instead of *oxygen* and *oxyd*, which are sanctioned not merely by custom, but also by the derivation of the words.

## MANSLAUGHTER

COMMITTED A SECOND TIME BY

JOHN LONG.

At 11 o'clock on Wednesday, Nov. 10, a jury assembled at the Wilton Arms, Knightsbridge, to inquire into the death of Mrs. Colin Campbell Lloyd, aged 48, the wife of Captain Edward Lloyd, of the Navy. The jury proceeded to view the body of the unfortunate lady, at her lodgings, No. 33, Wilton-place, and on their return the following evidence was adduced:—

*Mr. George Vance*, surgeon: I visited Mrs. Lloyd on the 21st October last, which, as I was informed by her medical attendant, Mr. Campbell, was about ten days from the commencement of her illness. Mrs. Lloyd informed me that she had inhaled, from a tube, a few times at Mr. St. John Long's, and had been rubbed on the chest with a liniment twice; the first rubbing, she said, produced no inconvenience, but the second a sense of burning heat; she stated that she was quite well at the time, and had not suffered any important indisposition for three years; from the inhalation, it appeared to me that her tongue, mouth, and fauces, had eroded; on examining her chest, where she had been rubbed, I found a sloughing sore of great extent, which extended from the armpits across the chest in one direction, and from the collar-bones above, under the nipples, in the other direction; in the middle of this sore, the soft parts covering the breast-bone were black and dead, but towards the circumference there was a little appearance of health, and the mortified parts were separating from the living; the stomach was much disturbed, and she was in a state of great exhaustion and despondency, frequently expressing a desire to die. In a day or two after my attendance, some of the constitutional distress subsided, and her spirits revived; the dead parts began to separate more freely: no granulations, however, appearing in the clean parts of the sore, and the surface having become dry and flabby, exhibited the appearance of the dissected parts of a dead body. Mr. Campbell, a surgeon, and myself, removed masses of putrid flesh. The breast-bone was found bare, and I believe that if the slough had been freely thrown off, the cartilages of the ribs would have been exposed also. The deceased gradually grew weaker, and died on Monday morning the 8th of November. The application of some corrosive matter applied to the parts, which I found in a state of mortification, was the cause of her death.

*Mr. Brodie*, surgeon, sworn: I saw Mrs. Lloyd last Friday week, with Mr. Vance. The witness confirmed the evidence of Mr. Vance. I should think that any mineral acid, or arsenical application, would produce such an effect; I do not remember having seen the same mischief produced by any local application that had been used as a remedy, excepting in the case of the late Miss Cashin.

Cross-examined: In some cases the applications in common use produce effects more violent than in other cases, and beyond what the practitioner may have intended.

*Mr. Campbell*, surgeon, said: About the 1st of October, Mrs. Lloyd and her family came on a visit to my mother's house, and she appeared to be in sound bodily health. On the 12th of October I was requested to see her, as she was dangerously ill. She complained of pain on her chest, on examining which I found the wound which has been described. Mrs. Lloyd stated to me, that she had consulted Mr. St. John Long for an affection of the throat, a few days before, and he told her that the affection of the throat arose from extensive disease of the lungs—they being full of small ulcers, and recommended her to inhale, which she did for a few days previously to her being rubbed at his house, which took place on the 10th and 11th of October. I have heard the evidence of Mr. Brodie and Mr. Vance, and concur with them in opinion as to the cause of her death. Mrs. Lloyd had no symptom whatever of disease of the lungs; the wound extended twenty inches in length, independent of the inflammation which extended over the abdominal muscles, all down her sides, over the hip and over the shoulder.

Cross-examined. There was no mortification on the wound when I was first called in to attend her on the 12th October; she then told me that she would not allow Mr. Long to come into her presence again, and from that day he never saw her.

*Captain Lloyd* came to London with his wife on the 15th of July; Mrs. Lloyd was in good health; she continued in good health until she became ill from the rubbing of Mr. Long. On the 5th Oct. I accompanied her to Mr. Long's; she went on the following day, when she inhaled. On the 7th she inhaled again; also on the 8th; she went to him on the 9th, when she was rubbed, for the first time, across the bosom, as she described to me; on the 10th Oct. she told me that she had inhaled as before, and afterwards was rubbed—as they termed it, “rubbed out.” She became so unwell while the rubbing was going on, that the rubber was alarmed and went for Mr. Long, who did not come for some time, and when he did, he said it was nothing, and would soon

go off, which it did after some time; but an odd sensation remained which continued during the evening. She passed a restless night, and on the morning of the 12th of October, on looking at her breast, it appeared to me that from lying on her back, wherever the matter discharged from the wound rested, it caused fresh blisters, some of which I cut to relieve her pain. A wicker cradle was made to place over her to prevent the bed-clothes touching her. On this day I called upon Mr. Long, who expressed his surprise at not having seen Mrs. Lloyd to go on with her inhaling. On explaining her inability and great sufferings, he said that he would come in the evening, which he did, and found that she had applied some common blister dressing to alleviate the heat and burning sensation. Mr. Long said that was wrong, and contrary to his practice, but he would "rub it out," which Mrs. Lloyd exclaimed against, saying that she had suffered so much that she could not endure these parts being rubbed at all; the very idea of touching them, even by herself, was excruciating. Mr. Long said, that the only thing necessary to be applied to the wound was old dry linen, to absorb. He then asked for a towel, and began rubbing it dry on the large black spot, as I suppose to absorb the discharge. Mrs. Lloyd said she had always healed any little blister by a simple blister-dressing; and Mr. Long said he saw no objection to her using it, and then departed.

[The inquiry was here adjourned to the following day, when there was called—

*Mrs. Elizabeth Campbell*, sworn and examined by Mr. Wheatley: I remember the day when Captain and Mrs. Lloyd came to my house; I considered her to be in perfect health, with the exception of a little irritation in the throat occasionally; after she had been two or three days in my house, she informed me that she had been to Mr. St. John Long, and had seen several ladies inhaling there. She told me some time after that she had been rubbed; after she had been some time in my house I perceived that there was some alteration in her health—not, however, immediately after she had been rubbed, which operation, she informed me, was first performed on Saturday, the 9th of October; she was quite well that evening, and in very good spirits; she played at cards, and with her children; on Sunday morning she still appeared very well, but in the evening she complained to me of great coldness and a shivering which had come on her; she was, on this complaint being made, put into a warm bed, but she continued in that cold shivering state for many hours.

Mr. WHEATLEY. Do you happen to know that she was rubbed on the Sunday morning?

Witness. Yes; I was given to understand from herself, that she had been "rubbed" on the Sunday morning. She never rose from her bed after she had taken to it on Sunday evening; was removed to another bed; I frequently attended her after that, and never saw any one in so much pain, or suffer so dreadfully, from the Monday morning up to the time that she died; her sufferings are too dreadful almost to think of, and at times she was rendered delirious; she expressed great dread of Mr. Long, and, as a proof, she always fancied from her dread that he was in a large trunk in the room; she often desired the nurse to lock it and hide the key. She suffered so much that Captain Lloyd went to Mr. Long, and he, in consequence, came to the house on Tuesday evening. Mr. Long said she was doing very well, and looking very well, and asked her what she wished to be done. He did not restrict her diet, nor give her any medicines internally. This was the last time that Mr. Long saw the deceased; he called the following day, but the deceased desired that he might be told that she was asleep, for she would not see him; she gradually became weaker and weaker; her sufferings were beyond any one's belief—they were dreadful; she died November 8th.

The remainder of this witness's evidence fully confirmed that of Captain Lloyd.

*Mr. Vance* put in the following report written by him and three other medical gentlemen who examined the body:—

"The surface of the body did not exhibit any appearance of disease, except a gangrenous ulcer on the chest, which we measured, and found to extend from one armpit to the other, a space of sixteen inches; and from the neck downwards to the parts below the nipples, nine inches. The mortified parts being removed, the collar-bone and some of the cartilages of the ribs were bare. The body generally unusually fat.

"On exposing the structures contained in the chest, the lungs were ascertained to be perfectly sound, free from any adhesion to the neighbouring parts, and there was not even a spot that could create the suspicion of disease either on their surface or internally. The heart and all its appendages were also quite healthy.

"The liver, spleen, stomach, and intestines, as well as all the other structures in the abdomen and pelvis, were in a state of perfect health. On the right side the thyroid gland was inflamed, and the structure a little changed from its contiguity to a deep part of the ulcer, but the other part of the gland was healthy. On examining the wind-pipe, no disease appeared, but the portion nearest the ulcer was much inflamed on its inner and anterior surface, and its vessels were full of blood. The œsophagus, which

became the subject of our particular attention, on account of the globus hystericus, was quite healthy, but a little narrow at the upper part, which we are disposed to consider congenital rather than a mark of disease, as there was no thickening nor stricture. We have further to add, that in our professional researches, we have seldom seen a body that had lived forty years, with internal structures so generally healthy, and so fine in their proportions. The head, by the desire of the jury, was not examined, as it had never appeared to be the seat of disease."

*Mr. Vance*, in answer to a question put by the jury, stated, that coughs generally attended inflamed lungs. Counter-irritation moderately applied, and under certain circumstances, was certainly not productive of harm.

*Cross-examined*: A common blister frequently produced mortification.

After *Mr. Campbell* had shortly stated the treatment which he had pursued towards *Mrs. Lloyd*, and which was described by *Mr. Vance* as perfectly correct, the coroner read over the whole of the evidence to the jury.

*Mr. Wooler* then said, that the present question was a very important one, as it affected *Mr. Long* and the public. As such, he thought that every thing that could throw light upon it should be received. He was about to ask the court whether it would permit the evidence of witnesses, as to the nature and character of *Mr. Long's* treatment. He did not mean to ask many questions of them, but simply two or three, in order to show how perfectly innocuous it was. It would then be for them to say, whether blame would be attached to *Mr. Long*, if it had proved of so much benefit to others, and had only failed in one instance.

The Jury unanimously said here, that they thought such evidence was quite unconnected with the case; and one juror inquired if he were prepared to show that the same treatment and the very same lotion had been used towards the deceased as with all the other persons?

*Mr. Wooler* said he could not call evidence certainly to that particular fact, only to his general practice.

*Mr. Wheatley* said, that that question had saved him a great deal of trouble. He observed at once how unnecessary such evidence was. The embrocation might be perfectly innocuous in one instance, and arsenical in the other.

The Coroner observed, that if they allowed such evidence on one side of the question, they must allow contrary evidence on the other, to show that the treatment had not proved efficacious. Besides, he did not see that either way it

could apply to the present case, as they were only sent to inquire into the death of one particular person, and not the deaths or treatment of others.

*Mr. Wooler*: Very well then, I shall only call two witnesses to facts immediately connected with the deceased.

*Mrs. Jane Macdougall*: I am a relation of the deceased; about ten days previous to the 4th of October last, one Sunday, the deceased came into *Mr. Long's*, where I happened to be at the time; she said to me, in the presence of *Mr. Long*, that she had been suddenly taken ill in the street, and that she would be obliged if she might sit down in the hall; she was so very ill that she was afraid to go further, and she did not wish to go into the house, as it would be said that *Mr. Long* had killed her; she told me that she laboured under an affection of the throat, and that *Mr. Vance* had applied caustic to it; about a week after this I saw her at *Mr. Long's*; she appeared to be very much oppressed indeed; she then went in to inhale with the rest of the ladies; she afterwards went down stairs, and had an application made to her throat, from which she told me that she had derived very great benefit; the following day, Sunday, she again came and inhaled, besides having an application made to the throat; I did not see it, but she put her hand to her throat, and said to me, "I have had an application made a second time here;" it might have been lower for what I know, but I thought it must have been there, as she had spoken of the ulcerated throat; she came up stairs immediately after it, and told me that she felt better for the application. I myself have been a patient of *Mr. Long*, and have felt great benefit from the course of treatment; I have always known those who were under *Mr. Long* much benefited.

*Cross examined*: I have been staying at *Mr. Long's* house for ten days with a cousin of mine; I have known him since last December.

The colour of the liquid was milk-white.

By a Jurymen: The lotion was always of the same colour; I have been rubbed in the chest, but no discharge took place, unless the part affected was rubbed.

By a Jurymen: The caustic which the deceased said had been applied by *Mr. Vance* was applied about two or three years ago.

The Jury said that this fact was very important after what had been stated by the witness before; they had thought then that the application of the caustic was only a short time prior to her going to *Mr. Long*.

*Miss Gertrude Smith*, of No. 4, George-street, Hanover-square, was next sworn: I knew the deceased; about two months since I met her first at *Mr. Long's*, Harley-street; she said she came to him for an inflamed

sore throat; the witness then confirmed the statement of the last witness as to the deceased coming into the hall, and not wishing to go into the house, for fear that if she died it should be said that Mr. Long had murdered her. Witness then said, I saw her afterwards, when she had been under the care of Mr. Long, and had felt great benefit from the treatment of Mr. Long.

Cross-examined: I am a confidential friend of Mr. Long; he does not tell me what is the matter with all his patients, but I asked him in this instance; my sister and my cousin have derived the greatest benefit from Mr. Long's treatment, the first, in fact, was restored to life by him; Mrs. Lloyd appeared, when I first saw her, to be very bad indeed; I do not think that she could have walked five miles; she was not an emaciated-looking person, but she was very pale, except when a hectic colour spread over her face; she walked accidentally into Mr. Long's house, I suppose, and she then made the remark about the murder [cries of "Quite enough, quite enough"]; I know that Capt. Lloyd was a very great friend of Mr. Long [buzzes of surprise]. At the time that Mrs. Lloyd walked into the house of Mr. Long by accident, Mr. Lloyd was in a room up stairs. On a servant informing him of this, and the sudden illness of his wife, he sent word that she was to come up stairs. The deceased told me that she had not intended to come in if she had not been seized with illness. Mr. Long is not married.—This witness's latter evidence excited a great deal of surprise.

The CORONER then addressed the Jury, and told them that the time had at length arrived when it was their duty to take into their serious consideration the evidence that had been produced before them touching the death of the deceased Mrs. Lloyd. The case, in his opinion, could be brought into a very narrow compass. The matter, in his view, for their determination was, whether the deceased died a natural death, or in consequence of the gross ignorance of the medical man who attended her. If he had been either grossly ignorant or inattentive, he was then guilty of the crime of manslaughter.

[The Coroner said he would go through the whole of the evidence if it were required, but the Jury said that they were satisfied with what they had heard already.]

The Jury after this retired for a short time, and then came in with the following written verdict:—"The Jury, having attentively considered the evidence that has been before them, can come to no other verdict than that of *Manslaughter* against John St. John Long."

The CORONER then said, that in order that he might draw up the document before

him properly, he should wish to know on what grounds they returned their verdict?

The Foreman of the Jury said, on the principle of gross ignorance. They said nothing about inattention, as there had not been time between the treatment prescribed and the death of the deceased. The Foreman added, that they had drawn up a Protest, which they wished to be made public. He then read as follows:—"The Jury, in delivering their verdict, think it an incumbent duty on them, on the present important and melancholy occasion, of stating it as their solemn conviction, that the time was now arrived for the Legislature adopting immediate measures to prevent any further sacrifice of human life, by stopping persons from acting as surgeons who were not duly qualified to act as such."—(*Loud applause.*)

The FELON has not yet been taken; it is supposed he has quitted the country.

## MEATH HOSPITAL.

*To the Editor of THE LANCET.*

SIR,—Inclosed I send you the verbatim copies of two cases which were admitted into the Meath Hospital, under the care of my esteemed friend Rawdon M'Namara, Esq., and which were transmitted to me by J. Harris, Esq., of Camden Street, Dublin. Should you, on perusal, deem them worthy of a corner in your talented and widely-circulated Journal, I think you will confer a favour on the profession at large, by giving publicity to reports of such highly interesting and practically important cases.

I am your well-wisher and admirer,  
ARTHUR BRETHAM.  
Stoke Newington, 11th Oct. 1830.

## GANGRENOUS ERYSIPELAS.

CASE.—James Keough, a sawyer, *stat.* 34, became a patient of Mr. M'Namara in the Meath Hospital, in consequence of gangrenous erysipelas, which destroyed the whole of the integuments of the arm, forearm, and a portion of those of the hand; he was suffering from hectic in an extreme degree, with a quick, small, and very irregular pulse; indeed so far were the powers of life reduced, that the proposal of removing the arm at the shoulder-joint appeared to many a very hazardous measure, an opinion that, I confess, I agreed in, seeing how small a quantity of blood, the loss of which would be sufficient to deprive such a patient of life, an opinion that was strengthened by the length and severity of two operations I had seen elsewhere performed.

The patient was carried into the operat-

ing theatre in his bed, on Saturday the 18th of Sept. last, and having been placed sitting on the side of it, Mr. M'Namara commenced the operation, by making a flap of the deltoid muscle, in the manner recommended by De La Faye; he then cut into the joint, dislocated the bone, and finished the operation by bringing out his knife behind the bone, making the inferior flap by one stroke of the instrument. The axillary artery, the circumflex arteries, and one or two inconsiderable vessels, were now secured, and the flaps were brought together by means of adhesive plaster and sutures. An anodyne draught was administered, though I could not say that the patient suffered extreme pain either during the operation or after it; indeed his sufferings were of so short duration, the cutting part occupying but a minute and a half, that I think I am warranted in saying, that amputation at the shoulder-joint is attended with as little pain as a common amputation, and (if I am to judge from the present case, which undoubtedly was a good specimen of Irish surgery), with certainly less hæmorrhage, in so much that more than two ounces of blood were not lost on the occasion. It is also worthy of remark, that the axillary vein did not bleed.

It is unnecessary to occupy your valuable space by a detailed account of the treatment, which did not embrace any-thing out of the ordinary course pursued in such cases; the man has hourly gained strength; the ligatures have all come away; and the wound is now, ten days from the operation, nearly healed. There are one or two observations with which I shall trouble you on the present case; and first, it is obvious how much the debility here may, relatively, be produced by the presence of an extensively suppurating surface, over which the constitution was incapable of exerting any salutary control; secondly, how little we should permit ourselves to be influenced by this apparent debility, which will certainly disappear as soon as its cause is removed; thirdly, how unnecessary the tying of the axillary artery or vein is, as a preliminary step to the performance of the operation; and, lastly, how uncalled for is the removal of the cartilage from the glenoid cavity, a practice which has been adopted from the fear of the occurrence of subsequent inflammation and disease, which, from a reference to this and other cases, I am warranted in saying never occur.

#### ŒDEMA OF THE LARYNX.—TRACHEOTOMY.

William Kenny, aged 47, of a bilious temperament, admitted on the 16th Sept. stated, that about three o'clock on the evening before, he had been attacked by a rigour, which was succeeded by sore throat; that

previous to this he had always enjoyed good health, with the exception of a slight pulmonary catarrh of some years' standing; that at midnight he awoke, unable to swallow; his breathing extremely difficult, noisy, and accompanied by a slight cough. For the relief of these symptoms he used a muriatic acid gargle. Present state: voice husky in the highest degree; breathing deep, slow, remarkably loud, and attended with considerable mæco-sibilous râle, cough, accompanied with mucous expectoration; deglutition impossible, as far as regards solids, and a considerable portion of any fluid was even regurgitated through the nares; the larynx very tender upon pressure; 28 ounces of blood were immediately drawn from the arm, and he was ordered to take two grains of tartarised antimony every hour in solution. Noon; breathing less loud; pulse 128, soft; skin moist; has vomited frequently some bilious matter; his condition, however, is not improved. Seven o'clock P.M.; oppression of breathing so great, that the patient expressed himself incapable of existing; cough troublesome; stridulous respiration increased considerably; pulse quick; extremities cold; upper part of the body bedewed with sweat; integuments of the neck considerably swollen from œdema; deglutition entirely obstructed. On examining the fauces, Mr. M'Namara discovered a tumour of the size of a large walnut, formed by the integuments of the epiglottis, which had become œdematous, and from its situation capable of completely obstructing deglutition whenever the patient made an effort to swallow; it did not, however, obstruct respiration, inasmuch as it stood erect in the fauces, and could not be laid down upon the rima glottidis; it however followed the motion of the tongue, and thus became an impediment to deglutition when that organ was moved backwards, occupying the pharynx, rendering it impossible for food to pass downwards. Considering that the integuments of the other parts of the larynx were in the same state, and the man must be suffocated if some effort were not made to admit air to the lungs, Mr. M'Namara determined upon performing the operation of tracheotomy immediately. The patient having been properly placed, and the usual incision made in the integuments, the trachea was now laid bare at a depth of fully two inches and a half below the surface; to such an extent had the œdema proceeded; the tube was easily perforated, but on endeavouring to turn the knife in order to enlarge the wound by dividing the cartilages, he found it impossible, without risking the breaking of the instrument, as they were ossified; he therefore enlarged the wound with a pair of scissors, the rings of the trachea giving au-

dible evidence of their ossification on being cut through; there was not any bleeding of consequence during the operation, and the man was put to bed expressing how completely he felt himself relieved. He was ordered four grains of calomel every second hour, and to inhale the steam of warm water during the night.

17. The patient breathed partly through the wound and by the larynx; the croupy sound of respiration lessened, and deglutition gradually improved; swelling of the epiglottis much less; pulse 112; respiration 24; skin moist; bowels moved; no thirst; tongue clean, and no appearance of pyalism, though half a drachm of calomel had been taken during the night. Repeat the calomel. A silver tube was placed in the wound.

18. The respiration was natural; the tongue clean; pulse 90; bowels moved three times; the epiglottis has subsided to its natural size; integuments of the neck also much less; had some sleep during the night; the calomel was now discontinued, and he was ordered a draught, consisting of an ounce of the infusion of roses, a drachm of Epsom salts, and the same of tincture of jalap.

It is unnecessary to report further on this case, inasmuch as he is rapidly improving, complaining of no inconvenience but what results from the soreness of his mouth. The tube he occasionally introduces himself, and there is every reason to think that he will be able shortly to relinquish it altogether; nor need I impress upon you, Mr. Editor, the advantage of an early operation in cases of oedema of the larynx.

## DUBLIN COLLEGE OF SURGEONS.

### DISGRACEFUL BY-LAWS.—PATRIOTIC RESIGNATION OF MR. CARMICHAEL.

#### *To the Editor of THE LANCET.*

SIR,—In my reply to the unfounded attack upon Mr. Carmichael, on account of his wise and laudable exertions to improve the system of government in the Irish College of Surgeons, inserted in your 355th number, I stated in proof of that gentleman's liberality that he was engaged at the time I wrote, in an attempt to annul the disgraceful system of by-laws, enacted by a faction in the name of the College, respecting the qualifications of candidates for examination, which were so constructed as to force every pupil to become an apprentice for reasons too obvious to require explanation. This barefaced attempt to turn the liberal provisions of a charter into a source of private emolument,

met with the lashing it deserved in your independent publication, and Dr. Johnson also, in his quarterly journal, designated this code of laws, a disgrace to the nineteenth century. I mentioned in my reply alluded to, that knowing well the *material* of which the present reigning faction of the College is composed, and the lamentable indifference of others, I was not very sanguine as to Mr. Carmichael's success; and I promised to let you know the result, which I now proceed briefly to do, merely stating facts without either note or comment, upon matters which speak for themselves.

The committee deputed by the College on the motion of Mr. Carmichael, to reconsider the by-laws in question, consisted, with the exception of that gentleman, of the same individuals who originally framed them, an arrangement which was not of a very promising appearance.

The committee frequently met, but proceeded at the pace of a snail, for the first question to be decided included the very pith and marrow of their business; viz., whether or not the precisely same system of education and the same expenses should be imposed upon both apprentices and non-apprentices. This was at length determined in committee in the negative, notwithstanding the unanswerable arguments of Mr. Carmichael and Mr. Harrison. The former, as a last effort, then applied to the College to have the committee enlarged. At a meeting of the College convened for the purpose of taking his request into consideration, it was refused on pretence of irregularity, which induced Mr. Carmichael to resign his seat as a member of the committee, stating that he considered the business of it to be already at an end, and that any further attempt on his part to repeal the obnoxious by-laws must be unavailing, since the meeting did not deem it right to augment the committee.

On the 22nd of July the committee made its report after sitting several months, and it may be said, virtually confirmed the by-laws as they previously existed; for alterations such as, that in place of the word "hospital," "some hospital or county infirmary" be inserted, and other fiddle faddle of the same description, could only be propounded to blink the question.

This report having been received and agreed to by the College, it met again on the 16th of September to confirm or reject the proposed alterations, when, on the question being put, Mr. Harrison, whose liberal and strenuous exertions to abrogate these abominable laws cannot be too highly extolled, moved as an amendment, "That the apprentice shall lay before the court a letter or certificate from his master, stating that he has attended the surgical practice of a hospital or county infirmary; that he has

also attended lectures on anatomy and surgery, practice of physic, chemistry, materia medica, midwifery, and medical jurisprudence, and that he has also attended demonstrations and dissections, and pursued his professional education conformably to his master's directions."

This, however, was negatived, as well as the following addition of Mr. Carmichael, "That the court of censors be requested to issue annually to the members and licentiates a circular letter, notifying that the court will expect that all apprenticed pupils shall conform to the routine of education laid down for non-apprentices, but that, as a regular apprenticed pupil has the advantage of the master's instructions, the same number of certificates may not be required as for non-apprentices." This amendment was negatived by 18 to 12. Even this moderate improvement, which may be considered in the light of an apology for the apparent partiality of the by-laws, the meeting had not the good sense to adopt, and it finally received and confirmed the report of the committee, and thus ratified the continuance of the obnoxious by-laws, without any beneficial alteration. I shall conclude this statement of facts, by annexing a copy of a letter from Mr. Carmichael to the President of the College, resigning his seat in the court of assistants, which was read at the last quarterly meeting held on the 1st of this month.

"Rutland Square, Nov. 1st, 1850.

"Sir,—I deeply regret that the by-laws respecting the qualifications of candidates for letters testimonial, have been confirmed by the College at its last meeting, although during a protracted discussion of several days, sufficient facts and reasonings were adduced to convince any unprejudiced mind of their partiality, injustice, and direct violation of the spirit of our charter. I therefore, Sir, feel myself under the necessity of resigning my seat as a member of the Court of Assistants; for, to hold office after the failure of every possible exertion to repeal those obnoxious by-laws, would be justly considered a tacit approval of their continuance, and of the councils by which the College has been for some time directed, and which, to say the least, I cannot consider but as short-sighted, imprudent, and directly opposed to the honour and dignity of the College, which every member on admission pledges himself publicly and solemnly to uphold to the best of his abilities.

"Our new charter has opened two distinct roads by which a license to practise surgery in Ireland can be obtained; the one by apprenticeship and conformity to a certain system of education, which, in the words of the charter, is to be "hereafter

laid down by the College;" the other merely consists in a conformity to the system of education, but without an apprenticeship. Now the College has, in my apprehension, unfairly taken advantage of this unfortunate word "*hereafter*," and instead of laying down one system of education for both classes of pupils, has enacted a distinct system for each, and this is done in such a manner as must convince any disinterested person who peruses the by-laws relating to this subject, that the object of the College is to discourage all pupils from entering into the profession by any other route than that of an apprenticeship. It therefore follows that the non-indentured candidate will enter on the ordeal of an examination, with an impression that he is about to stake his reputation and future prospects in life before a prejudiced tribunal, against whose prepossessions he can have no other dependence save the publicity of his examination, which wise precaution, however needful, will not remove from his mind a conviction, that he goes to trial before judges impressed with a belief that they will serve themselves by his rejection.

"It was for the purpose of removing altogether these objections, that I moved for a committee to reconsider the by-laws in question, for I shall venture to assert that there is not a member of the College who has more at heart its true interests than myself, and it is with regret that I feel myself compelled to resign all connexion by office with a body to which I must naturally be attached, were it only by habit, being a licentiate or member for upwards of thirty years, during twenty-six of which I successively held office either as a member of the court of examiners, or court of appeal, or as vice-president, or president of the College.

I have the honour to be, Sir,  
Your most obedient and very humble servant,  
RICHARD CARMICHAEL."

The close and pungent reasoning of this letter, and its so unceremoniously holding up in their nakedness the dishonesty and selfishness of the faction, to the scorn of the College and the public, drew down a torrent of the coarsest and most outrageous abuse from Dr. Jacob, who was absolutely frantic. He did not make the slightest attempt to disprove a single argument in the letter, but recommended, 1st, that a vote of censure should be passed on it, and, 2dly, that it should be returned to Mr. Carmichael, concluding with a prediction (under the irresistible influence of which I write), that it would be published in *THE LANCET* in ten days—a foolish prediction, serving only to reveal that *the jade is galled*, and where. Why does Dr. Jacob *wince* at thought of

the publicity of Mr. Carmichael's letter? He can reply to confute its calumnies publicly, and I (encouraged by his success in prophecy) *predict* he will not. A spirited and admirable defence of Mr. Carmichael's letter by Mr. Harrison, in which he pledges himself to bring the subject of it again and again under discussion, had the effect of completely foiling Dr. Jacob's attempt to induce the College to censure or insult Mr. Carmichael, for having put on paper opinions and reasonings which he had repeatedly and as strongly enforced in person at the meetings of the College.

One prediction more and I have done. The College has notoriously lost character by the disgraceful squabbling which has taken place lately at its meetings, on the part of men utterly regardless of, and ready at all times to sacrifice, its honour to the defence of their own perquisites. I *predict* that it will not recover what it has lost, by suffering to pass without censure Dr. Jacob's frothy and vapid abuse of Mr. Carmichael, a member, who has so largely contributed to maintain and raise the respectability of the Irish College, by writings, which are better known in Berlin and New York than Dr. Jacob's are in Ely Place. Dr. Jacob expressed himself distressed that Mr. Carmichael did not present himself in person to offer his resignation and his reasons for it. Even here, however, Mr. Carmichael was right. He consulted his own dignity in declining to enter the lists with a person who could forget that he was a member of an honourable profession, and was ignorant of the use of such language as flows from generous principles and gentlemanly feelings—a forgetfulness and an ignorance abundantly evinced on the present occasion.

I remain, Sir,

Your most obedient humble servant,

A. B.

Dublin, Nov. 6, 1830.

## ST. THOMAS'S HOSPITAL.

### CLINICAL LECTURE

DELIVERED BY

DR. ELLIOTSON,

Nov. 8, 1830.

#### VARIOUS CASES.

#### HOSPITAL REGULATION RESPECTING POST-MORTEM EXAMINATIONS.

DURING the last week, Gentlemen, that is, since the commencement of the present month, eight patients have been admitted,

five of them men and three women. The cases among the women were, one of phthisis, one of epilepsy, and one of rheumatism. Amongst the men were, one case of paralysis of the wrists from lead, one of acute inflammatory dropsy, one of colic from lead, one of chronic diarrhoea, and one of inflammation of the glands at the angle of the jaw.

Since I last saw you, four patients have been presented, three women and one man; among the former was a case of chronic bronchitis, one of rheumatism, and one of continued fever; the man's was chronic rheumatism.

The case of chronic bronchitis occurred in a girl, and had existed two years, having arisen from measles. You are aware that measles often leave chronic inflammation of the mucous membrane of the bronchiæ, and very frequently give origin to tubercles in the lungs: in this instance the former affection was produced. By moderate diet—nutritious but not stimulating—an emetic of ipecacuanha every other morning, and a small dose of ipecacuanha and opium every evening, she soon got so much better that I was able to present her. The case of fever was slight, and yielded to the usual remedies. The rheumatism of the man was cured by mercury, and the application of a cold lotion to the parts affected when too hot. The rheumatic pains were situated chiefly in the knees and shins, and were so severe that he said he felt as if "rats were gnawing and gimlets boring." The affection was attended with great heat, and became worse when the parts were covered with warm clothing, or placed near the fire. An evaporating spirit lotion was applied cold, whenever the parts felt to him of morbid heat, and he took three grains of calomel and fifteen grains of the compound ipecacuanha powder every night, till his mouth became sore, when the pains instantly left him; and he continued a fortnight afterwards in the hospital without any return.

There has been one death. The patient was a woman, and the case one of apoplexy. There was, I am sorry to say, no inspection of the body. It is much to be regretted that in this hospital we cannot inspect patients who die without having first obtained permission from the friends. Frequently a patient dies here in whose case we have for months used the utmost efforts to cure or relieve, and make an accurate diagnosis, and then no opportunity is given of proving the correctness of the diagnosis. I am quite satisfied that if patients or their friends were informed that people would not be admitted into the hospital, except in cases of accident or sudden illness, unless permission was previously given to inspect the body in the event of death, they would consent to it, and it would be done as a matter of course.

Under the present circumstances, in a large number of instances, when permission is at first refused, it is given as soon as we offer money. But this is a bad habit, and I seldom yield to it. Again, in a large number of cases, the persons who refuse permission are not the immediate relatives, but mere acquaintances; and though the former would consent, the latter urge them to oppose the measure, for the mere purpose of looking friendly, or exerting influence and being busy. It frequently also happens that patients are never visited while in the hospital by either relatives or acquaintances, so long as they are alive, but as soon as they die, ten or twenty persons come forward to prevent the body from being opened. I am quite sure that if it were made a rule to admit none (except indeed urgent cases) but with the understanding that they should be opened if they died, it would be cheerfully assented to. I am satisfied that the public feeling would change on the subject,—that the world might be brought to consider that we had not paid proper respect to the deceased unless we had ascertained by examination after death, the precise nature and cause of the complaint, and communicated the true state of the inside to the friends. This is always done in the case of the highest personage of the kingdom; and every soldier is opened, and whatever may be the part of the world in which he may have died, an account of the inspection is transmitted to the army medical board at Woolwich. Unfortunately, many do not distinguish between dissection and inspection—do not know that while dissection means cutting up piece by piece, inspection is merely making a cut, looking in, and sewing the cut up again. Whenever I die I hope to be carefully inspected.

## FEIGNED CONVULSIVE DISEASE.

One patient has been expelled who was admitted during the last month, and whom I dare say every gentleman saw. The case was that of a man who said he was 25 years old, and that he had been ill five months only. His complaint, or his *alleged* complaint, was a violent agitation of the body whenever he attempted to stand. When on his feet, he stood upon his toes and kept going up and down in a violent manner, till he seemed like a frantic person, and was obliged soon to sit down from the violence of the motion, and the moment he sat down again, his feet began to beat rapidly on the floor. I never saw a case of this kind before, and strongly suspected from the first, as every one must who saw him, that this statement was mere fudge, and that he was an impostor. On making inquiry into the history of the alleged complaint, he informed me that after having got dead drunk one

night, he found himself the next morning unable to move from numbness and debility. That a month passed over and he was no better, but on any attempt to walk or to stand upon the lower extremities, either one or both, the whole person shook up and down in the manner I have mentioned, and that when sitting still he had scarcely power to move his legs; that he usually felt cold and benumbed, and frequently trembled; that his head ached, and he suffered from giddiness and dimness of sight, and uneasiness in the *præcordia*; that he often sighed deeply, and at one time was unable to retain his *fæces* or urine. Much of this account might be true or not true, and could not be verified, but depended entirely on his own statement. All that I could learn from observation was, that whenever he attempted to stand he raised himself upon his toes, his body went up and down till he was obliged to sit, and then his feet beat rapidly upon the ground for a few moments. But although I did witness these motions, I had no proof that they were involuntary. I never saw a case of this kind before, but the forms which convulsive diseases assume are so very various, that I did not think it right to say decidedly that the man was an impostor. A complaint of the kind may be possible, although so rare as never to have been read of or seen by me. Of course I began to treat it as a real convulsive disease, intending to make my observations as I proceeded. I accordingly ordered him half an ounce of the subcarbonate of iron to be taken every six hours; the cold shower-bath to be used every day, and electricity to the loins and lower extremities every day also. He very soon, however, began to behave like an impostor. For first of all he complained that he was so very weak that he could not live without having some porter; so I gratified him and allowed him a pint a day. Soon after he said that the shower-bath made him ill for the rest of the day, and he particularly wished it to be discontinued. So this was omitted. He then complained that the electricity, which was given in shocks, for that is the best mode either of curing the disease or detecting imposition, caused him the most dreadful sufferings, and he wished it not to be used every day. So I directed that he should receive shocks one day and sparks the other. But still I could not please him. He next declared that he could not eat the meat of the hospital; that he did not like boiled meat; and in accordance with his wish, I ordered his meat to be fried. He then said that it was not good fried when it had been boiled first. I knew that the middle of the joints of meat are sufficiently underdone to bear frying or broiling, and had therefore ordered these parts to be broiled for him. He begged instead to have mutton

chops cooked expressly for himself. So mutton chops I allowed him. Yet this would not do, for soon after, he complained that he had no appetite, so I gave him the compound infusion of gentian to create him an appetite for his mutton chops, but even then I could not content him. He wanted to go out for two days, having been in the hospital a fortnight, and I suppose that most men in good health, and eating mutton chops, drinking porter, and taking no exercise, and remaining in the house for a month, would be desirous of going out and taking the indulgences of other people. So this I allowed him also, and he alleged a very plausible reason for the request; he said that he was in receipt of a pension, and that it was necessary he should show himself once in three months to receive it; that he should lose it if any three months expired without his doing so. But as the money was to be received in the city I thought that half a day was quite enough, and so I told him, but he replied that as he could not walk, he should be obliged to go to a friend to borrow half a guinea for a coach, and after that should be obliged to go to another friend of his, a cook who resided at Limehouse, who would have to swear that he was the individual to whom the pension was due. So I allowed him two days for his errand. But even all this did not content him; he was dissatisfied with the people in the ward, and with the sister, who, he said, looked too sharp after him; and he also accused a nurse of having stolen eighteen pence from him, and he behaved altogether so ill, that the steward very properly expelled him. The eighteen pence was afterwards found under his bed.

Now, all these were strong presumptive arguments of imposition; for if the man had really been suffering under a complaint which incapacitated him from moving from one part of the room to another without the help of others, he certainly would have submitted to the inconvenience of the shower-bath, to electricity every day, and would have been contented with the hospital diet, and not have asked first for porter and then for mutton chops, with the clean, healthy, moist tongue which he always had; all this looked very suspicious. I have since understood that he had been in another hospital, where he had given a different account of the duration and origin of his disease, and had been turned out on account of his discontented, troublesome behaviour. After leaving us, I hear he went to another the very same day, where he now is. What is singular, and adds to my suspicion, is, that under the use of the electricity, the carbonate of iron, and the good living, he mended, so that from having at first been thrown into a violent agitation on standing, he could at last, with a little assistance, walk up and down

the ward, merely going gently up and down as he walked. But notwithstanding this improvement, witnessed by me more and more up to last Tuesday, I am informed that at the other hospital he presented himself for admission on the Wednesday, with the same degree of agitation up and down, which he exhibited when he applied for admission here. Now of course as he had been progressively mending from his admission on the 20th of October up to last Tuesday, the 2nd of November, it is not probable that twenty-four hours brought him back again into his old state; but if he was an impostor he obviously would at once again exhibit the complaint in its original severity, and make himself appear as bad as possible, that he might secure his admission. That he pretended to improve was, no doubt, that he might be more and more spared the electric shocks, and he invariably grumbled, and tormented the gentleman who electrified him, the whole time of its administration. Besides, when he first came in, I endeavoured to ascertain whether the agitation was real or not, and I knew that if the motions were voluntary he could not long continue them. Therefore I had him supported between two men, and made to stand. He, of course, moved up and down with the greatest violence, but was soon fatigued and begged leave to sit down. I ordered the men still to support him that the motion might continue. He went on more and more violently. He looked like one tormented by fiends, and his eyes started. He was breathless, and piteously implored me to let him sit down. Now if the motions were voluntary, it plainly would have been impossible for him to continue them long, and he would make such a fuss as this in the hope of being allowed to rest. If they were involuntary, the continued standing might aggravate them to this degree. I adopted the former conclusion, because the beating of the feet on the ground after he had sat down always ceased in a few moments of itself, though his feet still remained on the floor. The motion up and down therefore, if involuntary, would probably have ceased spontaneously after a little while, though he had still continued standing. It was also very suspicious that he should select a motion which might be excited by volition—for any one who chooses could do exactly as he did—and very suspicious that he should select a motion not to continue constantly, or long, but only in a certain position; so that he need not be much troubled with it. The posture too, in which the convulsions came on when standing, was one constantly necessary to a seafaring man, and he was liberated from them the moment he sat down, when for a few moments a different motion, performed by another set of muscles all fresh for action,

took place, and then he became quiet and at his ease like other people. There was, moreover, no relation between the two motions, although there was a good reason for having two kinds of motion if the exertion were voluntary. There is another circumstance that looked suspicious. He was thoroughly electrified the day he came in; I stood by, and shock after shock went through the spine. He was then raised from the chair, and he both stood and walked far better than at first, which was very likely to have arisen from his desire to have no more electricity that morning. I tried him in another way also, on a subsequent day. I asked a gentleman who was near the bed to place the soles of the man's feet against his (the gentleman's) thighs, and stand firm; I then told the man to press his feet against the thighs. He did so, and no convulsive motions followed. Now I should have thought that this pressure and exertion ought to have produced the same effect in a lower degree upon the limbs as when the man stood. Yet it did not. Observe that I do not even now positively pronounce the man to be an impostor, but my suspicions are tenfold what they were when he was admitted, and I have a right to give a medical opinion on the case: that opinion is, that in all probability the whole is a mere fudge. It is also to be remembered that the man has been at sea, and that sailors and soldiers excel all others in tricks of this kind,—they practise them continually, and have brought them to great perfection. On inquiring among my friends I have certainly heard of one case a little like it, where the muscles of the ribs were thrown into violent agitation, and after a time disease of the spine presented itself, corresponding with the muscles affected; therefore the occurrence of such a case is, perhaps, possible. But when all the circumstances now detailed are considered, and when we reflect that he was continually laughing and merry after he had secured his porter and mutton chops, and escaped the bath altogether, and the electric shocks every other day, I think there can be little doubt upon the subject.

[From an extraordinary press of matter, we are compelled to postpone the remainder of this Lecture, until next week.]

THE superior maxillary bone, affected with osteo-sarcoma, was extirpated at the London Hospital on Wednesday last by Mr. SCOTT, one of the assistant surgeons. The operation, we learn, was performed with much coolness and precision. We may find room for the report in our next.

## THE LANCET.

*London, Saturday, Nov. 20, 1830.*

MR. DAVIES GILBERT has resigned the chair of the Royal Society, and the proposed election of another president has thrown the Fellows into a state of very distressing commotion. All sorts of calumnies are freely circulated, and vituperative discussion is the order of the day. These strong evidences of violence and wrangling in the supposed field of science, have terribly alarmed the senile of both sexes, for it is conjectured that the people generally must be upon the point of breaking all the bonds of authority, all the ties of social order, from the circumstance of there being so much resistance offered to royalty by the calm and profound philosophers who constitute the Royal Society. There is no just cause for apprehension; there will be no improper resistance offered to royalty. The fellows have long since ceased to be philosophers, and science will not be degraded or retarded in its progress by any president whom such a community of Fellows may think proper to select. The Society has not left sufficient of character to confer honour upon any one, and it has sunk so low in the estimation of all well-informed men, that it has ceased to be mischievous. The body corporate must be purged of a very large proportion of the gross and incongruous materials by which its constitution is oppressed, before it will regain any portion of that elastic vigour which, even in its infancy, forced the reputation of the Society into every civilized quarter of the globe. The Royal Society has evidently long been the arena for jobbing and favouritism, as many who have been elected "fellows," have not the literary qualifications of six-form boys. It may be useful probably, on a future occasion, to analyse the pretensions of a few of them in the pages of this Journal.

THE gentlemen who advocated the rebuilding of Westminster Hospital at Charing Cross have yielded to the voice of the governors so strongly expressed against the measure at the late meeting. Although a ballot was demanded, the "removal" party had the good sense not to attend, and to ninety-six votes for rebuilding the hospital upon its own freehold, there was only one for erecting it at Charing Cross. We rejoice that an affair which at one time had produced no very friendly feeling amongst a number of gentlemen who were all equally anxious for the welfare and continued utility of the institution, should have terminated so amicably. The withdrawal of the "removal" party from further opposition, tends satisfactorily to show that their conduct has not been influenced by sinister motives.

A highly respectable and intelligent correspondent, who has strenuously advocated the Charing Cross side of the question, judiciously asks,

"As the matter is decided *quoad* Charing Cross, what is now to be done? I for one protest against further agitation of the removal. There is no site other than our own freehold, to which the only substantial objection that existed to the site of Charing Cross does not apply. A new site, wherever obtained, must be *paid for*; besides, we are not in favour with the Woods and Forests; and with what reception is another mendicant deputation for a site near the Abbey, or attached to St. James's Park, likely to meet? Is there now more union and energy to be expected on our part—more than former liberality to give—or even more expedition to answer on the part of the Treasury, or of the amiable Board of Commissioners of Woods and Forests and Land Revenues? Time presses. Your powerful pen, Mr. Editor, greatly contributed to our late unfortunate and most unwise determination. I call on you, then, to do what you can towards repressing the spirit of 'agitation'; fostering that of unanimity, and infusing into our councils that business-like activity and disinterested zeal of which we shall hereafter stand so much in need, and without which it would be idle indeed to hope for prosperity under so many disadvantages. But, above all, I call on those governors, in conformity with whose wishes

the removal plan has been abandoned, to exert themselves. At their hands (for whose pleasure the interests of the hospital have, as I conceive, been compromised) the charity may reasonably look for indemnification; theirs will be the reproach, if, as has been predicted, the charity should continue to languish. Let them then make evident their philanthropy by extraordinary exertion, and I venture to affirm that, on the part of the removal party, they will find no lack of zealous co-operatives.—C. M. R. S."

A REPORT of the most prominent of the facts elicited in the evidence given at the inquest held upon the body of Mrs. LLOYD, will be found at page 265. It is impossible to feel pity for the sufferings of any silly creatures who may have placed themselves under Mr. LONG, after the signal exposure of his brutality and ignorance at the inquest on Miss CASHIN. They deserve none; at least they are not beings for whom intelligent people will feel the slightest compassion. They are not unworthy of their fate; but for the reckless, brutal scoundrel, who has thus made a traffic in human life, in human blood, there is no language sufficiently strong to exhibit even the slightest traces of his villany. If possible, the case of Mrs. LLOYD is worse than that of Miss CASHIN; but, strange to say, killing, even if avowedly executed with a view to plunder, is not murder in the eye of the law. Therefore, although LONG has been proved to have killed a second time, yet he has not committed murder, and, therefore, having killed Miss CASHIN and Mrs. LLOYD, he has only, so far, been found guilty of manslaughter. Hence the FELON stands in no dread of the halter; but should he again be found guilty of manslaughter at the Old Bailey, that Judge, even if it be LONG PARK himself, who may pass upon the wretch a sentence short of transportation for life, would assuredly deserve to be "rubbed out" of existence by the atrocious quack's murderous liniment. A fine of two hundred and fifty pounds! This sentence would almost

justify the impeachment of the judge. Where are *now* the quack's titled friends? Besotted boobies!

CALIGULA, when placed in comparison with the framers of the acts and charters, which are to be found in the statute-books relating to the medical profession, was a merciful and considerate law-giver. It were better to live in the most blind ignorance of the penalties to which we are hourly subjected, than to be compelled, for our protection, to enter upon a comprehensive study of the existing numberless medical laws. In the work of Mr. WILLCOCK alone, there is ample evidence to convince the most prejudiced supporter of ancient institutions that neither the popularity, the respectability, nor the utility, of our profession, can advance one step from its present position, if there be not a thorough, a radical reform, in the system of its government. Each branch of the profession has sought for monopoly, and each, in too many instances, has been successful in obtaining it. The interests of the public, and the cultivation of the science of medicine, have not formed items in the petitions for corrupt corporate charters and fraudulent acts of Parliament. Each corporation, keeping a steady eye upon its own individual aggrandisement, has generally succeeded in obtaining an instrument, the movements of which have been invariably wielded to the injury of their contemporaries. Hence the innumerable contradictions to be found in the various medical statutes; so innumerable, that the study of medical law is a species of torture from which the mind would be gladly excused, were it not still more painful, still more perplexing, to continue under the degrading tyranny of unprincipled bands of avaricious and relentless monopolists. Mr. WILLCOCK has laboured hard to bring within a small compass the whole of "the laws relating to the medical profession." In this endeavour

he has been tolerably successful, but the opinions which Mr. WILLCOCK has founded upon the various documents which he has collected, indicate, pretty clearly, the incongruous and dissimilar nature of the materials which he has brought together. They were too much for his powers of digestion, and many other barristers have proved equally dyspeptic under far less embarrassing circumstances. In his second chapter, on the "present orders of the medical profession," Mr. WILLCOCK informs us, that,—

"The law recognises only three orders of the medical profession—physicians, surgeons, and apothecaries. Chemists and druggists also are noticed as persons who may make and vend medicines; and it may be difficult to show that they may not compound them according to the prescriptions of a physician, or the orders of an apothecary; but they cannot, in any case, prescribe physic of their own authority." "The first class of medical practitioners in rank and legal pre-eminence is that of the physicians. They are, by statute, Henry VIII., allowed to practise physic in all its branches, among which surgery is enumerated. The law, therefore, permits them both to prescribe and compound their medicines, and as well to perform as to superintend operations in surgery. These privileges are also reserved to them by the statutes and charters relating to the surgeons and the apothecaries."

When a barrister of eminence writes thus, few persons, we should imagine, will have the temerity to contend that medical law does not stand in need of revision. The errors in the passages here quoted, are not less numerous than the sentences themselves. Mr. WILLCOCK thinks "it may be difficult to show that chemists and druggists may *not* compound the prescriptions of a physician," and, in good sooth, we should think so too, considering that in the twenty-eighth clause of the 55th Geo. III., it is expressly laid down that,—

"All persons using or exercising the trade of chemist or druggist, shall use, or carry on

the said trade or business in such manner, and as fully and amply, to all intents and purposes, as the said trade or business was used, exercised, or carried on, by chemists and druggists before the passing of this act, and that nothing in this act contained shall extend, or be construed to extend, to prejudice, or in any way to affect, the trade or business of a chemist and druggist, in the buying, *preparing, compounding, dispensing*, and vending drugs, medicines," &c. &c.

Here it is clearly enough stipulated that the Apothecaries' Act of 1815 was not in any way to affect the trade of chemists and druggists. Their privileges were to be left altogether untouched; and as *compounding* the prescriptions of physicians and surgeons had, for a long series of years, formed a very important portion of their business, it would be "difficult," indeed, to show that they may not *now* compound the prescriptions of physicians. "But," says Mr. WILLCOCK, in the concluding portion of the passage already quoted, "they cannot, in any case, prescribe physic of their own authority."—Why not? This is another very obvious error, as is clearly shown by the clause which we have just quoted from the Apothecaries' Act. Chemists not only dispensed the prescriptions of physicians and surgeons before the year 1815, but they prescribed in their shops previous to that year; and, in numberless instances, they *visited* patients. Thus, in fact, having invaded the territories of the apothecaries in precisely the same manner as apothecaries had previously obtruded on the provinces of the physicians. Therefore it is quite clear that all the privileges and immunities of the chemists and druggists remain unbridged by the Apothecaries' Act of 1815. Chemists can compound, prescribe, and follow every avocation connected with their trade, which they pursued before the 55th of Geo. III. received the sanction of the legislature. For these advantages they are indebted to the Fellows of the College of Physicians

who, when the Apothecaries' Bill was in Parliament, strenuously exerted themselves on the behalf of persons with whom there had been long existing a co-partnership in the per-centage trade. It would have been an unjust restriction, probably, to deprive the chemist of the right of compounding the medicines directed by legalised prescribers; but it certainly is impolitic, unjust, and dangerous, to permit men, who have not enjoyed the benefits of a medical education, to exercise the prerogatives which, in all other instances, are alone awarded to the qualified practitioner.

Mr. WILLCOCK next states that the law permits physicians to prescribe and *compound* their medicines. This is another very palpable error; for, strange as it may appear, the provisions of the Apothecaries' Act unequivocally subject any physician to the specified penalties for dispensing either his own prescriptions or the prescriptions of any other physician, if he be not a licentiate of the Apothecaries' Company. In a word, neither a fellow of the London College of Physicians nor a graduate of the University of Edinburgh can follow the business of an apothecary, avowedly as an apothecary, in this town, without rendering himself amenable to the penalties of the Apothecaries' Act, which distinctly declares, that it is the duty of the apothecary to dispense, with exactness, the prescriptions of legally-authorised physicians. This is particularly mentioned as the trade, or profession, of the apothecary; and that, in order that a man should carry on this trade legally, he is required to serve an apprenticeship of five years to an apothecary, and, subsequently, to obtain a certificate of qualification from the corporation specified in the Act. Consequently, there is the gross absurdity of conceding to physicians and surgeons the privilege of prescribing for the cure, or relief, of the most important and complicated of diseases, and, at the same time, subjecting each to a penalty of twenty

pounds, for mixing and administering the most simple pill or draught. Mr. WILLCOCK says, that these privileges (which they do not possess), were reserved to them by the statutes and charters relating to the surgeons and apothecaries. No statement can be more erroneous; for many privileges of surgeons were taken from the physicians by the last charter of Geo. III. The decision of the House of Lords, on the appeal case of ROSE and SEARLE, conferred upon apothecaries the privilege of prescribing, as well as of compounding; and the Apothecaries' Act of 1815, not only confirmed that privilege, but excluded the physician from any such advantage. The act and the decisions of the judges agree in withholding from physicians and surgeons the right of exercising the trade or profession of the apothecary,—whether wisely or not, will be seen hereafter.

Such is the confusion that prevails on this subject, that the errors we have noticed are all to be found in one page, and are embraced within a few lines of the work of Mr. WILLCOCK, a barrister who has zealously laboured to furnish the profession with a perspicuous view of the tendencies and peculiarities of medico-legal enactments.

---

BETHLEM HOSPITAL.—*Minutes of Evidence taken by the Committee appointed to inquire into the Charges preferred against Dr. WRIGHT, the Apothecary and Superintendent, and his Answer. Ordered by a Court of Governors, held Sept. 28, 1830.*—London. 1830.

We have this moment risen from the perusal of this "evidence," and the proofs of black malignity and foul conspiracy against Dr. Wright are so manifest in every page, that we are almost choked with indignation. Merciful powers! Is a man of character, talent, and spotless integrity, the father of a numerous family, the husband of an amiable and affectionate wife, to have his

character blasted in a moment by the testimony of a pack of discarded servants? Testimony, too, that has received the most unequivocal contradiction from numerous gentlemen of high and unsullied character? From the tone of the questions propounded by the committee, it may fairly be inferred, that it was not a committee that met to inquire, but a committee that assembled with a fixed determination to condemn; for their interrogatories, almost without exception, are *leading* questions, all aiming at the same object,—to elicit proof of the *guilt* of the accused. Fairness and impartiality there are none. Can the noble and honourable governors of an institution, the existence of which reflects such honour on the judgment and humanity of the country, sanction proceedings so infamous, or conspiracy so diabolical? We implore them to examine the evidence with the most deliberate attention; and after having done so, we feel assured that, on the day of election, they will rush forward and show their anxiety to assuage the pangs of wounded honour, by reinstating Dr. Wright in the office from which he has been so flagrantly removed.

---

WESTMINSTER MEDICAL SOCIETY,

November 6, 1830.

---

Dr. STEWART in the Chair.

---

ELONGATION OF THE UVULA.

AFTER Dr. Stewart had returned thanks for his late election as one of the presidents of the Society, Mr. Douchez read a short but interesting paper on the chronic elongations of the uvula, which are occasionally known to follow syphilis, protracted fevers, and the use of mercury, and also to proceed from over exertion of the vocal organs in professional singers. By this elongation, the author observed that very great irritation, cough, and suffering, were produced. He cursorily alluded to the ordinary reme-

dies used in such cases, and recommended the total excision of the uvula as the most efficacious mode of relief. He had operated in three cases with the utmost success, and he particularised the instance of a manservant, in whom, after the usual remedies had been ineffectually tried, he laid hold of the uvula with Assalini's forceps, and effected its removal with little more than a momentary irritation. Similar cases, he continued, were detailed in *THE LANCET* about two years since, and in the *Medico-Chirurgical Review*. He also alluded to some cases related by Baron Larrey; but from this distinguished author he differed slightly, as he (Mr. Douchez) recommended the total extirpation of the part, while Baron Larrey only advised the removal of the superfluous portion. He was not aware of any serious ill consequence which the operation thus conducted could induce. In one case, however, he was informed by a friend, that the articulation of certain consonants was rendered imperfect.

Dr. GRANVILLE complimented the author on the practical value of his brief communication; he alluded further to the very distressing nature of the affection, and thought that the proposed operation might often be very advantageously and safely performed, so safely indeed, that no physician, surgeon, or general practitioner, need hesitate about carrying it into execution. As to the ordinary remedies, he had known the several vegetable astringents tried over and over again without success; the Cayenne pepper was of use in some cases, but the remedy on which he most relied, was the application of lunar caustic in solution, the strength of which should be varied according to the state of relaxation of the uvula, and also according to the degree of nervous irritation in the system. This last point was of especial consequence in females, yet this remedy too he had known to be ineffectual. There was another, and he believed a very useful one, namely, a powder composed of equal parts of muriate of ammonia and nitrate of potash, with one-fourth of Cayenne pepper. This produced great instant irritation, and was followed by copious salivation, and the expectoration of the thick mucus, which, in these cases, generally clogs the internal fauces. The powder should be rubbed on with a camel-hair brush twice or three times a day.

Mr. BACOT was of opinion that the operation of excision of the uvula, though exceedingly simple, was yet attended with the most striking benefit. He thought, indeed, there was no operation whatever conferred more signal relief on the patient. He had performed it twice or three times in cases of chronic cough, which could not be attributed to any other cause but uvular

elongation, and in these cases it was entirely successful. He did not think it necessary to remove the whole of the part; the uvula might be of some use, and he should prefer the mere excision of the elongated portion. In the inflamed condition of the parts, he had known the use of a strong solution of the acetate of lead to be exceedingly beneficial.

To a question from the chairman whether the flow of blood was considerable after the operation in his cases, Mr. Douchez replied that it did not exceed two or three drachms. Mr. BACOT thought the hæmorrhage too trifling to interfere with the operation in the slightest degree. Mr. CHINNOCK said, he knew of one case in which the hæmorrhage was copious, but was readily arrested by the use of the lunar caustic. He thought with Baron Larrey and Mr. BACOT, that the elongated part alone, and not the entire uvula, should be removed. Mr. Douchez rejoined, that though he had spoken of the total excision, yet that in his own practice he had removed the whole uvula but once.

The CHAIRMAN having observed that he had heard that professional singers were in the habit of employing a preparation into which the sulphuret of potash entered, Dr. O'SHAUGHNESSY inquired if the natural tone of voice was altered in any degree, in the cases in which the operation was performed. Mr. Douchez and Mr. BACOT in reply, said that they did not recollect any particular alteration. In one of the cases the former gentleman noticed, the articulation, as he had already stated, was affected in a slight degree.

Dr. O'SHAUGHNESSY was induced to ask the question, in consequence of the peculiar opinions on the nature of the *modulation* of the voice (distinguished from *articulation*) which had been recently advanced by M. Bennati. This gentleman is at the same time an eminent physiologist and a distinguished singer, and during a professional tour the summer before last, demonstrated the influence which the soft palate and uvula possess over the modulation of sounds, at one of the entertainments of the College of Physicians at Edinburgh. According to this gentleman, the soft palate and uvula contracted in proportional degrees to the ascent of the several musical notes, and this he demonstrated by opening his mouth widely and running up the gamut, with a light held before his throat. An account of M. Bennati's opinions was to be seen in the *Annali Universali* for June (as he believed), and in the *Bulletin des Sciences Medicales* for May, 1830. He (Dr. O'S.) was not present on the occasion alluded to, but his attention was first directed to the subject by Dr. Duncan, the very eminent professor of materia medica in the Univer-

sity of Edinburgh; Dr. Duncan was of opinion that M. Bennati had gone far to prove the influence of the soft palate and uvula over the modulation of voice, and he (Dr. O'S.) therefore thought, that the circumstance was worthy of some consideration in the practical opinion which the Society might form of Mr. Douchez's communication, especially since professional singers constituted a large portion of the patients afflicted with these elongations.

Dr. GRANVILLE said, that in the pursuit of his multifarious avocations, he had been eight years physician to the Opera company; as such he had of course been frequently called on to examine the internal fauces of the most celebrated singers, when certificates of incompetency to perform were required. It struck him at this moment, that his observation of the conformation of the uvula in these individuals, went to confirm the opinions to which the preceding speaker had alluded. In the deep bass voices he distinctly remembered, that the uvula was thick and carneous, while, on the contrary, in the light, silvery soprano singers, such as Madame Ronzi de Begnis, it was extremely thin and sharp at its loose extremity; in this lady in particular, it formed the apex of an isosceles triangle, not more than two-tenths of an inch in magnitude: he had, indeed, noticed this in all contr'alto voices. With respect to the employment of the sulphuret of potash, he thought it was borne out by a very strong analogy, he alluded to the effects it was known to possess in croup, of converting the stridulous voice into a deep full tone. It was the remedy for the recommendation of which Napoleon Buonaparte had awarded a prize of 1000 napoleons during the epidemic croup which raged in Paris in 1812.

The discussion here was suspended, and Dr. Granville proposed the secondary effects of colchicum for consideration. It was not, however, at once proceeded with, and in the interval

Mr. CHINNOCK stated, that in the treatment of elongated uvula, he believed the lunar caustic to be a most important remedy. That evening there was a performer singing before the King at the Opera House, who had immediately before the performance gargled his throat with a solution of the nitrate of silver. His affection, however, was that of mere relaxation.

Mr. BACOR understood that a still simpler remedy was resorted to under parallel circumstances by the pupils of the Royal Academy, namely, gin and water (*a laugh*); he was quite serious; it was of course only as a medicinal local application.

Dr. A. THOMSON observed, that in these cases of relaxation, it was probable there was some inflammation of the cellular tissue

beneath the mucous membrane of the velum and uvula. If this were the case, he could not comprehend how the stimulant treatment alluded to could operate in the removal of the affection. The primary effect of the local stimulus would certainly be to inject a still greater quantity of blood into the inflamed parts, and thus increase the tumefaction.

#### SECONDARY EFFECTS OF COLCHICUM.

Dr. GRANVILLE again called the attention of the Society to the secondary effects of colchicum. He wished for information as to the effects of this remedy, observed by the members in their experience. He thought the subject was one of very great importance. Very recently the sudden death of an eminent barrister was ascribed, with what truth he (Dr. Granville) could not say, to the accumulated effects of this powerful medicine.

Dr. A. THOMSON said, that the effects of colchicum, when it proved fatal, were very extraordinary. In one case of poisoning by it, which had fallen under his observation, a most singular hæmorrhagic condition was induced: every surface of the body, except the skin, poured out quantities of blood; from the living membrane of the lungs the quantity was indeed so great that it might be imagined an artery had given way. This peculiar effect was found in every mucous surface of the body, even including the bladder. Another extraordinary effect was a peculiar laxity of the cellular tissue, and a loss of its adhesive powers. The vitality of this tissue seemed, indeed, to have been entirely destroyed.

Dr. GRANVILLE mentioned the cases of two young gentlemen, who were afflicted with hereditary gout, and who had been taking colchicum for a long period. One of these became epileptic, and died; and the second died of apoplexy. Wilson's preparation was the one used in these cases. He had known, also of the case of a nobleman, in whom the chalky arthritic deposition had taken place to a great extent, but all which deposition disappeared under the use of colchicum. The patient, however, died; and, on examination, extensive arterial ossification was found, especially on the right side. He had never seen such a case as that mentioned by the last speaker, and therefore could offer no opinion as to the peculiar appearances that gentleman described. On the whole, Dr. Granville thought the secondary effects of this remedy were often of a dangerous character, and that its administration should be conducted with great caution.

Dr. A. THOMSON had not noticed any vascular injection in the mucous surfaces. He believed that, in these cases, death took

place from what Dr. Abercrombie termed simple apoplexy. The heart could not dilate the arteries of the head; the veins consequently could not be emptied. The equilibrium of the circulation being thus disturbed, the nervous energy was diminished, and could not be again renewed. In reply to a question from a member, Dr. Thomson stated that the preparation taken in the fatal case he mentioned, was the wine of the seeds. He believed that the remedy did occasionally accumulate, and then produced a very great collapse.

The CHAIRMAN begged to remind the society that it was not as a poison, but as a remedy, that colchicum was to be considered.

Dr. THOMSON replied, that he wished to show the maximum effect, in order to apply that to the elucidation of the ordinary action of the remedy. He then entered into a minute detail of the symptoms he noticed in the case he had already mentioned.

Several gentlemen stated the results of their practice with colchicum, in short addresses, for which we cannot afford space. Messrs. Chinnock, Stoddart, and Bacot, had used it extensively, and had never met with any bad result. Dr. A. Thomson had occasionally observed it induce green stools in acute rheumatism, a fact which he considered rather as corroborative of the hypothesis that this disease was connected with hepatic disorder. The Chairman also had used colchicum with the greatest success, and had noticed no secondary ill effects. He might add, that he had been lately induced to try it in a case of obstinate lepra, which had resisted all other remedies; but he gave the colchicum combined with magnesia, and whether it was the effect of the medicine or not he would not say, but the patient had experienced very great and speedy benefit.

On the whole, the general opinion of the Society was highly in favour of the value of colchicum, and no material additional testimony was given of any dangerous secondary effects resulting from its medicinal employment.

## WESTMINSTER HOSPITAL.

### PNEUMONIA COMBINED WITH ANASARCA.— PREMATURE LABOUR INDUCED.

FRANCES LEADER, ætat. 18, admitted 14th of October with pneumonia and anasarca; countenance anxious; pulse laborious, about 120; respiration difficult and hurried; acute pain under the left breast; skin hot and dry, except the forehead, which is covered with perspiration. *V. S. ad 3xiv.*

*Hirudines x, parti et postea emplast. lyttæ; Bolus ex calomel. et antim. tartarizat., gr. x, statim;*

*Hæust. pürgans salin. 2dis horis donec solut. sit alvus.*

5. Respiration free; pain of side, but not so much increased on inhalation; face tranquil; pulse 112, soft; skin hot; bowels open; lips parched, but tongue moist; has made water well; the swelling has left the legs. The blood drawn last night is buffed and cupped. *V. S. ad 3vj.*

6. Blood taken away yesterday buffed and cupped; breathing more tranquil; pulse hard and undulating; pain of side continues, but in a less degree; bowels open. Has taken a mixture of *sæth. nit. liq. emmen. acet. et mist. camphoræ. V. S. ad 3vj.*

7. Blood extracted buffed and cupped, but not in an equal degree with the last; has still some pain of side; tongue white; respiration continues a little hurried; face tranquil; pulse 120, quick; respiration *puerile* on the left side, but full on the right. *C. C. ad 3viii.*

*Rk Calomel., gr. i;*

*Antim., gr. i, ft. pil. ter die.*

8. Was relieved by the cupping; scarcely any pain of side this morning; respiration tranquil; tongue clean; bowels open; pulse 106, sthenic, but of moderate calibre.

9. A little pain of side remaining; has slept well all night; breathing easy; bowels open freely; cough producing slight pain in the affected part; pulse salient, strong, 108. *Addæ mist. antim. tart., gr. iv.*

10. Last night an accession of pain of side and dyspnoea; twenty leeches to be applied immediately.

Feels better this morning; breathing accelerated and laborious; pulse small and sharp, about 90; bowels open; skin hot, but moist. *V. S. ad 3vj.*

11. Blood buffed and cupped; pain diminished; pulse quick, of moderate calibre; bowels open. *Hirudines, x, lateri.*

12. Considerably better this morning; pulse reduced; respiration tranquil; bowels open.

13. Mouth slightly sore, arising from the calomel; very slight pain of side; pulse sthenic, 96; face calm; bowels open.

14. Improving; mouth sore; pulse 104 at par; pain entirely gone.

15. The respiratory murmur has become natural on both sides; convalescing.

17. From the darkness of the areolæ, it was suspected on admission that the patient was pregnant, and sure enough labour came on last evening about three o'clock, and she was safely delivered, in about an hour, of a fœtus about five months old.

Ten P.M. She is exceedingly well, cool, and free from fever.

17. Very tranquil; pulse 108, sharp; free from pain.

19. Convalescing; no pain in any part; tongue slightly furred; bowels open; pulse 104, strong; skin moist and warm; a slight secretion of milk.

20. Tongue little furred; bowels open; breathing free; no pain; skin moist and warm; pulse 102, pretty strong.

22. Has got out of bed to-day; appetite improving; convalescent.

## PERITONITIS.

Sarah Canfield, ætat. 15, living with her mother, but generally employed from home as a servant, admitted with inflammatory fever, Wednesday, 13th of October. Pulse 120; respiration accelerated; headach and pain all over the body; pain of chest.

*V.S. ad 3viij;*

*Mist. diaphoretica;*

*Bolus calomel. et antim.*

The attack came on with alternate heats and chills about four days ago, with general pain; she was bled, but without alleviation; catamenia regular.

14. Blood drawn yesterday slightly buffed; crassament consistent, small quantity of serum; pain has removed to right side; bowels open; pulse 108, resilient; tongue furred; no headach; the mixture induced slight nausea. *C. C. lateri dextro ad 3viij.*

15. Cupping relieved the pain of right side, but she now complains of great pain in the chest and left side; respiration rapid, irregular, about 50.

16. Thinks herself much better this morning; expression natural; no pain; tenderness of abdomen scarcely evident; bowels open; tongue still furred; skin cool; slept well in the night; mustard plaster to the abdomen, which afforded considerable relief yesterday; pulse 108, in considerable force.

18. Tenderness of abdomen has disappeared; tongue less furred; bowels open; pulse 88, natural.

19. Last night there was a feverish exacerbation; pulse was 120, powerful; skin hot and dry, and hysterical symptoms were present.

This morning says she is better; slight tenderness of abdomen; bowels open; tongue much cleaner than last night, though still slightly furred; respiration 36; pulse 102, strong; skin warm and moist. *Rep. med.*

Ten P.M. Slight return of pain in the abdomen, for which a sinapism was ordered.

20. The sinapism afforded present relief.

21. Feels much more comfortable this morning; no tenderness of abdomen. On sitting up, feels a sharp pain in the left hypochondrium; countenance placid; tongue

furred; bowels open twice since yesterday morning's visit; pulse 96, natural.

*Mist. effervescent.*

22. Bowels confined these two days; lips a little dry; pulse small, 88.

23. Sits up, and is pronounced convalescent.

## HOPITAL ST. LOUIS.

## DISLOCATION OF THE FOOT.—EXTIRPATION OF THE ASTRAGALUS.

A. ROCHER, ætat. 46, of a robust constitution, was admitted on the 6th of February last, in the following state:—The sole of the right foot was turned inwards, and its upper surface outwards, the latter was fixed to the lower end of the fibula, the ligaments of which were lacerated, so as to admit of a separation of the tibia and fibula to the extent of almost two inches; at the lower portion of the fibula, there was a depression which, at first sight, was supposed to be caused by fracture, but proved to be only a curvature; there was also a wound about an inch in length, through which the fibula was protruded; the patient had lost much blood, and there was still some hæmorrhage, which was, however, arrested after about half an hour. Before the tibia and fibula there was a large tumour, which was immediately recognised to be the astragalus thrown out of its natural position, and resting on the posterior portion of the upper surface of the cuboid bone. The medical attendants immediately tried to reduce the bone, but unsuccessfully; and it was ultimately found necessary to desist from the attempt, and merely to apply a bandage, in order to keep the bone as much as possible in its natural position; a poultice was also placed over it, and the patient largely bled. On the following morning, M. Richerand also tried to reduce the dislocation, as did M. Cloquet, but their endeavours were as ineffectual as those made on the day before. The extirpation of the astragalus was accordingly decided on, and performed in the following manner:—an incision of the form of a T was made over the astragalus through the skin, and the flaps dissected from underneath; the sponerosis was then divided, and the tendons of the peroneus, extensor communis and extensor hallucis proprius being kept towards the inside; the bone was completely laid bare, and without any difficulty detached from its connexions. After the removal of the bone, the foot was easily brought into its natural position, and kept in it by a simple bandage. Bleeding to sixteen ounces was now ordered, and repeated to a less extent towards the

evening, as the fever was rather high. The night was pretty tranquil. On the morning the pulse had again so much risen as to induce M. Richerand to order a third, and towards the evening a fourth bleeding. From this time all symptoms of irritation subsided; suppuration of a healthy kind took place, and every thing seemed to indicate a favourable termination. On the 15th, however, an oedematous swelling at the inner angle had begun to develop itself, which gradually became larger, and after a few days exhibited fluctuation; a large quantity of healthy pus was evacuated, and the abscess was found to extend as high as two inches above the angle. Suppuration continued to be moderate and of healthy nature, and the wounds had a good appearance, when, on the 28th, without any obvious cause, erysipelas came on and spread rapidly over the whole leg; the skin, over the vena saphena, was of a bright-red and extremely sensible, and all the symptoms indicated the presence of very intense phlebitis; the fever was not very high. Eighty leeches were applied, the whole leg was covered with fomentations of inf. althææ, and the patient kept to spare diet. This treatment was followed by immediate relief, and after six days all dangerous symptoms had disappeared. However, from the middle of March, up to which time the patient seemed to be gradually improving, the disease took a new aspect; the patient was feverish, lost his appetite, vomited occasionally, and was much harassed by frequent attacks of cough; the epigastrium was very tender, the bowels were loose, &c.; suppuration diminished, though the wounds did not make any progress towards healing. These symptoms were, however, also happily subdued by means of opiate glysters, effrvescing draughts, and a blister to the epigastrium, and all seemed to go on favourably, when he unfortunately received the news of the death of his son; this accident immediately brought on a relapse, which however was also subdued; the wounds had merely cicatrised, and there appeared to be no obstacle to the patient's speedy recovery, when his wife applied for his removal from the hospital, which having been granted, in spite of the danger which evidently attended it, the patient was reported to have died eight days after his discharge from the hospital.—*Journ. Hebdomad.*

feet in height; they were taken up insensible, and in both the vertebral column seemed to have been fractured. Dr. Graef, of Trarbach, who reports the case, found them with violent pain in the back; in the elder, several of the spinal processes of the lower dorsal vertebrae were moveable and crepitous; the stools passed involuntarily, the urine was completely suppressed, sensation and movement of the parts below the lesion were suspended, and the lower extremities were quite cold; in the younger brother, the lesion affected the lumbar vertebrae, the spinal processes of which projected considerably; the symptoms were similar, though less in degree than in the elder brother. The treatment consisted in cautious extension on a table, the patient lying on the abdomen; reduction of the displaced parts by pressure into their natural position, general and local bloodletting, the application of ice for a week, posture on the abdomen, aperient and nitrous mixtures, and when the inflammatory action had subsided, in the use of arnica. In the elder brother, the paralytic state of the bladder was the most obstinate symptom, but was also eventually cured by the repeated employment of leeches and cold applications to the perinæum and the region of the bladder; the use of the lower extremities was also gradually restored, and on the 39th day after the accident, the elder brother, who had suffered most, was able to sit up and to move his legs pretty well; the younger could slowly walk. In both a slight protrusion at the place of the lesion was still perceptible. After four months, both brothers were nearly well; the younger had completely recovered the use of his limbs, but suffered much towards the end of his recovery, and even afterwards, from lancing pains in his legs. The elder also recovered, but much more slowly; and it was only through the continued use of aromatic remedies and baths, of nux vomica, and the croton oil, that the paralysis of the rectum, bladder, and lower extremities, was at length removed. Towards the end of his recovery his wife died, he married again and had children by his second wife. In January, 1829, he fell with a weight on his back, and dislocated his shoulder, and was also completely cured from this accident. In the spring of 1829 both brothers were perfectly well, and as capable of work as before.

#### RECOVERY FROM EXTENSIVE LESION OF THE SPINAL COLUMN.

In the *Kritische Rep.* the following case is related:—Two brothers, both of very vigorous constitution, fell from a scaffold thirty

#### LARGE LUMBAR ABSCESS IN A CHILD FIFTEEN MONTHS OLD.

The "Eyr, Medicinske Tidsskrift, 1829," contains the following description of an enormous abscess in a boy of 15 months old. The abscess extended from the first lumbar vertebra down to the right ilio-sacral sym-

physis; the psoas and iliacus muscles were entirely destroyed, with the exception of their common tendon, which had, however, no point of insertion, as the little trochanter was also destroyed by caries. The centre of the abscess was at the right ilio-sacral symphysis, and from this part there extended three large sinuses, one ascending between the peritonæum and the transversalis muscle up to the navel; another which descended anteriorly along and under the common tendon of the psoas and iliacus in front of the hip-joint; and a third, which was the largest, down into the small pelvis, at the exit of which it traversed the great ischiatic notch, passing under the glutæus maximus anteriorly, so as to communicate with the second branch. The capsular ligament of the hip-joint was entirely destroyed; the acetabulum carious and flattened, and no trace of the cartilaginous surface left; the head of the thigh-bone was also destroyed, and the rest of the femur enlarged and carious. The disease had apparently been only of eight weeks standing.

### TAPPING IN HYDROCEPHALUS.

DR. CONQUEST has again succeeded in tapping for *water in the head*. It will be recollected that in one of the former numbers of *THE LANCET* the particulars of his *first* case were detailed; and it is highly gratifying to learn that the little girl continues in perfect health, without a vestige of her former deplorable disease.

The *second* case is also a girl, and was exhibited to the pupils at St. Bartholomew's Hospital last week, and appeared to be an intelligent infant, and free from the ordinary characteristic symptoms of hydrocephalus, although before the operation she had fits every day, and was altogether a very pitiable object. The water had been withdrawn by two operations. Twelve ounces were taken away at the first operation, and eighteen at the second. In this case the trocar was introduced into the lateral ventricle by the coronal suture on the left side of the head, just below the anterior fontanelle.

DR. CONQUEST has a *third* case under his care, for the relief of which he has already operated four times, and proposes very shortly to perforate the head a fifth time. The total quantity of fluid hitherto taken away is about forty ounces. The operation was performed twice before his pupils at the hospital, and although he does not seem to anticipate a cure in this case, yet the relief afforded has been very decided, and it must be extremely consolatory and encouraging thus to have accumulating evidence that this

direful malady admits of cure in many, and of relief in most instances.

Dr. Conquest, after his lecture at St. Bartholomew's on Tuesday evening, had the child, about seven months old, brought into the theatre, whose head he had punctured on the above occasions, in consequence of hydrocephalus. The head appeared enormously swollen, its veins very much distended, the bones separated to a great extent, and the skin covering it had a shining appearance. A fine trocar was introduced through the coronal suture, on the left side, just above the squamous portion of the temporal bone, and carried into the lateral ventricle; upon withdrawing it, about twenty ounces of a transparent fluid were evacuated. As the fluid escaped, pressure was made on the head in every direction, by means of adhesive plaster. When all the fluid had been evacuated, the wound was closed by a strip of adhesive plaster, and the mother removed the child from the hospital. Dr. Conquest stated that, in his former operations on this child, the fluid that was voided was tinged with blood, and portions of brain were mixed with it.

St. Bartholomew's Hospital,  
November 17th, 1830.

### OPERATION OF TYING THE AORTA.

LETTER FROM MR. JAMES.

To the Editor of *THE LANCET*.

SIR,—Allow me to trouble you with the following observations, which I feel it right to make, in consequence of seeing, in the Review published in "*THE LANCET*," of the case which I transmitted to the Medico-Chirurgical Society, an incorrect statement to the following effect; namely:—"Mr. James resolved upon tying the aorta, notwithstanding the objections of his colleagues, who all saw the hopelessness of the case." Now the fact is, that one of my colleagues, Mr. Barnes, whose opinion I conceive is entitled to much deference, did fully concur with me in opinion that the man should receive the chance, however small, which the operation afforded, if, upon a full explanation of the circumstances to him, he was disposed to take that chance; and I believe, upon this point, I may appeal to any of my colleagues—that the most explicit statements were made, both to the patient and to his friends, on the circumstances of his case; and it was at his own desire, and with his friends' concurrence, that the operation was performed. With respect to the time at which it was done, I

can only say, I was convinced myself that Sir Astley Cooper judged rightly in advising its being performed before matters had proceeded to extremity, as in his own case. The same feelings which actuated him, led me not to abandon a fellow-creature to what I believe was an inevitable death, without an attempt to save him.

I have the honour to be, Sir,  
Your most obedient Servant,  
J. H. JAMES.

Exeter, Nov. 11, 1850.

---

THE PROSECUTOR'S COSTS, IN THE LATE  
TRIAL OF JOHN LONG.

---

*To the Editor of THE LANCET.*

SIR,—I find it stated in one of your recent numbers, that Mr. Wakley has, hitherto, borne the whole expense of conducting the prosecution of the great metropolitan arch-quack, John St. John Long, who was found guilty, by a respectable jury of his countrymen, of having *manslaughtered* (O the goodly fitness of law terms!) a young lady, while in the prime of life and health, and whose punishment has been the subject of no inconsiderable surprise to the higher, and of indignation to the lower, classes of society. Respecting the manner in which Mr. Wakley conducted the original inquiry, which led to that prosecution, there never was but one unanimous feeling of commendation among the numerous members of the profession with whom I have the pleasure of associating. But now that we are informed, that in order to complete his praiseworthy enterprise of exposing unblushing and criminal ignorance, Mr. Wakley has not hesitated to buckle on himself the whole of the pecuniary responsibility,—often very heavy, and always inevitable, which attaches to those who, in this country, claim the protection of the laws, it becomes our duty, as it must be the duty of the public at large, who will reap ultimately the benefit of Mr. Wakley's endeavours, to come forward and relieve him, as the *Medical Gazette* very justly observes, from a burden which it would be disgraceful to suffer him to bear.

It is in accordance with such a feeling that I beg you to offer to the proper quarter the inclosed mite towards defraying the law expenses incurred by Mr. Wakley in procuring the conviction of John St. John Long of his *first* legalized murder.

I remain, Sir, your  
Humble Servant,  
A. B. GRANVILLE.

16, Grafton-street, Berkeley-square, Nov, 13, 1850.

\* \* Received the cheque for 2l. 2s.

ST. BARTHOLOMEW'S HOSPITAL.

*To the Editor of THE LANCET.*

SIR,—The reform which has taken place in the hospitals of this metropolis since the publication of *THE LANCET*, has induced me to lay before you some abuses which at present exist at St. Bartholomew's.

Mr. Earle has on every occasion evinced a great desire to be of service to the pupils, and in no instance more so than by the valuable lectures which he delivers weekly. He has, however, chosen an hour to lecture, during which Mr. Vincent is going round the hospital, and thus those who accompany Mr. Vincent are deprived of Mr. Earle's remarks. I feel assured that it is not intentional, and that it needs only to be mentioned to be remedied.

I may also take this opportunity of exposing the conduct of *certain* *puppies* who make a practice of smoking cigars in the anatomical theatre, previous to Mr. Lawrence's entering to give his surgical lecture. Their exploits, however, are not confined to the anatomical theatres, but extend to the wards of the hospital, infecting their already not too salubrious atmosphere. Some of them may have learned it abroad, but the others have not travelled beyond the precincts of the London pot-houses.

Mr. Lawrence has already given the *puppies* a hint to discontinue the practice, but without effect. If this notice should be also disregarded, I shall take an early opportunity of forwarding their names for insertion in *THE LANCET*, if you think they will not sully its pages; but if so, perhaps an application to Mr. Helps the treasurer, stating names and particulars, may prove equally beneficial. By the insertion of this letter in an early number of your excellent Journal, you will add to the many obligations already conferred on the pupils and patients of this hospital.

A PUPIL.

St. Bartholomew's Hospital,  
November 15th, 1850.

REVIEWS OF NEW WORKS.

---

*To the Editor of THE LANCET.*

SIR,—I cannot too greatly admire the boldness and impartiality with which you review all new medical works; the advantage of your just criticisms is of infinite importance, not only to the profession in general, but to the student in particular.

A few weeks since, "Professor Pattison of the London University," introduced "Fyfe's Anatomy" to the notice of his class, "observing that it was usual to re-

commend some work to the student, and he had much pleasure in offering to their notice a new edition of his friend, Mr. Fyfe's, work which he considered a very cheap and useful book, and bestowed some flattering lucubrations on the style and quality of the plates."

Now, Mr. Editor, Professor Patison must be grossly ignorant of the subject he professes to teach, or wilfully blind to the interest of his pupils, many of whom, but for the timely review of this work in your able Journal, might have been induced to purchase it upon the "ipse dixit" of an *imbecile professor of anatomy*.

I am, Sir, yours respectfully,  
MONTESQUIEU.

London, November 7th, 1830.

## EPILEPSY.

*To the Editor of THE LANCET.*

SIR,—The following is a case of epilepsy, assuming the intermittent form, in which I have successfully employed the sulphate of quinine. Should you think it worthy of insertion in your valuable periodical, its publication would oblige,

Yours sincerely,

P. W. BARRETT.

42, Great Marylebone Street.

The patient (Ellen Sullivan) gave me the following account of her symptoms:—She stated that she was in the habit of carrying heavy loads on her head, that about twelve-months since, she was attacked with fever, and on her recovery became deranged; that she was admitted into the Marylebone Infirmary, whence she was discharged cured; that she was afterward hired as a servant, and that while at prayers one evening was first attacked with these fits; that by the direction of the medical gentleman who attended her, she again applied at the Infirmary, whence, after a short time, she was discharged as incurable. She was then recommended by Mr. Mayo to the Middlesex Hospital, where she was treated as an out-patient. After a short attendance there, she was told, "that if the medicines she then got were of no service, she need not apply again." Under these circumstances, she was recommended to me; her symptoms were as follows:—Severe pain in the head, which had existed for the last year; great thirst; severe pain in the right side, augmented by pressure; liver slightly enlarged; abdomen swelled; bowels costive. Menses had not appeared for the last year; had a fit regularly at four o'clock every day: this was on the 15th of August last. When she first applied to me, I immediately determined on trying the effects of the sul-

phate of quinine. Seeing that there was a regular intermission of twenty-four hours, I therefore ordered her the following mixture:—

15. *R. Sulphatis quininae*, gr. xvj;  
*Infus. valeriana*, 3vj;  
*Mistura camphora*, 3iv;  
*Tinctura valeriana*, 3ss. M. ft.  
mistur. cujus agra sumat. cochlear. quatuor magn. 3tia vel 4ta  
quaque hora.

*R. Ol. ricini*, 3vj;

*V. O.*

*Aqua cinnamomi*, 3iss. M. ft.  
haust. cras mane sumend.

On this day had no return of the fit.

16. Bowels well open; stools dark and fetid; abdomen less swelled; had no return of the fit. Directed her mixture to be continued, with the addition of tinct. sabinæ, 3iij.

17. No return of the fit; bowels costive  
*Repet. haust.; repet. mistur.*

18. Bowels well open; stools more healthy; and had no return of the fit.

19, 20, 21. Pursued the same mode of treatment; much better, and had no return of the fits.

22. Side painful; ordered her ten grains of the blue pill at night, and the above draught on the following morning.

23. Better, still no return of the fit.

*Repet. pil. hyd.*, gr. v, omni nocte;  
*Repet. mistura quinae.*

24 and 25. Still better.

26. Menses appeared; abdomen not swelled; no pain in the side, nor any enlargement of the liver. Having pursued this mode of treatment for some time, I had the pleasure of seeing the girl enabled to pursue her ordinary avocations in life, leaving perfectly well. What has been very remarkable in connexion with this case was, that most of her family have died from the sequences of the same complaint.

LONDON HOSPITAL.—THE PUPILS AND  
MR. WALFORD.

*To the Editor of THE LANCET.*

SIR,—Though averse to every-thing like paper war, yet I cannot refrain from offering a few comments on the last letter of Mr. Walford, in reply to that from the pupils of the London Hospital. Our sturdy opponent was advised not to acknowledge what he calls our manifesto, on the ground of our insignificance. Here I would ask Mr. Walford, who, and what he is? Perhaps only a member of the College, and a licentiate of the Hall. If then we are in-

significant, most assuredly Mr. Walford's unimportant name will run parallel with the eight-and-thirty, for many of us are licentiatees, and hope to deserve the College diploma, yet not by "our lick-spittle adulation" of Mr. Headington, as our contemptible defamer would insinuate. "Why did they not defend the knight as well as the squire?" "I can solve the problem," exclaims our knowing insignificant, and as the truly illiberal idea shoots and swells his mighty mind, no wonder this huge colossus of foresight and penetration towers over the innocents of Whitechapel, the harmless little men of the London Hospital. Here again does Mr. Walford give a sad proof of a little mind, and commit the very sin unjustly charged on Mr. Headington in his letter of the 25th of September—"that of arriving at an age in which the heart never glows with generous sentiments." Poor man! I blush for him, I am ashamed of him, and wonder at that soundness of mind and intellect from which could emanate so much wisdom and sagacity in explaining the motive actuating some few of the thirty-eight pupils in replying to his letter. I am happy to inform Mr. Walford, that I am one of the few who will present themselves for examination during the presidency of our worthy and upright surgeon Mr. Headington, and I should be poor, pitiful, and mean indeed, if my opposition to Mr. Walford's sentiments arose merely from interested motives. I despise the idea as much as I despise the man from whom it could originate; both are alike contemptible. There are some parts in Mr. Walford's letter which I confess I cannot comprehend. What does he mean when he says, "Is a wish that every man of ninety-two may be so weak as Sir William, all the pity they can bestow on a poor old man?" No such wish could emanate from the pupils of the London Hospital as Mr. Walford would insinuate; it was indeed quite the contrary, as different as light from darkness. Nor does Mr. Walford credit the assertion, that the majority of our pupils were in your favour. Whether he will believe it or not, yet I can assure him that many of us would have hailed your election as the dawn of a brighter day, and one of our pupils actually wore the popular colours attached to his button-hole during the contest. I would ask you, Mr. Editor, if this savoured of fear, was this lick-spittle adulation to the surgeons of the hospital?

In conclusion, I must apologise for occupying so much of your valuable publication, and cannot help observing, with a smile of pity, the manner our letter has been turned and twisted by Mr. Walford to suit his abject mind. He says, indeed, a great deal and to no purpose, and will pardon me, if in my reply, I attach what he calls another

"tail-piece," quite, I think, as applicable as the last, that Mr. Walford's blustering importance

"Resembles ocean into tempest wrought,  
To waft a feather or to drown a fly."

I am, Sir,  
Yours respectfully,  
J. RICHARDS.

24, Old Ford Road, Bonner's Fields,  
Bethnal Green, Oct. 19.

With demonstrations that the solvent agent in digestion is the sub-carbonate of soda, &c. By C. H. Wilkinson, M.D., Bath. London: Ridgway. 1830. pp. 76.

Fate of the Colonies. A Letter to the Proprietors and Planters of the West Indies, resident in the Colonies. By R. Alexander, Esq. London: J. Fraser, Regent Street. 1830. pp. 31.

## TO CORRESPONDENTS.

Mr. J. N. and others. There was not time to send to Mr. N's house, but a gentleman from this journal was present at the inquest. The conduct of the condemned parties was highly indecorous and improper. Had it proved *injurious*, they should have received a severe castigation.

The letter of *An Old Pupil, A Censor of the Fellows*, &c., with many others, shall appear next week.

If A. R. K. was present at the operation, we should like to see him, if he will write and appoint a time for calling in Bedford Square. Our reporter was not present, but a gentleman on whom we can rely, has promised us an accurate account of the operation.

Mr. Spins. It was an unpardonable omission on the part of the Coroner; but this officer is not bound by law to insist upon the attendance of a surgeon.

The Index to our last Volume will *positively* be published next week, and in order that all parties may be accommodated, it will, besides being stitched up with the Number, be published in a separate form.

# THE LANCET.

VOL. I.] LONDON, SATURDAY, NOVEMBER 27.

[1830-31.]

## *Dublin Hospital Reports, and Communications in Medicine and Surgery.*

(Continued from page 238.)

IN continuation of our analysis of this excellent volume, we present our readers with an epitome of the most interesting papers which are contained in the second part. The first in order of these is a brief but valuable notice of diseases of the rectum by Dr. Colles, the celebrated professor of surgery in the Dublin College.

The first few pages of this article contain a masterly sketch of the symptoms and progress of organic stricture of the rectum. In this department much novelty could scarcely be expected, but there was room for a better arrangement of the several phenomena, and this object the author has satisfactorily accomplished. It is unnecessary to dwell here on the advantage thus gained, as it can only be appreciated by an attentive perusal of the entire paper. We pass to the first peculiar observation it contains.

"However constant in their attendance, or unvarying in their course, may be the symptoms of this disease, yet will the surgeon desire to be confirmed in his opinion by manual examination. Proceeding to make this examination, we often observe at the orifice of the anus the following appearance, which is, indeed, almost always present when the disease is seated near to the external sphincter; namely, at each side of the anus a small projection, which, on its external surface, appears as a mere elongation and thickening of the skin, but internally presents a moist surface, not exactly like the lining membrane of the gut, nor yet can we say that it is ulcerated; these two projections lie close together below, and divaricate above, presenting a resemblance to the mouth of a ewer. Whenever this external appearance exists, I feel almost certain of finding a stricture of the rectum before the finger is pushed as far as the second joint

No. 378.

into the gut. In some cases, however, this external mark has not been present."

Dr. Colles says that he has never met with a case in which the stricture was produced by means of bands thrown across the canal. He therefore concludes, and certainly with much justice, that this peculiar formation must be extremely rare. He adverts also to a practical point of some consequence, relating to the detection of stricture; namely, that in a few instances it has been seated so high that it could scarcely be touched with the point of the finger, until the patient was desired to "force down," when satisfactory evidence of its existence was immediately obtained.

The distinguishing features between stricture of the rectum and some other affections of this intestine, next engage the author's attention. Cancer, he believes, may always be distinguished by the leaden hue of the countenance, by the lancinating character of the pain, and, in the early stages, in which the diagnosis is usually considered the most difficult, he distinguishes the diseases by the comparative results of two manual examinations instituted at an interval of some weeks. "The cancerous ulceration will in the interval have destroyed some portion of the hardened wall of the intestine, and have thus produced a condition of the parts very different from that found in cases of stricture of the same duration." Schirrus of the uterus and vagina, and in the male enlargement of the prostate gland, are also attended by many of the phenomena of stricture of the rectum. Manual examination, the author asserts, is sufficient to distinguish between these diseases. An ulcer also is occasionally known to occur within the rectum, but this, if low down, becomes visible by expanding the anus, or by introducing a blunt polished gorget into the bowel, with its concavity towards the dis-

U

eased side of the rectum. The finger, too, if steadily pressed against it, will be received into the cavity of the ulcer, although in a hasty examination this part feels as if it were a ridge. In the last place, Dr. Colles notices a most important fact, which, in connexion with the anatomical details on the subject, communicated by Dr. Houston, and which we will subsequently notice, appears to us to be of much practical moment. We state the circumstance in the author's brief but descriptive language.

"Lastly, it may not be amiss to mention that we sometimes find in patients who are free from all symptoms of morbid condition of the rectum, that the finger in ano cannot discover any canal in the gut, the entire of the calibre above the sphincters being filled up with folds of the lining membrane; repeated observations, however, teach us that such a state is not morbid, as it in no way intercepts or disturbs the healthy functions of the intestine."

With respect to the influence of bougies in the treatment of this disease, he considers it calculated to alleviate the sufferings of the patient, but, on the other hand, he confidently asserts his conviction, that neither by the bougie, nor by any other mode of treatment, has organic stricture of the rectum ever been entirely cured. As a palliative method, however, he frequently employs the bougie, and he has also made it the vehicle for conveying ointments of various kinds to the seat of the disease; by means of a spiral groove running along the instrument, and which prevents the tightness of the anus and sphincters from rubbing off the application. Mercury, arsenic, iron, and *cicuta*, he also tried in vain, as far as the total cure is concerned. The existence of such a disease as spasmodic stricture of the rectum Dr. Colles disbelieves, and this scepticism he rationally founds on the negative evidence of a practice of twenty years. He admits of a spasmodic stricture of the sphincter ani, but considers it a very rare disease. In the only case of this which he has ever seen, the patient had been treated for spasmodic stricture of the rectum, but the result of inquiry into the progress and symptoms of the affection having convinced Dr. Colles of the true nature of the case, he passed a wooden globe three and a half inches in circumference, mounted on a stalk of whalebone, ten inches up into

the rectum without meeting any obstruction, and thus convinced his patient that his fears of strictured rectum were entirely unfounded.

The author next devotes a few pages to *vascular tumours of the rectum*, or what is vaguely denominated "hæmorrhoidal excrescences," a term which he considers inapplicable to their pathological structure. We quote his own words, but we must confess that we cannot perceive the force of his objection to the name in ordinary acceptation, since it is only descriptive of an acknowledged hæmorrhagic condition to which they are liable, and does not allude to their structural formation. The author's observations, however, are interesting in another respect, and throw much light on the pathology of the disease.

"I had an opportunity of examining the structure of these tumours in a patient who had died of another disease. On slitting up the rectum I saw three blood-vessels, each as large as a crow-quill, running for some way down the intestine, and then dividing into a number of branches; these vessels ramified very profusely, and each seemed by interweaving of its branches to form one of these tumours. The trunks and branches were covered only by the lining membrane of the intestine."

In the treatment of these annoying tumours, he prefers excision to the ligature, from the impossibility of preventing the occurrence of tetanus, which may be dreaded after the former, and from the facility with which the only difficulty attending the latter, namely hæmorrhage, can be controlled.

The following passage, describing his mode of operation, deserves minute attention. His observations on the prevention of hæmorrhage after the operation are extremely judicious; and it will be perceived that he makes a forcible objection to Mr. Hey's method of excising these tumours:—

"The following mode of operating I have found to be uniformly and permanently successful, and it is considerably less severe than that generally recommended. The tumours having been made to protrude by means of a purgative injection, I direct my assistant to pass a hook or common tenaculum through one or two of the largest, while I seize another lengthwise with a polypus forceps, then drawing the tumour a little

towards the axis of the gut, with a large pair of scissors passed behind the forceps, I cut off all that portion which is engaged between its blades. I then proceed in the same manner to remove those tumours which the assistant holds transfixed by the hook. By fastening and drawing out the tumour with the forceps, we much facilitate its removal by the scissors; proceeding in this way, I guard against these tumours being drawn up within the sphincter, as soon as the first had been removed. I do not think that any case will require the removal of more than three of these tumours, and not unfrequently the cure will be ensured by cutting off only two of them. When the operation is finished, the protruded parts generally lie within the sphincter; should any part remain out, it must be completely pushed in with the finger. In order to guard against the danger of hæmorrhage, I take care not to prolong my incision higher on the bowel than what I conceive will, when replaced, lie within the sphincter; for if we cut the gut higher up, this part, when returned, may bleed freely, from not having any surface closely opposed to it. Besides, we know that by cutting higher up we are in danger of cutting the trunk of the vessel, instead of confining our incision to the tumour which is composed solely by the convolutions of its very minute branches.

"I should be afraid to adopt Mr. Hey's method of cutting away all the protruding tumours, together with the skin at the verge of the anus, lest the patient should afterwards occasion the distress which a too contracted state of this outlet must occasion; for in one case, where, for the purpose of extirpating warts, a ring of skin at the verge of the anus had been cut away along with these excrescences, the condition of the patient was rendered truly miserable."

Dr. Colles' paper terminates with a few remarks on a peculiar "ulcer of the rectum." The mode by which this affection is recognised, we have already alluded to; of the remedy, the author speaks in the following terms:—

"The remedy for this disease is, to introduce into the rectum a convex-edged scalpel, and make an incision through the entire length of the ulcer, continuing it through the sphincter and dividing the verge of the anus; as soon as this wound has got into a state of suppuration, we should dress it and the ulcer, with some stimulating ointment introduced on a dossil of lint. The case goes on without interruption, although it is rather tedious and slow of healing. I need hardly say, that the final cicatrization will be promoted by the occasional application of the nitrate of silver."

The next article is an able and important paper by Dr. Houston, entitled, "Observations on the Mucous Membrane of the Rectum." As a companion to Dr. Colles' memoir, it is peculiarly opportune, especially since it completely elucidates the impassable condition of the rectum which Dr. Colles describes. In the progress of preparing some specimens of the natural position of the pelvic viscera, by hardening the parts with an injection of spirits, Dr. Houston's attention was arrested by the appearance of valvular projections in the rectum, formed by duplicatures of its lining membrane, and containing occasionally some muscular fibres. On repeating this mode of injection with a view to investigate this appearance, it was found to be one of almost invariable occurrence. The valves are usually three in number, of a semilunar form, their convex borders are attached to the sides of the rectum, and their general disposition is such as to form, by their being placed successively on different sides of the gut, a sort of spiral tract down its cavity.

The physiological rationale of this conformation, the author supposes to be a contrivance for supporting the weight of fecal matter, and preventing inconvenient pressure on the sphincter. His observations on the pathological relations of the valves are extremely interesting:—

"Considered in reference to disease, the valves or shelves thrown across the cavity of the intestine are fraught with still more importance. They may possibly become the most frequent seat of that morbid alteration of the inner membrane termed stricture. I have not, however, examined the subject with a view towards determining this question, but there are several facts which give probability to the conjecture. In the first place, this disease is generally confined at its commencement to a portion of the circumference of the gut; and, secondly, the seats of this occurrence correspond very much to the places where these valves are most frequently found, viz., near the orifice, about three inches up, or at the top of the rectum. There is still another more weighty reason why the surgeon should bear in mind the existence of these folds, that he may not mistake them for strictures in the gut, a mistake which, it is to be feared, has often happened to those who have reported such numerous cases of this disease, and which, by leading them to the frequent practice of bougies, may have brought on

the very malady which their instruments were intended to remove."

Dr. Houston gives a minute anatomical description of these valves, for which we have not space; their aspect is often horizontal, but usually obliquely upwards, and their depth is generally from half to three quarters of an inch. Mr. Crampton and the author concur in recommending a modified form of spiral bougie (something like a magnified cork-screw), corresponding to this newly-discovered configuration. Of this instrument, and of the valves, rectum, &c., *in situ*, an accurate, but coarse, lithographic drawing is appended to the paper. The distances, size, and anatomical bearings, are all represented with sufficient correctness, but every line is drawn as thickly as if it had been "laid on" with a house-painter's brush. Had there not been some tolerably good delineations by the same artist in this volume, we should have formed but an indifferent opinion either of the taste of the editors, or the state of lithography in the sister isle.

The remaining articles, with perhaps three exceptions, are so replete with interest, that our chief difficulty consists in making the selection which the limits of our analysis require. Taking novelty as our guide, we pass to the consideration of the papers on ophthalmic surgery by Dr. Jacob, and on the newly-discovered muscles for compressing the dorsal veins of the penis during the turgescence of that organ, by Dr. Houston, the author of the preceding remarks on the valves of the rectum.

Dr. Jacob subdivides his paper into different sections, commencing with remarks on stains of the conjunctiva and opacities of the cornea, produced by the application of nitrate of silver, acetate of lead, oxyd of iron, &c., a subject which, it appears, has attracted no attention from the several authors on the diseases of the eye, with the exception of a very brief notice by Mr. Lawrence, of the effect of nitrate of silver in producing a livid state of the conjunctiva, as given in our report of that gentleman's twentieth surgical lecture.

The stain produced by the continued application of lunar caustic, Dr. Jacob believes to be indelible. It seldom or never occurs, unless the remedy have been applied for six weeks or two months, and result from a

deposition of the olive oxyd of silver. The inconvenience to which it gives rise are two-fold, deformity and obstruction of vision, the first of which is so remarkable, that the acid little author avails himself of the occasion to remark, "that one practitioner, who was in the habit of using the solution very freely, so frequently produced this effect, that he has been able to point out his patients by the colour of their eyes." The second and more serious evil is one of very frequent occurrence, and, according to Dr. Jacob, is most frequently produced in the very cases in which the application is particularly recommended, namely, in sloughy ulcers of the cornea, or ulcers which have just cast off a slough. He does not think that surgery will be at all injured by a diminution of confidence in this, which he bitterly terms a "popular" remedy. He agrees with Mr. Lawrence in admitting, that he does not understand how this caustic can act beneficially upon the diseased eye; and, finally, with reference to the experience of others in its favour, he observes in the same snappish spirit which invariably characterizes the animadversions of this clever, but irritable critic,—“The nitrate of silver may often have been beneficial in the hands of such a man as Scarpa I believe, but I think, that if this able surgeon had seen *its general effects in the hands of others*, he would not have given it so unqualified a recommendation.”

He next alludes to the analogous effects of the application of the acetate of lead. The phenomena which this occasionally produces are so ably described, that we shall transfer the author's words to our columns:

“The injury produced by the nitrate of silver is seldom so great as that which more frequently follows the use of the acetate of lead, yet I do not find any mention of the latter in books. If a solution of the acetate of lead be applied to the eye when the cornea is suffering from an ulcer of a particular character; the acetate is decomposed, and a white precipitate is deposited on the ulcer, to which it adheres tenaciously, and in the healing becomes permanently and indelibly embedded in the structure of the cornea. The appearance produced by this cause cannot be mistaken, its chalky impervious opacity distinguishes it from the pearly semi-transparent structure of even the densest opacity produced by common ulceration. The degree and

form of the opacity are varied as the original ulcer was varied. If the original ulcer was deep and circumscribed, the opacity is chalky white, dense, and defined. If the original ulceration was superficial and diffused, or composed of numerous small specks of ulceration scattered over the cornea, the opacity presents the appearance of several irregularly-shaped dots or specks of a dirty-white appearance. - - - - The opacity appears to be produced at once, and by a single application. I have seen it the day after a drop of solution of acetate of lead had been put into the eye by mistake. - - - - How far the stains and opacities to which I have alluded admit of remedy, I cannot determine. I have tried acid solutions, and in the recent deposits of the salts of lead, silver, or iron, on an open ulcer, I have scraped the surface with the point of a needle, and thus removed the foreign matter; but as this cannot always be practised with safety, and may cause a larger opacity of a different character, its utility may be questioned."

Dr. Jacob finds, that whether in health or disease, the presence of an alkali in the lachrymal secretion may be known by reddened litmus being restored to its colour by the tears. He collected a considerable quantity of the precipitate, which was submitted to analysis by Dr. Apjohn, with the following results:—

"The supernatant liquid having been removed by a sucking tube, the precipitate was digested with moderately strong acetic acid, which effected its partial solution with considerable effervescence; the solution having been decanted, the residual matter was well washed with distilled water, and then treated with a few drops of strong nitric acid; this caused it to disappear, nitric oxide being at the same time evolved, and the solution, when evaporated to dryness, yielded a residuum of a deep yellow colour, entirely destructible by heat. The solution made by the acetic acid was next evaporated to dryness, and the saline residuum repeatedly digested in alcohol, which took up the greater part of it, and was found on examination to contain acetate of lead; the portion which resisted the solvent action of alcohol appeared to undergo slight diminution by digestion with distilled water, and the solution was rendered cloudy by nitrate of silver: this argues the existence of chloride of lead. Finally, what remained after the action of the water, exhibited before the blow-pipe the properties of phosphate of lead."

We have not space to pursue Dr. Jacob's observations any farther; suffice it to say, that much practical information is afforded

in comparatively few pages. Whoever may peruse this author's writings, certainly need not dread the invasion of ennui, for wherever Dr. Jacob has an opportunity, he barks with so much spirit, that even on the dullest subject he is extremely amusing.

We now turn to Dr. Houston's discovery of the "*compressores venæ dorsalis penis in man*," with a brief abstract of which we shall conclude this notice. He introduces the subject by an outline of the anatomical conformation of the penis in the different tribes of mammalia, and points out the uniformity of structural type, &c. in the entire. Thus the cavernous bodies have been determined by several processes to be vascular, entirely composed of vessels, chiefly veins, interwoven with each other in the most complicated manner. The corpus spongiosum urethræ is likewise formed of innumerable blood-vessels, and in the different orders chiefly varies in its comparative magnitude with the other parts of the penis. In all, a striking uniformity exists with respect to the mode in which the several veins are collected into one general trunk, which, after passing beneath the arch of the pubis, is again distributed over the aides of the bladder and prostate gland.

Having premised this general view of the anatomy of the parts, Dr. Houston proceeds to investigate the nature of the turgescient state of the penis; and this, in limine, he is disposed to ascribe to sanguineous accumulation in the veins; that it cannot result from arterial congestion, he argues from the rigidity of the tunics of arteries, and from experiments on living animals, in which he has never been able to discover any difference in the fulness of the arteries in the most extreme state of turgescence or collapse of the organ.

He next proceeds to investigate the mode in which this venous congestion is affected; he notices the disproportionate size which the *venæ dorsales* bear to their accompanying arteries, and dwells at considerable length on the incompetency of the *erectores penis*, *acceleratores urinæ*, and *transversales perinei*, to accomplish the compression of the veins, which would be necessary to induce the erectile state. Haller's vague opinion of disproportionate influx of blood he justly rejects as insufficient to afford a rational explanation. Finally, he adduces

a number of extremely curious and novel anatomical facts, by which he demonstrates a mechanical apparatus provided in all the tribes of the mammalia for arresting the reflux of blood by the dorsal veins. We subjoin sufficient extracts from the paper to elucidate the subject in a satisfactory manner:—

“My attention was first directed to this subject by a communication made to me by the late ingenious Mr. Shekleton. In dissecting the penis of a dog he discovered two muscles connected with the *venæ dorsales*, and admirably adapted for making such compression on these vessels as to obstruct the current of blood in their canal. But the melancholy event which deprived the world of the fruits of his genius, also stopped his further prosecution of this subject. I afterwards found, on inquiring as to the originality of the observation, that the great Cuvier, whose extended researches have left little room for further discoveries in anatomical science, makes notice of the existence of such muscles as these. His allusion to them is, however, only cursory, and his opinion regarding their functions undecided. The result of my own observations respecting their existence in different animals, and the extent of their influence in producing erections of the penis, together with the discovery of a similar apparatus connected with the lingual veins of the chameleon, I shall now proceed to detail. The muscles are situated between the arch of the pubis and the penis. I propose to name them *compressores venæ dorsalis penis*. I have found them readily in every animal which I examined. In the dog, wolf, jackall, bear, badger, cat, raccoon, coati-mondi, marmot, aguti, horse, seal, &c. &c., and encouraged by the certainty of their existence in these animals, together with the general resemblance which the muscles, blood-vessels, and erectile tissue in them, bears to the same structures in the human body, I persevered in my search for them in man, by a variety of dissections, until at length I discovered them on the 15th of July, 1830, and satisfactorily demonstrated them to many of the pupils and several professors in Dublin, among the latter of whom I have the privilege of enumerating Drs. Cusack, Jacob, and Graves, whose expressions of satisfaction as to the presence of the muscles, and their favourable arrangement for exerting pressure on the *vena dorsalis*, afford abundant testimony of their existence.”—pp. 468—470.

Dr. Houston next gives a minute anatomical description of these muscles in the dog, monkey, bear, badger, cat, aguti, and

horse, and lastly in man, in whom he describes them thus:—

“In man, the *compressores venæ dorsalis*, are less distinct than in most of the mammalia. They arise from the rami of the pubis, above the origin of the *erectores penis* and *crura*, and ascending in a direction forwards are inserted above the *vena dorsalis* by joining with each other in the mesial line. They form a thin stratum of muscular and tendinous fibres, about one inch long and three quarters of an inch broad, and may perhaps be looked upon as portions of the *erectores penis*, which, instead of being inserted into the sides and lower part of the *corpora cavernosa*, mount over those bodies, to exert their compressing influence on the *vena dorsalis*. They enclose between them and the penis the vein, arteries, and nerves, of this region. Their anterior fibres are distinguished from those of the *erectores*, by the fibrous attachment of the *crura* to the pubis; their posterior margins are kept distinct from the front part of the *levator ani*, known under the name of Wilson’s Muscles, by the pudic artery, which divides them in its course towards the dorsum of the penis.

“The best procedure to display these muscles is the following. Detach the bladder and levator ani with the hand from one side of the pelvis; then divide with a saw the pubis and ischium about one inch from the symphysis, and break off the bones at the sacro-iliac articulation: next dissect away carefully the remaining portion of the pubis from the symphysis, periosteum, and *crura penis*, and then the *compressores venæ*, bearing still their natural relations to the *crura* and other muscles, may be exposed with very little difficulty.”—pp. 472—474.

In emaciated persons new muscles are detected with very great difficulty. Their action is indisputably proved by the fact, that by stretching them in the direction of their fibres, the current of fluid through the dorsal veins is completely arrested. Finally, Dr. Houston relates some striking experiments on dogs, in which the ligature of the dorsal veins produced permanent turgescence of the penis, which was only relieved when new channels were established for the evacuation of the venous blood. On the physiological interest of these statements we will make no further comment, than that they are in the highest degree creditable to the author’s originality of genius and anatomical perseverance. In the same paper he describes ably and beautifully the analogous structure of the chameleon’s tongue,

which our readers will probably recollect is an erectile organ most wonderfully adapted to the prehension of food, &c. We cannot leave this subject, without bestowing our warmest praise on the exquisite engravings which accompany the essay.

We regret we cannot extend our analysis to several other papers of great merit; we will particularise that by Dr. Marsh on a convulsive disease affecting young children, which he states may be denominated spasm of the glottis; we may also mention a practically useful, but rather quackish communication from Dr. Cheyne on the efficacy of small bleedings in restraining hæmorrhage from the lungs. Mr. R. R. Gregory's concise report of his newly-established lying-in hospital is also highly creditable, and will perhaps elicit a few remarks on another occasion. Before we conclude we have a disagreeable duty to perform; one which, without metaphor, sets a sting in the tail of our observations: it is that of advising Mr. West never again to venture into such good company on such a frivolous ground as that of his "case of psoriasis successfully treated," &c. &c. Reputations are not to be earned by the authorship of papers so insignificant as this.

## ST. THOMAS'S HOSPITAL.

### CLINICAL LECTURE

DELIVERED BY

DR. ELLIOTSON,

Nov. 8, 1830,

(Concluded from page 275.)

### MALINGERING.

I now proceed to make a few remarks on the impositions which are frequently practised upon us. Writers on forensic medicine divide these impositions into pretended diseases, *morbi simulati*,—diseases which have really no existence; *morbi dissimulati*,—diseases which really exist, but where health is feigned; and diseases which are falsely imputed to others,—*morbi imputati*. Now, people frequently pretend to have diseases for the purpose of avoiding punishment. Thus insane people are not capitally punished, and criminals will therefore feign in-

sanity. Pregnant women (pregnancy, however, is not a disease, a pathological state, but a physiological state, and the word *morbi* is therefore an improper term for the whole of these things) are not executed, and the punishment, therefore, is delayed in the case of pregnancy until delivery has taken place. Soldiers and sailors will pretend illness to avoid the duties of their stations, and to be dismissed the service and provided for accordingly. Diseases are often *dissembled*,—health is pretended, in order to avoid the disgrace and disadvantages which are perhaps attached to the particular condition. Single women dissemble pregnancy that their characters may not suffer. Again, disease is sometimes *imputed* to persons in order that the accusers may get possession of their property, or obtain the management of them in some way or other, and not unfrequently out of mere spite, from a desire to be revenged upon and to disgrace another.

Now these stratagems have been adopted from the most ancient times. But I will speak only of the *morbi simulati*; for the *dissimulati* and *imputati* I shall not have time to consider, and there is far less difficulty in ascertaining the *morbi dissimulati*,—the existence of disease when health is pretended, than when disease is feigned; for if a person have a disease, it is very difficult for him to conceal it—if one is ill, it is not an easy matter to appear well. Again, as to *imputed* disease, the alleged affection does not exist, and the individual himself is practising no deceit: the disease is merely imputed to him by others, and you have as full an opportunity of judging of his real condition as they; for no one will think of imputing a disease which gives no external symptoms, of imputing, for example, chronic rheumatic pains to another, because these are insensible to all except the patients. But pretended diseases, *morbi simulati*, are very numerous, and the deceit is exceedingly ancient. You will recollect that Ulysses pretended madness in order to avoid going to the Trojan war, and David, too, pretended to be mad, or rather imbecile, when he was afraid of Achish, the king of Gath, to whose court he had fled from Saul: and hence you read in the first book of Samuel, chapter xxi verse 32, that "He changed his behaviour before them, and feigned himself mad in their hands, and scrambled on the doors of the gate, and let his spittle fall down upon his beard."

I have had far less experience in these matters than gentlemen who practise in the navy and army, and it is wonderful to read what is sometimes borne, what severity of punishment is undergone by sailors and soldiers, in order to avoid duty, to be discharged and to get pensions. They will

bear the most severe medical treatment, starving, blistering, and the application of caustic; they will bear confinement by themselves; they will keep up inflammation of the eyes by applying cantharides and sulphate of copper, day after day subjecting themselves to the greatest pain, and exposing themselves to the greatest hardships, till they at last procure their dismissal, when they will sometimes confess the cheat. No one could have the least idea that human nature was capable of practising such deceit, and of undergoing such suffering for the purpose of carrying it on. Dr. Cheyne has furnished us with very good information on the subject, in a paper in the fourth volume of the Dublin Hospital Reports, and Mr. Copland Hutchison, in his Practical Observations on Surgery. Dr. Cheyne describes the deceptions witnessed by him in the army, and Mr. Hutchison those which are observed in the navy. In Hennen's Military Surgery the subject is also well treated. Dr. Cheyne says, "I never saw a more humiliating picture of depravity or perversion of reason, call it what we may, than I have witnessed in a ward filled with soldiers labouring under ophthalmia (!) most of the cases, as I have learned from the surgeon in attendance, being fictitious. The methods by which inflammation of the eye is produced and maintained, have not all been brought to light, but quick lime, infusion of tobacco, the gonorrhoeal discharge, cantharides ointment, nitrate of silver, blue-stone, and other metallic salts, are probably among the most common irritants employed. Inflammation thus caused is most painful, and is kept up under every privation which can make life miserable; locked up in a dark ward, and permitted to have intercourse only with the officers of the hospital, nurses, and orderlies, confined to diet which, from the absence of every stimulating material, is most disrelishing, suffering under painful external applications, and nauseating internal medicines, phlebotomized and leeches till their complexions are bloodless, their pulse hæmorrhagic, and the frightful train of nervous symptoms which excessive blood-letting produces is established in the system. All these evils, in many cases, have the effect but to confirm the soldier in his determination to destroy one or both of his eyes that he may be dismissed from the service, with the chance of a small pension." "Wonderful, indeed, is the obstinacy which some malingerers (the name given to these impostors) evince. Night and day they will remain with the endurance of a fakir, in a position the most irksome. For weeks and months many men have, with surprising resolution, sat and walked with their bodies bent double. Some have continued to irritate sores in the leg until

their cases became so bad as to require amputation of the limb, and many instances have occurred in naval and military hospitals of fictitious complaints ending fatally." It is thought that methods of deception have been reduced to a system, and preserved in many regiments, and handed down that those who think proper may try them, and a kind of freemasonry exists, which, preventing the exemplary from informing of the worthless, renders it often very difficult to detect the method of deceit.

One of the diseases most commonly pretended is fever. Persons will take spirits or stimulants of some kind to excite the pulse, to heat the skin, and parch the mouth; but in these cases, unless intoxication, or an approach to it, is produced, there is not that heaviness and distress of countenance which is seen in fever. The deceit may frequently be detected by the smell of the breath, and if you confine them in a room where there is no opportunity of applying the stimulus again, first stripping them to ascertain that they have none on their persons to keep up the symptoms, these must soon go off. Some persons, however, will manage to sustain the irritation by putting a clove of garlic up the rectum. As it is right, however, in real fever to clear out the bowels, this cannot long occasion difficulty. So with respect to any feigned disease which, to be kept up, requires continued irritation, whether ophthalmia or any sore, if the parties are confined so that they can obtain no access to the necessary stimulants, it will of course cease. The complete prevention of access to means of deceit, is the great mode of detecting and removing a large class of feigned diseases. Tobacco and digitalis are said sometimes to have been taken to produce the opposite effect on the pulse,—to depress it.

Deafness and dumbness may be counterfeited, in places where the person is unknown. There was a young man in France, who, in order to avoid the conscription, pretended to be deaf and dumb, and kept up the deception for four years. He travelled through France, Germany, Spain, and Switzerland, and wished to appear like young Telemachus in search of his father. He professed to have been instructed in the Abbé Sicard's establishment, but on being confronted with some of the Abbé's pupils, he proved to be ignorant of the signs taught in that school; and from fear of being confronted with a cook from whom he had learnt to make pastry, he opened a book and read aloud. He had been remarkably consistent for four years in his plan, but failed in one point. In writing he substituted, through ignorance (having been indifferently educated), the *g* for the *c*, thus making it probable that at one time he had known that

the sounds of both were much alike in some words. This he was not likely to have learnt but by his ear. The Abbé de l'Epée, and a whole committee, were once deceived by an impostor, who pretended to be deaf and dumb. In one instance a man pretended that he was born deaf and dumb, in order to obtain his discharge from the French army; but the examining physician, Dr. Fodéré, going behind him said, "You shall not persuade me that you are deaf, and if you will disclose the truth, I will procure you your discharge." "Well then," said the poor deserter, to the surprise of all, "I am not deaf."

A loud noise suddenly made in the ears of such persons when they are unaware of the intention, will sometimes produce a degree of agitation, notwithstanding all they may do to avoid showing it, and their power of hearing has been thus discovered. Sometimes the discovery has been made by talking in their presence of violent measures for their recovery; by saying that red-hot irons are the only remedy for their complaint. This has frequently produced agitation of the countenance, or a quickness of pulse, which showed that the conversation had been overheard. Stratagem, therefore, is another mode of discovering whether diseases are feigned. A very fine case of imposture occurred in this country, in the case of Miss Macavoy, at Liverpool, a few years ago. She professed to be able to see, not with her eyes, but with her fingers. So convinced were some persons that this was not a case of imposition, that a quarto book was written to prove her veracity. Goggles were placed upon her eyes, but it was easy for her to see in spite of them, by holding her head in different directions, so that the light might pass under the edges. The only satisfactory proof would have been to have put her head in a bandbox, and bring it down so closely around the neck, that it would have been impossible for her to see the light from any part. There is great difficulty in so placing any thing over the eyes as totally to exclude the light; and she actually was obliged to hold her head in different directions when the goggles were placed upon her eyes, before she could see any object; but certainly there would have been no occasion for this, had she seen with her fingers. The whole thing indeed was very gross, for, amongst other wonders, she declared that by touching convex lenses placed between her and objects, the objects appeared larger, and by touching concave lenses they appeared smaller; the absurdity of which is manifest, for you know that the *focus* of a lens is at a distance from the glass itself, and it should have been, therefore, by holding her fingers not in contact with the glasses, but in the focus of

the glasses, that the objects should have appeared enlarged or diminished. The impossibility of this statement ought alone to have been considered proof of deception. No experiment was made to ascertain whether the point of the lens she touched was in a line with the object, and whether an opaque substance interposed in this line prevented her power. An acute investigation, therefore, with the view of detecting any incompatibility or impossibility, or any deviation from the usual character of a disease, is a third mode of ascertaining the existence of a deception. Short and long sightedness are sometimes pretended, and may be detected by substituting one glass for another, without letting the party know of it, and then observing the effect; for if the complaint is feigned, the effect of the glass calculated to remedy the real defect will be to produce that difficulty of which they complain; and if you substitute a plain glass, while they think it is a lens, they may declare at once that they can see clearly.

Amaurosis is sometimes pretended, and may sometimes be with difficulty detected, because the structure of the eye in amaurosis is frequently entire, and the iris in amaurosis sometimes contracts. If the pupil were always insensible or sluggish, you might detect the imposition; at least, by cutting off the patient from access to belladonna and some other narcotics, which, you well know, smeared around the orbit, dilate the pupil, and render the iris motionless for a time. But blisters and caustic, and similar means, are often proper remedies in amaurosis, and they are, therefore, suitable when it is feigned. They are very proper in pretended amaurosis, and far more likely to cure it than the real disease. Electric shocks are highly proper in many cases of palsy, rheumatism, and convulsions; and Dr. Cheyne has known these cure many feigned instances of these diseases. My patient was rapidly getting well under electric shocks, and may probably soon be cured by them in the hospital where he is at present. A writer on forensic medicine, Mahon, mentions a case of a young man who feigned amaurosis so well, that on being led towards the edge of a river, he walked on and tumbled in. After obtaining a promise of his discharge, he confessed the deception, and took up a book and read. Palpitation is sometimes feigned. Dr. Hennen mentions the case of a soldier who feigned great palpitation, but when compelled to throw his head back, so that he could not lessen the cavity of his chest, the palpitation diminished very much. It appears that he did so by lessening the chest, so that the front of it was brought close to the heart, and this organ was felt beating against the

parietes; but when he was so placed that he could not contract his chest, the palpitation was found to be exceedingly slight. Mr. Hutchison says that white hellebore is often used by sailors to excite palpitation.

As to feigned jaundice, that is easily discovered, because the sclerotica cannot be coloured; and the colouring of the skin may be washed off. The impostors, too, generally forget to whiten the fæces, and to give urine the appearance of porter, at least at the same time to make it yellow, so that this hue may become apparent on holding the vessel on one side. It is said also, that general debility and exhaustion have been imitated by bringing the face in contact with the fumes of sulphur; but here detection is easy. Hæmorrhage from the stomach, lungs, rectum, urethra, and vagina, is frequently feigned. Blood is sometimes obtained in these cases by sucking the gums; or pricking and sucking the fingers. I had a case last year in the hospital in which the patient pretended to spit blood from her lungs, which I found she sucked from her gums. When the blood is so copious that they must employ the blood of some brute,—generally bullock's blood, confinement and the prevention of access to this, will soon cure the complaint. Hæmorrhage from the rectum is also imitated by injecting clysters of blood, but the same means will detect this description of fraud. The imitation of bloody urine it is said may be effected by eating the prickly pear, and some red roots which have the property of dyeing the urine red; but if you come to examine the urine, you will discover no coagulum, no flocculi, no red lumps, and when evaporated there is no such sediment as dried blood. I recollect a woman showing a number of small substances which she declared she passed in great agony with her urine; they were found to contain carbonate of lime, which very rarely constitutes urinary calculi, but abounds in the bones. They were shown to Dr. Wollaston, who, on looking at them through a lens, discovered a hole in the centre of each, and clearly made out that they were the vertebræ of sprats.

But I believe that among the diseases most frequently pretended in civil life, are the various convulsive and spasmodic affections. Epilepsy is the most frequently chosen. The foaming at the mouth is sometimes produced by soap; and some go so far in these enlightened times as to effect the dilatation of the pupil by the extract of belladonna. Generally, we are told, you may discover cases of assumed epilepsy, by observing that the pupil is not dilated, and by producing violent pain, so that they are obliged to show signs of sensibility. Many cases of feigned epilepsy may be detected by

bringing before the persons red-hot irons, and if this fails, by commencing their application. But where that is not thought right, you may generally produce a sufficient effect by passing the thumb nail under one of the nails of the patient, who, if feigning, will probably cry out, or withdraw his hand, from the violent agony which this occasions. Dropping a little spirit into the eye has the same effect. The employment of soap may be detected by the smell. You will always observe, that persons who are feigning epilepsy, are not addicted to falling into the fire, nor into water, nor against the corners of buildings, nor in any situation by which they will be hurt; but usually tumble in some safe spot, where they can receive no harm. An impostor has been discovered by placing him in the fit on a high table near the edge. But other convulsions will be imitated also, and it may be difficult to discover the real nature of the case, because there is no end to the variety of convulsive diseases. There are many so singular, that you would be unable to decide at once, and to say, "Here is a thing which I never saw or read of, and which is a deception." It may never have been heard of by us, and yet the inference that it never occurs may be false. On that account I hesitated to express a decided opinion relative to this man, and say the case was a deception. Deceptions of this kind were more common formerly than they are now; for, formerly, persons could, with little fear of detection, say that they were filled with the Holy Ghost, or possessed by the devil or bewitched and that such and such individuals were the cause of it: the former in order to prove themselves holy, the latter wishing to occasion mischief to some of their neighbours. In former days, medical men listened like the rest of the public to these tales. Sennert says, that the devil will cause insanity, and make the person speak a strange language; and that the reason why atrabilious persons are liable to melancholy is, simply that the devil is fond of wallowing in black bile, and therefore enters them for a treat, and, that if the physician purges it away and cures the complaint, the cure is effected, not by the removal of a bodily disease, but by the purging away of that into which the devil had gone for his delight—the *balneum diaboli*, as it was termed, so that the devil leaves the patient, who thus is melancholy no longer.

Some physicians, says old Avicenna, have seen what the devil can do. Cornelius Gemma, a physician of the sixteenth century, writes, that a cooper's daughter, named Catherine Geralda, had such strange passions and convulsions, that three men sometimes could not hold her. She discharged a live eel a foot and a half long,

which he saw and touched (but unluckily he did not see it come forth), and the eel afterwards vanished. She vomited some twenty-four pounds weight of fulsome stuff of all colours twice a day for fourteen days, and afterwards balls of hair, pieces of wood, pigeons' dung, coals, stones *with inscriptions*, parchment, goose dung, pieces of glass, *et hoc*, says this writer, *cum horrore vidi*; he saw all these things, no doubt, but not *in transitu*. The doctors attributed all to the devil, and gave her over to the clergy. Marcellus Donatus relates a similar case, and supposes it happened, *certe non alio quam demonis astutia et dolo*. Physicians, however, have generally been amongst the most enlightened of mankind, and Voltaire says he should advise the devil always to address himself to parsons and never to doctors, if he hopes to flourish. "*Je conseille au diable de s'adresser toujours, aux facultés de théologie, et jamais aux facultés de la médecine.*"

In Plenk's Elements of Forensic Medicine, published only in 1781, you will find demoniacal possessions arranged in systematic order, like other diseases, so that there is the *demonia vera*, *demonia simulata*, *demonia dissimulata*, *demonia imputata*, and *demonia imaginaria*. The *demonia vera* is particularly distinguished by the dislike of the patient to holy water, upon the approach of which, even unseen by him, he is sure to become outrageous. Though enumerated by Plenk, he, however, plainly believes nothing about it, and cunningly refers us for the dissipation of our doubts to the clergy,—*an demon potestatem habeat a theologis queri debet, &c.*

You must consider me as having made a few cursory observations only upon this subject, as it is too extensive for a single lecture; I must refer you to the works which I have already mentioned, and those upon forensic medicine; in them you will find cases without end. There was once a girl in Strasburgh who grew as large in the body as Sterne's stranger who entered Strasburgh had done in the nose, and a suspicion arose of her being pregnant. The time arrived at which she should be brought to bed, but it passed away, and she remained as large as before. In fact, she continued to increase for thirty-nine years, and was regarded as such an object of compassion, that all the charitably-disposed ladies in the neighbourhood were moved towards her, and their sympathy so strongly excited, that she was well supported all her life without work. She resolutely persisted in allowing no medical man to go near her. After thirty-nine years she died, and the disease was found not in her body, which was of the proper size, but in her wardrobe, where a large cushion, 19 lbs. in weight,

was discovered, which had given her a goodly bulk, and made her waddle in her walk, as though she had a heavy tumour of the abdomen.

A trooper of the 12th pretended that he had lost the use of his right arm, and after resisting severe hospital discipline for a great length of time, succeeded in procuring his discharge; and when fairly seated on the top of the coach, waved his *paralytic* arm in triumph, and cheered at his success. A militia soldier pretended that he had lost the use of his lower extremities, and was discharged. He afterwards caused himself on a field day to be taken in a cart in front of the regiment, which was drawn up in a line, had the cart driven under a tree, upon which he hung his crutches, leaped out of the cart, sprang three times from the ground, slapped his breech, and scampered off at full speed.

Now, though we may sometimes be thus imposed upon, there is a caution which I am very anxious to impress upon you. It is possible that the disease may be real which you suppose to be pretended; and if you were to pronounce an opinion that it was a mere deception, certainly the consequences must be very painful to your feelings. I confess that I would rather myself be deceived a thousand times than say once in my life that a person was an impostor who should not turn out so. It was on this account that, although I have such a strong suspicion of the man to whose case I have alluded, I would not say he is an impostor, and did not adopt any measures which would not be calculated to remove the complaint if such a complaint existed. I certainly should not like to be deceived, but you must remember, that if you make one mistake you do a serious injury to a fellow creature. It may, perhaps, hurt our pride to be deceived and overmatched; but though our pride may not be hurt, although you are not overmatched by another, when you pronounce a man to be an impostor who is not, you must have in this case to reflect that you had been deceived by yourself. It is better to be deceived by a thousand persons and injure no one, than to injure one individual. Your pride may not suffer in the latter instance, but the error of judgment is just as great as if you had permitted another person to deceive you. In 1804 or 1805, a soldier complained of great uneasiness in the loins, was treated as a malingerer, and sent to punishment drill, at which he was kept till the tumefaction of a lumbar abscess appeared upon his back, of which the poor fellow died. Fodéré confesses, that for fifteen years he refused his certificate to a young soldier who complained of excessive pains, sometimes in his head, at others in his chest, and at length died, when no disease was

discovered; so that Fodéré concludes his complaints had been real, and he had been exhausted by mere pain. "From that time," says this writer, "I have often preferred being indulgent to running the risk of being unjust again in a single instance." Had this happened to me, I should never have been perfectly happy again.

With respect to all these deceptions, the best course is to have the patient watched. If it be an affection which is only continued by the application of artificial means, from time to time, then it is proper to direct the patient to be confined from access to them. But suppose it is a case in which no stimulants, nor particular substance, is required to keep it up, then your course is to resort to stratagems of the various kinds which I mentioned, such as threatening the man with punishment in his hearing if he pretend to be deaf, or by writing it down if he pretended to be blind, and by noticing the effect on his pulse. In all cases it is important to examine whether there is any inconsistency or impossibility in the description, or deficiency in the detail of symptoms. I would never have recourse to violent measures, or any severity, until the suspicion was sufficiently strong to justify them. The measures we employ to cure many diseases are violent enough of themselves, and sufficiently painful, and may with propriety be employed to cure the disease and be quite as effective if the disease is altogether feigned. Again when every thing else fails to disclose the deception, and you still have every reason to believe that it is a trick, then it is best to take the patient on one side, as Dr. Cheyne suggests, put him upon his honour, and promise him forgiveness if he will acknowledge the cheat. When you reflect that in a great number of instances individuals really have a powerful motive for the deception, that is to say, to avoid some very hard service, or duty, or punishment, or to get support when they are starving, and that the disease may really exist in some degree, and be only exaggerated, there is still more reason to be cautious. It is true that there are idle, worthless, dissolute persons, devoid of principle, all who feign diseases; and I would advise you always to keep a sharp look-out, and to be active in your investigations. But when you remember also that there is a possibility of your being deceived, or, that if you are not deceived, but perfectly right, the individual from his hard and trying circumstances is, perhaps, to be pitied, I must repeat that I would rather be deceived a thousand times, than run the risk of pronouncing one really diseased person to be healthy.

It is to be remembered likewise, that although patients often deceive us, practitioners are sometimes as great deceivers as

patients. If there are deceiving patients there are deceiving doctors, and, to say nothing of those regular practitioners who disgrace the great body of us by their quackish habits, let us remember, that notwithstanding the laws and privileges of the Royal College of Physicians, of the Royal College of Surgeons, and of the Worshipful Company of Apothecaries, quacks exist in shoals, and can flourish in this metropolis under the walls of these three authorised corporations, and set them all at defiance; for, to suppose that any one of the three would not instantly suppress every quack and impostor, had it the power to do so, would be to accuse it of the neglect of a solemn duty. Nay, still more than this, a quack may not only gain 12,000*l.* per annum by his tricks, in spite of all these bodies, but is allowed to kill the patients who fall into his hands, at the rate of 250*l.* a head.

## WESTMINSTER MEDICAL SOCIETY.

*Saturday, November 20, 1830.*

Mr. BACOT in the Chair.

### INTESTINAL HÆMORRHAGE.

Dr. SOMERVILLE, before the regular business of the evening commenced, related the case of a young woman aged 26, the circumstances connected with whose illness seemed to him of rather peculiar interest; she had menstruated irregularly for some time, and occasionally the secretion was very abundant, but on the whole this condition did not seem to influence her disease. Since the age of 19 she had been subject to discharges of blood from the rectum, which usually happened after the expulsion of the *feces*, when she would suddenly experience a sensation as if something burst within her, which might be referred to the course of the colon. When this had lasted a little time she began to feel extremely faint, passed a trickling stream of blood, and fainted away. In this manner the disease went on till she was 26; various remedies were ineffectually employed, and she gradually sunk. On the whole there had been so little general constitutional disturbance during the progress of the case, that he could not attribute it to any malignant cause, neither was there any evidence of any tumour existing in the abdomen. On dissection, nothing more was found than an aggregation of vessels in different parts of the rectum, occurring in small patches, converging towards a common centre. The members of this family seemed altogether affected with an hæmorrhagic tendency; a brother had died of the same complaint, a

sister had, in early life, been subject to violent epistaxis, and another was near losing her life in consequence of the removal of a tooth.

Dr. GREGORY inquired if the patient had used mercury. Dr. Somerville: Over and over again; if Dr. Gregory knew the practitioner who at one time treated her, he would have a certain guarantee that she had been sufficiently mercurialised. Mr. Bacot, with reference to the detection of abdominal tumours, said, that the best way to detect them was by placing the patient on his hands and knees, when the abdomen becomes pendulous, in which manner tumours will often be detected which would otherwise escape observation.

Dr. GREGORY stated, that he was unwilling to delay the treat Dr. Granville would afford the Society, but was induced to put the question in consequence of all that had been lately said about the influence of mercury in abdominal hæmorrhage. One or two cases had recently occurred to him, in which he had used calomel and jalap very freely, and was rather divided in opinion as to which of these medicines was entitled to confidence; he was inclined to consider the mercury as the active agent, but he had recently seen a case, with Dr. Duffin, in which the effect of the mercury was to produce bleeding of the gums to such an excess that the patient's life was very seriously endangered.

Mr. COSTELLO said, that cases had been lately published, by Spinaldi, in Italy, in which the *secale cornutum* was administered in free doses, from six to ten grains, at short intervals, with extraordinary good effect.

POLITICAL CONDITION OF MIDWIFERY IN THE METROPOLIS.—PROCEEDINGS OF THE OBSTETRIC SOCIETY.

Dr. GRANVILLE: I regret, sir, that my friend Dr. Gregory should have made use of expressions calculated to lead the Society to expect more than it is my intention to offer; indeed, instead of a treat, I fear that as far as I am concerned, it will only lead to their disappointment. The question I have selected to lay before you this evening is one, respecting which I will say that I regret deeply there should be any necessity to bring it forward; that there should be a total want of legislative protection, not only to the practitioners of the obstetric art, but what is of much greater importance, to the public at large, whose lives, more precious than property, and consequently more entitled to legal defence, are in this particular most seriously and fatally affected. The state of medical police in the English metropolis is such as it is painful to consider,

so inferior is it in every respect to what I have a right to expect in a nation so abounding in scientific institutions, where medical learning, at all times, has flourished to so great an extent; yet here, in a department of the medical profession, the practice of which involves, at the same time, the existence of two individuals, that practice is left without any control whatsoever, and there are no means of ascertaining the qualifications of the persons who take it in charge. It is true, there may be some of my auditors ready to say, that midwifery is not singular in this defect, that recent examples, yet tingling in our ears, show that much is still wanting in other departments of medicine. With these topics, though I entirely agree, I will not at present meddle; my object this evening is to prove, that an important branch of our art is left in a condition inadequate in every respect, and that it is the duty of medical men to come forward and lend their aid towards remedying this defect. Five years have elapsed since, in this room and on this spot, I called the attention of the Westminster Medical Society to this very point. I then brought forward conclusive evidence of what I stated, and we came to the conclusion, that the state of medical police was low indeed. It was then stated and agreed to, that it would be desirable that a union should be formed of all those who felt unanimously on the subject; that such a union was likely to effect much good was admitted, and the Obstetric Society was accordingly instituted. Such was the state of midwifery five years ago, when the Society commenced to exist. My object is now to point out its present condition, to show how far, if at all, it is improved, and if improved, how far the amelioration is attributable to the efforts of the Obstetric Society.

The important bearings of this subject may be fairly deduced from three points:—In the first place, as I have already stated, the practice of midwifery involves in every instance the life of the mother and her offspring. In the second place, the condition of midwifery affects the future health of both individuals; and, thirdly, the question also is one on which the character of a highly respectable body of practitioners depends. To prove the two first positions, I need scarcely have recourse to the numerous actual examples of criminal malpractices arising from rashness and total want of education, for I do not intend the most remote imputation on the regular practitioners of the art. I am quite ready to admit, that in this country there have been, and are many, of the best practitioners in this department, and also that the opportunities of obtaining obstetric information are fully sufficient;

but to see that unfortunate events do occur in this department, resulting from the causes I have just alluded to, we have only to look to the public journals for the trials which are perpetually taking place before the tribunals of the country. On a former occasion, I detailed many cases of this kind, and further, I may remind my medical hearers of the facts which they sometimes learn in the secrecy of consultation with each other. I never, however, attempted to break the proper seal of confidential practice; God forbid, unhappily it was unnecessary to do so; for a sufficient number of cases are on public record to authorize the conclusion, that the life of the mother and child is too frequently, in many cases, rashly entrusted to the management of totally uneducated persons. We all know the case of a practitioner, whose name I need not mention, who tore from the patient's body the very parts which had just yielded the offspring; it happened in this very town, and the facts have been commented on by the ablest men. In Carlisle jail there is another person at this moment completing his term of six months' incarceration for obstetric malpractice, though certainly his case has not been sufficiently investigated, for fever supervened after delivery, an occurrence which might take place with the best accoucheur in existence, and in this respect his sentence affords a remarkable contrast to that on Mr. St. John Long for his first conviction. However, sir, these cases, and I might relate fifty more, are quite sufficient to prove, that in order to prevent these mischievous and fatal blunders, some legislative enactment should be provided. Again, sir, though it may providentially happen, that the female escape the dangers of the hour of travail, that she may not fall an instant victim to the recklessness and ignorance of her attendant, yet it does not follow that she shall remain free from ulterior injury. We, who are many years conversant with dispensary practice, know too well, that in regard to female practitioners in particular, than whom there does not exist a more ignorant, illiterate, ill-conducted class of people (*Hear*); with respect to these, we well know, that though their unhappy patients escape the fatal effects of their ill treatment, yet they do not escape the mutilations, the ruptures, the inevitable, irremediable lacerations; they do not avoid the injuries and deformities which so often render them for ever after unfit for the purposes of society. I need not further point out the cases recorded in different public journals of lacerated perineæ, of ulceration taking place in the urethra, in consequence of the head having been allowed to remain impacted for hours and days, till pressure on the arch of the pubis contused the parts,

and incurable ulceration ensued. I leave this, and come to consider, in the third place, how far our own respectability is concerned in the protection which I claim for the general practitioners, and to which they are unquestionably entitled. What becomes of their respectability (I include myself amongst them), when the newspapers teem with trials and with sentences—when investigations concerning wilfully-procured abortion, illegitimacy and infanticide questions, are put, and receive such disreputable answers, what becomes, I repeat, of our respectability, when such things as these go forth to the public? For these three reasons, sir, I conclude that it becomes our duty to take part in the efforts of individuals endeavouring to originate or promote measures for the procural of the legal protection which I have shown to be required. (*Hear, hear.*) The present state of the law is the most singular that can be imagined,—such, that had the efforts of the Society been seconded somewhat more strenuously, they would ere long have called forth such remonstrances from the whole body of the profession, that an end should have been put to this extraordinary and anomalous condition. We have three corporate bodies, shall I say happily, the Society will answer *in petto* to the question; we have the Royal Colleges of Physicians and Surgeons, and the worshipful Company of Apothecaries. These bodies are placed at the head of the medical police of London by virtue of their office; but what general law is there besides, to prevent the spreading of the most pernicious and fatal empiricism, to prevent a fruit-woman or a washer-woman from practising midwifery or any other branch of the medical profession? There is none, sir, such is the state of the law. Shall nothing be done to remedy the disgraceful defect? Let us look for a moment to the corporate bodies, and see what have they done, whether to prevent or promote this dangerous evil. I will begin with the College of Physicians, of whom, if possible, I wish to speak in terms of respect, but the way in which they remedy this defect, is by excluding from their list every obstetric practitioner. Their fellows must abjure it: their licentiates, whose skill in other respects has been proved by examination, are also subject to the same law. Next I turn to the College of Surgeons, and see what have they done to help us out of the difficulty: why they exclude the regular surgeon who dares to practise midwifery from being a member of their council or of the Court of Examiners, unless he previously abjures this filthy part of his profession. In the third place, I come to the worshipful, aye, I may truly say the worshipful Company of Apothecaries: they do not exclude, they do

not offer a bounty to their members not to practise midwifery; on the contrary, all that lay in their power to promote its adequate cultivation they have done, but, unfortunately, by the nature of the act which they have obtained, they have not acquired the power to examine candidates in this branch of medicine, so that even here the public has no security, as the qualification of the candidates cannot be ascertained. This, sir, is the state of the law and of the corporate bodies, a state which I have called anomalous, and which would seem incredible, if it were not too manifest to be denied. In other countries the case is very different, there is no distinction between the physician and surgeon who practise midwifery, and no man or woman is suffered to practise without having certificates of a certain quantity of education, and having passed a sufficient examination, and there are salutary penal laws by which this regulation is enforced. In France, in Italy, in many parts of Germany, there is no town or village in which there is not a practitioner, more frequently a female, who has not received at least a local education from a competent person, and a certificate of having passed an examination, and received permission to practise from a competent authority.

Having proved, I trust, that the political condition of midwifery in this metropolis was in a state at the commencement of the efforts of the Obstetric Society which called for prompt interference, I shall now state succinctly the progress of this Society which was formed in this room, and which, notwithstanding what has been jocularly written on the subject in one or two publications, will, I confidently believe, form a eulogistic feature in the medical history of this metropolis. This Society was not a new attempt; and when I mention that a similar effort was made in 1780 by men with whose names and works my hearers are or ought to be familiar, namely, Denman, Clarke, Sir W. Knighton, Dr. Ramsbotham, and others, it would be perceived that the present Society did not meet without a precedent at least. In 1825, circulars were forwarded to such practitioners as were known to practise midwifery in London, stating the intended formation of such a society. A numerous meeting accordingly took place, to which I submitted the proposed operations; this draught I have now before me, and from it it will appear, that one of the principal objects of the Society was to obtain a legal enactment on the subject of the unprotected condition of midwifery. As, in this country, it is perfectly impossible to obtain redress of any grievance without courting the good will of the heads of the profession, it was proposed and

carried that the three corporate bodies should be apprised of our intention, and requested to willingly, wilfully, and manfully assist in the promotion of the proposed object. Well, sir, letters passed and letters came, but no end would have been seen to the correspondence, had not an application been made to the minister for the home department, who willingly entered into the views of the Society, and through him we received letters from the several corporations, more meekly and courteously worded than it is possible they would have been if addressed to the Society, which one of these bodies had dared to libel in the most illiberal manner—a libel which it may be supposed some of us, who had the “gift of the gab,” would not be slow to answer, but that we had an excellent moderator, who repressed any demonstration of the kind. It is needless, sir, to state the bickerings, the bad epistolary correspondence, and the lapse of time, I will at once come to the point and state, that after all the letter-writing, the members of the Society found midwifery scouted by two of the corporate bodies, and admitted by the third, without the power of rendering that recognition of any utility, so that at the last meeting matters stood thus:—The College of Physicians admitted the necessity of a legal enactment, and proposed to receive an assessor to examine candidates on what they pleased to term the *manual* branch of the obstetric art. We have obtained from the College of Surgeons this much, that they require certificates of attendance on midwifery lectures, and from the Apothecaries’ Company, that they will examine if authorized by a rider to their act, and they have most handsomely added, which was as much as they were entitled to do, that they will henceforth require certificates of attendance on lectures, &c. &c. Lastly, the society has obtained from the secretary of the home department a declaration to the effect, that the want of a legislative enactment was utterly anomalous, that it was unknown to him before, and that, if the three corporate bodies would co-operate, he would endeavour to obviate the defect, one which struck him as amounting almost to an incredible absurdity.

This, sir, is the upshot and pith of all the Obstetric Society has been able to do in five years; you will say, perhaps, it is but little, but, in truth, it is comparatively a great deal. We at once grappled with the offer of the College of Physicians, and we took care to throw on them the whole of the serious responsibility of the matter, since they had at all taken it up. The minister was now tired of the affair, and appeared inclined to wash his hands of it all together, and with time the ministry was changed,

and we have not yet received even the semblance of a likelihood of the boon the College of Physicians promised to confer. With respect to the College of Surgeons, it appears perfectly unwilling to part with its old habits, but it has certainly done a little in requiring certificates of lectures. We have thanked the Apothecaries' Company for the zeal they have displayed, at the same time that we agree entirely with the expression they have conveyed to us of their feeling the absurdity of requiring a certificate on a branch on which they dare not ask a question. In conclusion I will only observe that the state of midwifery in the metropolis was pitiable before 1825, I believe it is piteous now; the part which the Obstetric Society took to do away with even the second adjective is manifest, though unfortunately it has not been successful. The Society still does not consider its labours at an end, though the pressing pursuits of several members, and the absence of Dr. Clarke, have interfered with its frequent meetings. I now bring the subject before the Society and the public; in doing so I know I may be exposed to the obloquy, out of doors, of some of my own branch of the profession. This day it has been stated in a periodical that I have been the author of "low trash" in vindicating my claims on a certain subject against those of a man who had actually done nothing upon it; but for these animadversions, sir, I care nothing, for I am conscious of the rectitude of my own assertions and intentions (*Hear, hear*). I address here persons perfectly prepared to understand the question, and I shall be happy to take the sense of this meeting upon the facts I have stated. I beg leave, sir, to propose the following resolutions:—

First,—That it is the opinion of the Westminster Medical Society, that the present state of the practice of midwifery, unprotected as it is by any legal enactment, calls for the interference of government.

Secondly,—That the endeavours of the Obstetric Society, with the view to rectify this defective state, is deserving of the approbation and support of the profession in general, and this society in particular.

(Dr. Granville sat down amidst general applause.)

Mr. BACOT bore testimony to the correctness of Dr. Granville's report of the liberal conduct of the Apothecaries' Company.

Dr. GREGORY wished to know if Dr. Granville could inform him of the proportion of malpraxis in medicine and surgery to that in midwifery; he also wished to know whether every practitioner on the continent was not liable to action for malpractice as well as the accoucheur.

Dr. GRANVILLE alluded to the insidious

character of the first inquiry, a similar one having occurred in one of the letters from the College of Surgeons. In reply he could say, that it was not for him to bring forward data on more than one subject; far be it from him to libel so pure a body as the College of Surgeons or Physicians; he spoke of the state of the continent from his personal knowledge of France, the north of Italy, Germany, Saxony, and Prussia. In Russia, too, the most exemplary punishment was inflicted on empirics of every kind, a salutary despotism which formed a happy contrast with the expenses, delays, and vexations, attendant on the prosecution and conviction of manslaughtering quacks in this country.

Dr. STEWART seconded Dr. Granville's motion.

Dr. BARRY said he would oppose the motion, on the grounds that we had already quite enough of partial monopolies and partial usurpations in the medical profession, of a science which should constitute an undivided whole. Suppose a certain class of able and scientific men, oculists for example, would come forward and contend that the structure of the eye was extremely delicate, that its physiology involved an extensive and deep knowledge of abstruse mathematical points and calculations, and that they should like to have a legal provision in their favour. Again, suppose a particular set of physicians wished to arrogate to themselves the peculiar faculty of discriminating pectoral disease by the stethoscope, and that they should implore the legislature to prevent those from interfering with such disease who were not conversant with the instrument, what would a minister say to such entreaties? He would rather wish to improve and unite the whole science, as in Paris, where there was a general *reunion* of every thing great and luminous in the profession; where separate examinations were held on every subject, and no student quitted one branch till he was master of its details. The division of labour might be urged in support of the motion; it is said that sixteen persons are required to make a pin, that might be, but he was not to be told that the eye, the uterus, or the ovaries, can be separated from the general physiology of animals. For these reasons he did not wonder at the College of Physicians throwing cold water on the proposition. The females of every other tribe of mammalia were able to get rid of their young themselves; such he believed was the case in the savage condition of man. There are difficult occasions to be sure, but the necessary knowledge for the treatment of these occasions was only to be obtained at a perfect school.

Dr. GRANVILLE regretted to trouble the

Society so often, but his reply to Dr. Barry should be very short; in fact, it was only necessary to state that the Obstetric Society had all along most emphatically disclaimed any intention of erecting themselves into a separate institution, they were ready to dissolve the moment the necessary protection was afforded. He agreed with Dr. Barry's wish for the general reunion of the several departments of medicine.

Dr. Granville's motion was supported by Dr. A. Thomson, who suggested the propriety of petitioning the new ministry on the subject. The College of Physicians, he believed, did not wish to run the risk of an investigation of their charter on the occasion. The motion was opposed by Dr. Gregory, as unprecedented in the Society. Dr. Granville replied that a similar proceeding was adopted with respect to the Anatomy bill.

Dr. Barry moved as an amendment, that the words, "as well as the profession at large," should be inserted after the "state of midwifery," in the first resolution.

The amendment having been negatived without opposition, Dr. Granville's resolutions were adopted, and the meeting separated. It was announced that Dr. Stewart would read a paper on cholera morbus at the next meeting.

*Monday, November 15th.*

A paper was read by Mr. J. B. Sedgwick, on the character of the celebrated good duke Humphrey, the son of Henry IV., and protector of England during the minority of his nephew Henry VI. A cast of the prince's skull, taken from the original in his tomb at St. Alban's, was laid upon the table; the author gave a brief outline of the life of the Protector, introducing the most prominent features of his character, and comparing them with his cerebral organisation. The whole head, corresponding with his mental energy, was much above the average size. The intellectual organs were exceedingly well developed. The organs of amateness, love of approbation, self-esteem, combativeness, destructiveness, secretiveness, and firmness, were all extremely large, particularly the three latter, which were developed to a degree which is, perhaps, seldom observed. The greatest proportionate size was at the posterior-superior, the posterior-lateral, and posterior parts.

John Harrison Black, L.L.D., was elected a corresponding member of the Society.

---

DR. BLICKE ON PUERPERAL FEVER AND  
PERITONEAL INFLAMMATION.

---

*To the Editor of THE LANCET.*

SIR,—My attention having been especially drawn to your report of the Medical Society discussion on Nov. 1st, I went thither last night with a view of pointing out to your reporter the error he had fallen into. He has made me say, "that the fetid discharge from the uterus in puerperal fever had never been noticed by authors;" whereas, on the contrary, one of the arguments I used in support of the hypothesis I maintain, was, that all the ancient authors agree in its being one of the symptoms present. He fell into this error, by Dr. Ryan's combating my opinion, that no author had considered it the cause of puerperal fever, and mentioning Dr. Denman as having done so, which, if correct, I certainly was not aware of. I have not been able to refer to Dr. Denman; but be this as it may, it does not militate against my view either way, but in the one would tend to confirm it. As your reporter has avowedly not understood the theory I professed, I shall esteem it as a favour if you will give this letter a place in your Journal. I can with sincerity say, that after more than ten years reflection and practising with this view, I am more than ever convinced of its truth; and the researches of our continental neighbours are

---

LONDON PHRENOLOGICAL SOCIETY.

---

*Monday, November 1st.*

THE Society resumed their meetings for the season this evening, EDWARD WRIGHT, M.D., President, in the Chair.

Dr. WRIGHT delivered an address, in which he reviewed the present state of phrenology in this country, and the valuable support which it now received from the exertions of Dr. Vimont, who, he informed the meeting, intended shortly to commence a course of lectures on the science.

Mr. HENRY DREW read a short account of the crimes of Dobie and Thomson, the Gilmerton carters (lately executed at Edinburgh, for murder and rape committed under the most aggravated circumstances), in illustration of casts of their heads, which he laid upon the table.

Dr. VIMONT communicated to the Society a proposal for the formation of a new phrenological bust, on a new and improved principle. Several skulls of animals from the East Indies were laid upon the table by C. R. Hyndman, Esq., who related several anecdotes of their various propensities, which fully confirmed the remarks previously made by the members on their organisation.

confirming it, though not ascribing the *post-mortem* facts they have elicited to the same cause; it must, however, be apparent to every one, that if my views be correct, the results will necessarily be what they describe.

I believe then, sir, that the cause of puerperal fever is this:—"That when the uterus, either from a diseased state prior to parturition, or that an unhealthy action is induced from a protracted or difficult labour, and fever is endemic (especially if of a typhoid character), the lining membrane of the uterus secretes a very acrid foetid fluid (analogous to that which takes place in the unimpregnated female), so much so as to diffuse itself through the room, nay, I might say, the whole house, and that the train of symptoms which follows, and which we denominate puerperal fever, are produced by the absorption of that fluid into the open-mouthed uterine vessels, which the detachment of the placenta has occasioned. It is remarkable that Hippocrates, in speaking of the *lochia*, says, "*Quibus ex partu prodeunt alba, his vero suppressis, cum febre aurditas et dolor acutus ad latus, fit, mente moventur et perniciose habent;*" and Galen says, "*Quum igitur hic sanguis vacuatus non fuerit a mulieris puerperii, aut uterum ipsum in phlegmonem attollit magnam, aut, ad superiorem aliquam sedem vectus, parti expienti proprium affectum, periculumque, affert; ad quam autem pervenerit, mox apparentia symptomata indicabunt, quomodo et nunc, tum thorax, tum caput, vitiosum sanguinem, ab utero sursum delatum, exceperint;*" and as I believe no one will call in question the talent for observation exhibited throughout the writings of these men, it is a striking practical fact illustrative of the view I take, though the pathology is not the same.

I have drawn up a comparative statement

of the symptoms occurring in peritoneal fever or inflammation and puerperal fever, and I have examined it with various authors, and find that for the most part they concur with the table I present below. If we can once agree on this point, it is probable the treatment of this formidable disease might become uniform; it is impossible to peruse the authors who have latterly written on this subject, not to be struck with the discrepancy of treatment recommended; but looking narrowly for the cause, it is evident peritoneal fever or inflammation, and puerperal fever, are invariably blended together; I might mention Goose particularly.

I beg also to add my remarks about medical treatment referred to the active remedies, bleeding, mercury, &c. I think the exhibition of antimony, cold lotion to the head, fomentations to the abdomen and vagina, opiate glysters, &c., are of the utmost importance; and that if a parturient woman be watched every twelve hours, this disease will always be tractable with this treatment, while, on the other hand, by a delay of twelve or twenty-four hours, death will be inevitable.

I ought to apologize for occupying so large a space in your Journal, but the moral importance of this subject, as well as the professional, is so interwoven with the interest of society, and vanity urging me, as it usually does all men, that any particular theory of their own is of the utmost value, I hope I shall stand excused, even should I hereafter be found to be incorrect. The result of my practice bears me out, never having lost a parturient woman.

I am, Sir,

Your obedient servant,

W. F. BLICKS.

Walthamstow, Nov. 9. 1830.

### *Peritoneal Fever or Inflammation.*

*Period of its commencement.*—May commence at any period after parturition to the end of the fourth week, but usually begins on the second or third day, but whatever the period, the pulse has been frequent, small, and wiry, from the parturition.

*Preceded by vomiting or sickness, rigors or shivering.*

*Abdomen.*—Great general pain over the abdomen, with tension, the latter rapidly increasing.

*Pulse* frequent, usually firm, sharp, and wiry, in which state it continues.

### *Puerperal Fever.*

*Period of its commencement.*—May commence as late as the fifth day, but never later; usually in twelve, twenty-four, or thirty-six hours, rarely exceeding the latter time, but whatever the period be, the pulse will be found, if accurately watched, to have diminished in frequency and fullness after the parturition.

*Preceded by violent pain in the head, anxiety of countenance, great dejection of spirits, extreme languor, a loose, soft, flabby, muscular fibre, shivering, and occasional nausea.*

*Abdomen.*—Slight circumscribed tenderness of the abdomen, with a general fullness, the former most rapidly increasing.

*Pulse* rapid and full, but in a few hours, as its frequency increases, becomes weak and easily compressed.

*Tongue* clean, or white, and dry, with thirst.

*Skin* hot.

*Lochia* and *milk* are obstructed.

*Sleep*.—Is not refreshed by it, though it takes place, and always assigns as a reason she cannot turn in bed without pain.

*Countenance* alternates, but is usually flushed; eyes and lips natural, or, if otherwise, redder than usual.

*Respiration* difficult, with pain, and occasionally cough, with violent pain.

*Bowels* are either costive, or violently purged, with considerable flatulence, which is voided upwards and downwards with violent pain.

*Urine* scanty, but for the most part natural, and voided without pain, or very trifling.

*Breath* natural, but inclined to be sour.

*Extremities* cold.

*Tongue* clean, pale, sometimes white, but moist, without thirst, though drinks two or three mouths-full whenever it is offered.

*Skin* not hot, but inclined to be clammy.

*Lochia* and *milk* are suppressed with an extremely foetid, cadaverous discharge from the uterus, which, in a few hours, impregnated the whole room, even the house.

*Sleep*.—Has little or no sleep; either tosses about in bed, or lies listless, never asking about her child; or if she does sleep, awakes in a fright, and generally with a tendency to delirium.

*Countenance* pale and ghastly, eyes listless, cornea, canthi, and lips, white, in short a death-like appearance is presented, and is convinced of her approaching death.

*Respiration* said to be difficult by the patient, but takes a full inspiration without pain or coughing.

*Bowels* are always rather loose, with dark, foetid, cadaverous, frothy discharges, and it is remarkable that on each motion the patient expresses herself relieved, an admission never made at any other time in this formidable disease.

*Urine* dark-coloured, or diminished, or no ammoniacal smell, deposits a brown sediment, is voided often though scanty, and most generally with pain, occasionally not mentioning it, though it is known to be taking place from the evinced pain.

*Breath* faint and cadaverous.

*Extremities* natural heat, occasionally colder.

#### CASES OF

#### ARM-PRESENTATION AND EVOLUTION.

By G. COOPER, Esq., Surgeon, Brentford.

To the Editor of THE LANCET.

SIR,—In fourteen years obstetric practice, many cases of arm-presentation have of course occurred, in all of which I have been able to turn with three exceptions; and on one of those I need not dwell, it having been a twin-case. The presentation of the first child was natural; but from the moment the membranes broke with the second, and the arm came down, the pains were incessant, and in spite of every effort to turn, the ribs protruded, and the child was thus thrust into the world doubled-up as it were. I proceed, therefore, to give a short history of two cases of arm-presentation, in which I found it impossible manually to turn.

If you consider them of sufficient practical importance to merit a place in THE LANCET, they are much at your service, and I send them without comment.

I am, Sir, your very obedient Servant,

GEO. COOPER.

Nov. 24, 1830.

CASE 1.—Is that of Uram Howard, which occurred in November 1818. The patient was then forty-five years old, and was in labour with her fifteenth child. Introductory pains commenced on Saturday, and Mrs. Brown, a midwife, was in attendance. The pains continued to return at intervals until Tuesday evening, when, as the labour proceeded but slowly, and the patient's sensations were peculiar, the midwife requested that I might be sent for. The impression on the patient's mind was, that she should have twins. Upon examination I found that the membranes were not broken. On Wednesday the midwife again sent to me, and now I discovered the arm presenting, and so firmly wedged in, that the child could not be turned. I remained with Mrs. Howard until two o'clock on the morning of Thursday, when all attempts at turning were perfectly useless, the child being so firmly embraced by the uterus, that the hand could not be introduced in utero, without the utmost risk of lacerating the organ. The pains had been strong and frequent, they now began to diminish both in frequency and power; but still, even in the interval from pain, the uterus embraced the child so

as to prevent the introduction of the hand. Her countenance became anxious, she was restless, threw herself about with a degree of involuntary jactitation; her nervous system was irritable, and although she had had fourteen children previously, and had never evinced any apprehension, she now expressed the strongest fear that she should die.

Reflecting upon the case physiologically, I felt convinced, that if I could only produce a *relaxed state of the uterus*, no difficulty could exist in delivering this woman; and with the view of producing this relaxation, I took twelve ounces of blood from the arm, gave her tinct. opii gtt. i., and put her into a warm bath at 98 degrees, in which she remained three quarters of an hour.

All pain went off in the bath, and syncope was nearly induced, but she never quite fainted; she was put into bed again, and expressed herself as feeling very comfortably. The pulse, which before the employment of these means was quick and irritable, now became less frequent, soft, and round: she asked for gruel, and to be allowed to remain quiet.

Having been up that night and the preceding, I laid down, and requested the midwife to call me directly pain came on, or when either she or the patient required my assistance.

No pain, however, did come on; the uterus became *relaxed*, while the patient was dozing; *spontaneous evolution* took place; and at four o'clock, two hours after she had been bled, put into the warm bath, and given the opium, the *feet came down* instead of the *arm*; and with two or three continuous *slight* pains, the child followed without the least difficulty, even before I got into the room—a still-born male child at the full period. The mother did quite well, and is now living.

CASE 2.—On the 18th March, 1829, I was requested by a midwife in this town to see Mrs. Ann Lee, aged 24, who was in labour with her third child. She had been in labour six-and-thirty hours. How long the membranes had given way I could not ascertain, but I found *both arms* presenting, which were much swollen, and must have been firmly impacted many hours.

The woman's sufferings were unusually severe; her pains were very strong; and in the intervals, every attempt to turn was quite unavailing. The uterus seemed spasmodically contracted upon the child; for, not only on examination *per vaginam*, but upon feeling it through the abdominal parietes, it never appeared to relax in the least when the pains went off. Had I attempted to turn *per vim*, so rigidly con-

tracted was the uterus, that the consequences, I conceive; must have been fatal.

In this case as in the former, the practical object seemed to be, to alter the position of the child by *relaxing the state of the uterus*; and with that view, I pursued very nearly the same means as those I adopted in Mrs. Howard's case, and with equal success.

I put this patient also into a warm bath; directly she was in the water, I took twelve ounces of blood from the arm, and gave her 60 drops of laudanum. I waited a quarter of an hour, and no degree of faintness was induced; I therefore loosened the tape, and took twelve ounces more blood. She now complained of feeling rather faint, and I tied up the arm.

From the moment of going into the bath, the pain ceased. When she had been in about twenty minutes, immediately after the second bleeding, syncope was approaching; I therefore directed the attendants to take her out of the bath, and from motives of delicacy I just stepped into an adjoining room, during her removal to the bed; but I was directly called back, and with a faint voice she said, "Sir, the child is being born;" and true enough, the means employed had produced a *relaxation of the muscular structure of the uterus*. *Spontaneous evolution* had taken place, if that can be called spontaneous which was induced by art, the *arms had receded*, and the *head* had descended, and the child was born without the patient being conscious that she had pain. The child was a still-born male, at the full period. The mother did extremely well, and recovered without one bad symptom, and has lately been confined again.

#### LATE INQUEST AT HAMPTON.

#### To the Editor of THE LANCET.

SIR,—As some of my friends have imputed to me the alleged want of professional skill exhibited by the Hampton practitioner, I shall feel obliged by your informing them that my place of abode is *Isleworth*, and not *Hampton*. I should not have troubled you with this letter, had not various reports been circulated in different quarters, highly prejudicial to my professional character and reputation. Although I bear the same name, I am in no way connected, either by family or otherwise, with the gentleman whose obstetric conduct was the subject of inquiry at the late inquest at Hampton; and I must add, that I neither did nor do approve of his treatment of the case, or the bungling and lame defence of his friends and witnesses.

I remain, Sir,

Your obedient humble Servant,  
W. S. BOWEN, M. R. C. S.

Isleworth, Nov. 12, 1830.

# THE LANCET.

*London, Saturday, November 27, 1830.*

It were idle to discuss the defects in the existing medical corporations, unless with a view to their general improvement. If the construction of the Colleges of Physicians and Surgeons and the Company of Apothecaries be suited to the temper, the knowledge, and the wants, of the present advanced period of society,—let them stand as they are, undisturbed, unmolested. On the contrary, if these institutions be governed upon principles the most odious, narrow-minded, and illiberal,—calculated to create constant dissensions, distract the attention of professional men from their scientific pursuits, and to retard the progress of that knowledge which they were founded to promote, then it behoves every well-directed mind to exert the whole of its energies and faculties to effect their amelioration or destruction. In a “certain house” we hear it announced, that “restoration,” not “revolution,” is the order of the day; a sentiment promulgated curiously enough by men, whose measures for the last thirty years have had such a revolutionary tendency, that England, now almost from one end to the other, teems with incendiaries. We shall not, in this place, pronounce any opinion upon the rationality or the propriety of the term “restoration,” when it is applied to the political institutions of this country; but we hesitate not to say, that it is calculated to do little more than elicit a smile, if such an emendatory term be applied to the medical corporations founded by HENRY VIII. and JAMES I. Whenever those persons, who have a little more foresight than their neighbours, attempt any great work of improvement, the corrupt leaven of some of our “ancient” and venerable institutions is sure to rise into terrific appearances, to the sad affright of the feeble-minded of both sexes. “Revo-

lution” is ever the watch-word of corruptionists. But what great improvement was ever effected without more or less of revolution? The incorporation of the barbers with the surgeons was a sad revolution for the barbers; and doubtless the subsequent separation of the surgeons from the barbers was a fortunate revolution for the surgeons. The establishment of the College of Physicians by HENRY VIII. was a complete revolution in medical policy. The decision of the House of Lords in the case of ROSE and SEARLE, was another revolution; for, until that period, no person in London, if he were not a Fellow, or a Licentiate of the College of Physicians, could visit and prescribe, without being amenable to the consequences of a penal statute. The passing of the Apothecaries Act, so lately as 1815, was another revolutionary measure. For if we are to take the decisions of the judges, as the indisputable law of the land, that act has wrested from the members of the College of Surgeons nine-tenths of their rights; moreover, there was the less ground for passing that Act, because in the Charter of the College of Physicians and Surgeons there were powers sufficient, had they been put in force, to have protected the public from the practices of incompetent medical pretenders. What a farce is it, therefore, to refrain from measures of improvement, lest they should lead to “revolution!” We contend, then, fearlessly, that unless the present system of medical government be radically and entirely changed, the members must continue in a station far below that which they are entitled to hold by their talents and their usefulness, and that the public will never derive those great advantages from the cultivation of the science of medicine which it has a just right to expect. The first object of every wise government has always been to secure the health of the people, without which there is no strength; for, although “knowledge is power,” it would be

of a very harmless kind, in a national sense, if it had not for the ready instruments of the will, well-formed bone and vigorous muscle. In all ages, the professors of the healing art have been revered, alike by the learned and the vulgar; MACHAON and PODILERIUS were even deified. Nothing but apathy or ignorance could induce any government to neglect the interests of the professors of such a science as that of medicine, considering the incalculable advantages which they are capable of conferring upon the community. The manner in which medicine has been neglected in this country, speaks little for the wisdom of our ancestors. In truth it cannot be denied that, even of late years, parliament has, on every occasion, evinced a most culpable negligence in all matters concerning the welfare of the medical profession. Every medical subject has been discussed with impatience; with that sort of anxiety which denoted that even *thinking* on such a matter was not unaccompanied with mental suffering. Who can have forgotten the miserable exhibition in the House of Commons, when the late Anatomy Bill was brought forward? With the exception of Mr. HUME, Mr. WARBURTON, and two or three other members, it would appear that the honourable gentlemen had taken pains to signalize themselves by uttering the most contemptible common-place trash that ever was heard in a rational assembly. The bill itself was avowedly framed to *prevent* a repetition of the crimes that were committed at Edinburgh by BURK and his hellish associates. The circumstance that led to those crimes, was the readiness with which cash could be obtained for the murdered bodies. But in the *preventive* anatomy bill there was no mention of any penalty, not even of the smallest fine, or of the shortest imprisonment, to be inflicted upon persons who should be detected in carrying on the barbarous traffic in human flesh. Thus it has been with every medical question, in the House and out of

the House. The royal colleges having failed to discharge their duty to the public, they have been actively engaged in smothering inquiry, by rendering intricate and obscure all those subjects in which they have been interested, all those abuses by the existence of which they have acquired their ill-gotten wealth.

"Restoration," then, is not what will satisfy the members of the profession in the present day. There must be a revolution in medical government, or the change cannot, will not, satisfy, the just demands either of the profession or of the public. Is it likely that the charters which were framed three hundred years since, are suited to the intelligence and demands of the present day? Besides, in most of the old charters, the petitioners included all who were to be affected by it, or whose interests were to be advanced; but in the modern charters, the commonalties have been carefully excluded from participating in corporate privileges. Thus, in the charter which was granted to the College in Lincoln's Inn Fields by his Majesty GEORGE III., the petitioners and their successors were permitted to fill up all the vacancies in their own body, thus constituting the Council a self-perpetuating engine, in controlling the movements of which the commonalty were to have no share. The members, therefore, form no part of the body corporate. Strange members, indeed! It is a body without head, *heart*, or extremities. The influence of these corporations overminds not strengthened by fixed liberal principles, is exceedingly great, and few men so far resist the temptations to which they are subjected within the walls of iniquity, as to retain a character for independence and integrity, if they have the misfortune to accept office with so excellent a testimonial of worth. The impartial and honest mind is assailed by every species of bribery. The allurements of gold, and the fascinations of the sumptuous feast, are ever ready for its ensnarement. Mr. CARMICHAEL of

the Dublin College, after having lent, for too many years, the reputation of his name to the tyrannous misdeeds of his colleagues, has, at last, manfully and honourably resigned his seat, flung off the robes of office, and left a corporation of which he could not longer have continued an acting member, without utter ruin to his reputation. Until the recent manœuvres of his unworthy coadjutors, he was not, probably, aware of the pernicious practices of the College to which he belonged; but the late attempt to compel all candidates for the diploma to undergo the ordeal of an apprenticeship to those who, while they signed the indentures with one hand, were pocketing the fees with the other, so completely unmasked the flimsy pretensions to public spirit, of those who were enacting such base regulations, that Mr. CARMICHAEL became fully sensible of the degrading society in which he stood, and instantly resolved, by one honourable step, to quit it for ever. We have not yet seen the new Charter of the Irish College of Surgeons, but it cannot be worse than that which was framed for the government of the College in Lincoln's Inn Fields,—an institution which still exists, to the shame and disgrace of the profession. We are utterly at a loss to understand why there should be such variations in the Charters of the London, Dublin, and Scotch Colleges. We cannot perceive that any advantages result from the institution of such dissimilar laws for the government of societies of gentlemen, all occupied in the same pursuit,—the cultivation of the science of medicine. At any rate, if we are to have one comprehensive law for the government of the whole profession, the Charter of the London College of Surgeons must not be taken for the model. It originated with the chavers; it had, truly, a barbarous origin; but its enactments are not more contemptible, than are the feelings and the principles of the individuals by whom it is supported. In our next number we shall compress into as short a space as possible,

some account of the charters which have been granted from time to time for the government of this College. The reader will find it well worthy of his attention; for he must not forget that it is our object to show, First,—That medical enactments have never been founded upon a knowledge of the wants, the utility, or the respectability, of the profession; and, Secondly, That we should apply our best energies to establish a college, in which all branches of the profession may meet as one united brotherhood.

---

JOHN LONG, THE SLAUGHTERER.

WE are under the necessity of announcing that this individual has not yet been taken into custody, though we have been given to understand, from undoubted authority, that he has been seen walking in Regent Street within these few days. In whose hands is the warrant placed, and how is it that the magistrates do not interfere? If an humble individual, unassociated with marquesses and lords, were under the charge of manslaughter for the second time, upon the verdict of a coroner's jury, he would not be allowed to walk the streets with impunity. The voice of justice is loud in its demand upon Captain LLOYD to show neither mercy nor favour to the slayer of his wife. LONG, we understand, has retained Messrs. ALLEY and PHILLIPS, the counsel who were opposed to him in the late prosecution. We are told that the fellow has written to Mr. WONTNER, the governor of Newgate, to know if he can be accommodated with the STATE APARTMENTS again! If it be possible, the impudence of the wretch is an overmatch for his ignorance.

---

MR. CHARLES BELL, late professor of Physiology and Clinical Surgery in the London University, no longer fills any chair in that institution.

SUMMARY OF  
THE WOUNDED AT PARIS.

IN our notice <sup>last week</sup> of M<sup>me</sup>nière's History of the *Hôtel Dieu*, during and after the late revolution, we were compelled to omit the following summary of the wounded who were admitted at the Parisian Hospitals, but as it is a report of some interest we now give it. We have already noticed the particulars furnished from the above hospital, but repeat it here in order to make the list complete.

At the *Hôtel Dieu* there were admitted 390 wounded, of whom 122 died, 40 of them during the first three days after their admission; the wounds were in general very severe; more than a hundred fractures were observed, in thirty-four cases of which amputation was performed.

At the *Charité* 165 were admitted, of whom 50 died; of fifteen cases where amputation was performed, seven only terminated successfully.

At *St. Louis*, of 152, 39 died; six or seven secondary amputations were performed, but in one case only with success.

At the *Pitié*, of 108 wounded, not more than nine died; a result which is far more favourable than has been obtained anywhere else, except, we believe, at the *Gros Caillou*; it is, however, in some degree accounted for by the circumstances, that amongst the 108 wounded there were only six fractures, and that only two amputations were performed; besides this, a great many wounded were taken immediately from the field of battle to the *Hôtel Dieu*, where their wounds having been dressed, those who were able to be conveyed to more distant hospitals were immediately sent away, and of these about sixty were admitted at the *Pitié*.

At the *Hopital Beaujon* 89 were received, 31 of whom died; this mortality is in some degree explained by the very murderous fighting which took place in the immediate neighbourhood of this hospital during the retreat of the troops. Owing to this circumstance twelve of the wounded died immediately after their admission, and in the above eighty-nine cases thirteen amputations were performed.

The *Hopital Necker* took in 37 wounded, five of whom died immediately after their entrance, and eight in the course of the first twenty-four hours. Three amputations only were performed.

At the *Incurables Femmes de la Rue de Seures* 34 were admitted, four of whom died during the first forty-eight hours, one of whom was young Vannau of the Polytechnic School.

The *Cloître Sainte Marie* and the large hall of the court of commercial law (salle d'audience de l'ancien tribunal de commerce) received 127 wounded, but 75 were soon removed. Of the 52 remaining 14 have died, all of them before the 4th of August; one amputation only was performed.

The *Hospice d'Enghien* took in 10, all of whom recovered.

At the *Hopital Carlin* nine were admitted; and six others were distributed amongst the *Hospice du Larochefoucault*, *Enfans Malades*, etc.

The total number of wounded admitted at the civil hospitals at Paris amounts accordingly to 1200, of whom 304 died.

The information regarding the "*Ambulances*," which were immediately established in different quarters of the town, are of course rather incomplete; the following may, however, be considered as coming very near the truth.

At an "ambulance" near the *Rue des Pyramides*, 170 wounded were received, 130 of whom were subsequently sent to the hospitals; the wounds were comparatively slight, and no amputation was performed.

At the "*Passage de Saumon*" 90 were received, most of them only to have their wounds dressed; none of them died, though some wounds were rather of a dangerous kind.

The Exchange also became an asylum for the wounded, 75 of whom were admitted there; 48 were subsequently sent to the hospitals; of the 27 remaining, two with wounds of joints are in a hopeless state, the others are recovered.

In addition to these, about 400 wounded were temporarily admitted at the *Hôtel Dieu*, as we mentioned in our account last week, who, after their wounds had been dressed, were conveyed home, or even returned to the field of battle; and lastly, a great number of wounded were attended at home. So that adding their average number to that of the admissions at the civil hospitals and the ambulances, the whole number of the wounded would amount to about 2000.

The exact number admitted at the military hospitals is not known; but it seems that it did not exceed 500. The mortality at the military hospitals is reported to have been extremely small, which seems to be dependent on two causes; first, because the citizens were, especially at the commencement, badly armed, and inflicted but slight wounds; and secondly, because of the soldiers previously admitted at the civil hospitals, all those who were able to be conveyed were, from the 10th of August, sent to the military hospitals, the relative mortality of which must, by this circumstance, have accordingly been much lessened.

The number of killed on the field of battle amounts to about 890, of whom 125 were exposed at the Morgue, and the rest were buried; the total ascertained number of the killed amounts consequently to 700, and that of the "mis hors de combat," to about 3000.

From these data, it appears that the reports circulated immediately after the "three days," were much exaggerated; we fear, however, that when the above calculations are completed by the authorities, the three days will prove to have been much more disastrous than would appear from M. Ménière's statement; the number of the wounded who were treated at home is evidently too small; and in that of the killed, those whose bodies were thrown into the Seine, etc., do not seem to be included.

#### DRACUNCULUS OR GUINEA WORM.

In a former number of *THE LANCET* we gave a short account of a medical school at Abou-Zabel in the neighbourhood of Cairo, under the superintendence of a French physician, M. Clot, who has lately published a report on the institution, and the hospital attached to it. We hope soon to lay an extract of it before our readers, and shall meanwhile give some of the cases of dracunculus observed by M. Clot, and reported in the *Lancette Française*.

**CASE 1.** A negro of Darfur, *ætat.* 25, a soldier in the Egyptian army, was admitted on the 2nd of April, 1825, with a painful swelling of the scrotum, accompanied by fever; he was bled and an emollient poultice was placed round the scrotum; after about ten days an abscess had formed on the right side of the scrotum, which having been opened and a small quantity of purulent serum evacuated, a dracunculus showed itself at the wound, four inches of it were immediately extracted, and rolled over a piece of plaster; the extraction was repeated daily, so that on the 18th the whole worm, twenty-three inches in length, was extracted.

**CASE 2.** A negro boy was admitted on the 12th of May, 1825, with pyalism and a painful tumour at the apex of the tongue, the gums were swelled and bleeding. After a careful examination of the mouth a small fluctuating tumour was discovered near the frænum lingual, which was opened, and discharged, with a small quantity of purulent serum, part of a dracunculus, which was seized, and without any difficulty extracted, it was four inches in length. After a few days under the use of an emollient gargle, the patient was perfectly cured.

**CASE 3.**—A negro, twenty years of age, came to the hospital on the 8th of June,

1825, with a swelling and violent pain in the penis; it was at first taken for a syphilitic affection, but on closer examination a dracunculus was found encircling the penis; it very much resembled an inflamed vein, and caused much pain along the spermatic chord. Under the use of an emollient poultice, a vesicle formed at the parts behind the glans, opened on the 18th, and discharged about half an inch of a dracunculus which was fixed to some sticking-plaster, and slowly extracted; this caused, however, such violent pain, that the extraction was not completed before the 1st of July, although the whole length of the worm did not exceed five inches and a half.

**CASE 4.**—W., an Arab soldier, thirty years of age, was admitted on the 20th Oct. with inflammatory swelling of the left leg, which was very painful, &c. He was bled, and as M. Clot suspected, a dracunculus was perceived, though he was unable to trace it; the leg was covered with a poultice, and after ten days a vesicle formed at the outer angle was opened, and from it part of the dracunculus extracted and fixed to a piece of sticking-plaster; on the 5th of November it unfortunately broke; the purulent discharge however continued, and another abscess soon formed about four inches above the first, from which another portion of the worm was extracted. On the 23d the extraction seemed to be complete, the inflammation in the leg had also subsided, and the patient was discharged well on the 15th of December. On the 23d, however, he returned with pain in the ham, from which, within six days, ten inches of the worm were extracted. From this time the patient remained perfectly well.

M. Clot says it was impossible for him to decide whether the three pieces belonged to one worm only, or formed three distinct worms.

In the year 1822, M. Dussap, the chief medical officer of the Egyptian army, treated at the hospital of Soutan about 400 individuals affected with dracunculus, and at last caught the disease himself on the left hand; the first symptoms, he says, were a painful itching on the dorsal surface; he is of opinion that the frequency of dracunculus dates only from the above year, and was communicated to the Arabs and Egyptians by negroes. He believes in the immediate contagion of the worm, and quotes as a proof his frequent observation of dogs, who became affected with it after having eaten the poultices from patients with dracunculus.

**CASE 5.**—M. Dot, French teacher in the service of the Pacha, became affected with dracunculus in 1824; it began with a small vesicle over the metatarsal bones of the first and second toe of the right foot; it was sur-

rounded by an intense redness, and caused a very painful itching. After a fortnight, the pain became so violent as to render M. Dot incapable of any exertion; the vesicle having broken, the worm became visible, and seven inches of it were extracted with excruciating pain, but without being followed by any diminution of the symptoms. After a short time another vesicle formed over the outer ankle; from this a dracunculus eleven inches in length was extracted, and under the application of poultices, two more abscesses opened over the tendo Achillis, from which two worms were drawn out, the one two, the other of twenty-four inches in length. The inflammation of the leg, however, continued, and became even alarming; the swelling increased, the pain was very violent, and accompanied by intense fever, so that it was feared amputation would become necessary. A large number of deep incisions were made at the places from where the worms issued, and a quantity of bloody and purulent matter was evacuated with the remains of worms, the greater portion of which had been partly extracted. Of the two first worms, about four inches only were found to have been left, of the third seven, and of the fourth two. After this time M. Dot completely recovered.

In 1820, Mehmud Ali sent an expedition to Cordofan, where M. Marduchi, physician to the head officer of the troops, remained for three years. During the first two years, no case of dracunculus was observed; in the course of the third, however, after very heavy rain, nearly the fourth part of the troops became affected with it, and M. Marduchi himself got it in twenty-eight different places, which, according to the statement of the natives, is unprecedented. In a letter to M. Clot he states, that before the beginning of the disease he was affected with an unpleasant itching and slight swelling of the legs, on which, after about twenty days, small and very painful tumours, like far-nacles, formed, which, under the use of poultices, opened, and gave issue to parts of worms which were fixed and gradually extracted; four, however, broke, and this accident was followed by excruciating pain and such intense inflammation, that twice gangrene was produced, and it was not till after four months that the wounds healed. All the worms were in the lower extremities except one, which formed over the coccyx.

ALDERSGATE-STREET SCHOOL.—MR. KING.

To the Editor of THE LANCET.

SIR,—By a breach,—not indeed of any expressed compact,—but of the far more

powerful bond of an honourable understanding, the proceedings of a body of pupils at Aldersgate School, which they had been permitted to consider as of a purely domestic character, have been rashly exposed to the public. The following letter, purporting to furnish a statement of these proceedings, appeared in the last number of the Medical Gazette.

*"Aldersgate-Street School.—Mr. King.*

*"To the Editor of the London Medical Gazette.—Sir, As an interested party in the following proceedings have expressed their intention of addressing a most impartial statement to the editor of a publication ever recognised by its patronage of falsehood and vituperation; I should be greatly favoured by the following statement appearing in your Gazette for Saturday, Nov. 20th instant.*

*"I remain, Sir,*

*"A FRIEND TO CANDOUR AND TRUTH.*

*"Notice.—A General Meeting of the Pupils of the Medical School, Aldersgate Street, will take place in the Anatomical Theatre, Thursday, 11th November, for the purpose of presenting their late teacher, T. King, Esq., with some mark of their respect.*

*C. BLAIR, Secretary.'*

*"Agreeably to this notice, a meeting took place at the time appointed, Mr. Ryley in the chair. A statement of the purport of the meeting by Mr. Blair having been made, the object, *volens volens*, was attempted to be carried. A spirited discussion was the consequence. The new pupils of the School, ignorant upon what principles they were requested to forward an intention in which they were perfectly uninterested, declared themselves adverse. The following resolution was moved by Mr. Quinn, and carried unanimously by them:—*

*"Resolution.—That, as a general body, the pupils of the Aldersgate Street Medical School do not consider it expedient to present such testimony."*

The real history, of which this letter contains a very clumsy misstatement, may be told in a few words. Some pupils of the School,—to whom I am far from imputing it as a cause of reproach that their discretion appears to have been no match for their generosity,—convened a meeting of the whole body, for the purpose of presenting their late teacher, T. King, Esq., with some mark of their respect. In the terms of their advertisement, the projectors of the meeting confounded two very distinct classes of pupils—those to whom Mr. King had been a teacher, and those to whom Mr. King was an absolute stranger. When the meeting assembled, I took an early opportunity of dwelling on this fundamental and obvious

error, and I strove to satisfy my fellow-pupils, who had not had the advantage of Mr. King's instructions, that the original resolution, if they agreed to it, would embody not only an untruth, but a downright absurdity. At what rate, I asked, did we value our own feelings—at what rate would Mr. King value the expression of those feelings, if they were to be carried in the shape of a token of gratitude for favours which we never received—for personal civilities from one in whose presence we never had the happiness to stand? A mark of kindness to Mr. King from those who do not know him, can only deteriorate, when it is combined with a testimony of respect from those who do.

Such were the natural considerations to which I called the attention of my fellow-pupils, and I have no wish to conceal that I felt a repugnance to concur in any demonstration of partiality (particularly remembering the time and the circumstances under which it was solicited) to a gentleman who accidentally stood in the relation of predecessor to Mr. Quain, lest the world should suspect that our estimation of the latter gentleman wanted any-thing of being commensurate with his high character and accomplishments. But we urged these considerations partly in vain, and we were forced to a measure which was only objectionable, as it is usually the expedient of hostility—an hostility not certainly felt on this occasion. An amendment was framed on the moment, and although it was hastily written on the railing of the theatre where we assembled, it fully describes the feelings and intentions of those who supported it.

"That this meeting, constituted of the general body of the pupils of the Aldersgate School, and convened for the purpose of presenting their late teacher, T. King, Esq., with some mark of their respect, consider it inexpedient to *entertain* the proposition."

The amendment, I need scarcely say, was carried. The distinction, you will observe, between declining to "entertain" a proposition; and refusing to grant what that proposition requires, becomes the whole point of importance in this case, and should satisfy any person that the principle of it was left untouched.

I should perhaps have been contented with the simple correction of the misstatements which the above letter contains, were it not that the author, in his anonymous character, demands a few words. A paper has been signed within these few days at our School, protesting against the letter, disclaiming all knowledge of its contents previously to its publication, and especially disavowing any participation in the spirit, the taste, or temper of the writer. This declaration bears the signatures of a large body

of the pupils, including, as far as can be ascertained, *the whole of the pupils who voted for the amendment*, so that I am justified in concluding, that the character of friendship to the new pupils which the writer puts on, is an imposture assumed for the occasion, and intended to facilitate some sinister design. The strict concealment in which his name has been kept since the publication, in defiance of every legitimate attempt to discover it, confirms the suspicion that his purpose was not a good one. I appealed to the justice of the editor of the *Medical Gazette*, who declined to state the name of his correspondent, although it could be proved that the writer had forfeited all claim to the protection which his obscurity affords him.

In conclusion I beg to say, that for one, I shall ever oppose that system, of which the present is a favourable example, of obtruding upon the public attention names and transactions which have no adequate claim to such notice. I deem it to be a calamity of no ordinary mischief, that a set of school-boys in a corner of the city cannot, in the intermission of their tasks, enter into familiar counsel with one another for the insignificant purposes of the moment, without being puffed into public characters, and their conversations swelled out into the importance of a debate. Above all, I lament that there should exist, amongst the journals of the time, a refuge to which anonymous malice and dissembling hostility may resort with success. It is a pity that youth should be encouraged to put off that ingenuousness which is its comeliest attribute, and that in shooting against the blameless arrows of its gratuitous spite, it can reckon upon a safe measure of protection and indemnity.

I am, Sir, your obedient servant,

THE PUPIL WHO MOVED THE AMENDMENT AT THE ABOVE MEETING.

Nov. 24th, 1830.

---

POWER OF THE LONDON COLLEGE OF PHYSICIANS TO SUPPRESS QUACKERY.

To the Editor of THE LANCET.

SIR,—I was much amused with the concluding part of Dr. Elliotson's clinical lecture in your Number 376, and desire your early insertion of the following observations upon it. The Doctor asserts, "that quackery may flourish; that the most ignorant may practise in spite of the Royal College of Physicians, and the Royal College of Surgeons, and the worshipful Company of Apothecaries; that no one can touch such persons: no one can prevent their proceedings; for of course those great bodies would do their duty to the public, if they had the power to interfere."

This, sir, is an admission from a fellow of the Royal College of Physicians which I did not expect. Is it really possible that this term-trotting Cantabrian, this renegade from Edinburgh, can be so little acquainted with the constitution of his Royal College as not to know, that its charter of incorporation contains the most ample directions for the suppression of quackery. It appears to me, that the royal founder established the College more for the extinction of empiricism, than for all other purposes. The celebrated charter begins thus:—

“Henry, by the grace of God, King of England and France, and Lord of Ireland, to all to whom these presents shall come greeting. Inasmuch as we consider it to be the duty of our kingly office to consult in every way the happiness of those who are subject to our sway, and as this object would be most effectually attained by putting a seasonable check to the practices of the wicked, we have judged it particularly necessary to repress the audacity of bad men who profess medicine, more from avarice than from conscientious and laudable motives, whereby divers injuries are done to the ignorant and credulous people, we therefore, &c. &c., do will and ordain, that there shall be established a perpetual College of grave and learned men, who may publicly practise medicine in our city of London and its suburbs, and within seven miles of that city in every direction; and we trust that these for their own credit, and for the public good, will take care, as well by their own weight and example, to discountenance the ignorance and the rashness of the before-mentioned evil-disposed persons, as to punish them by our laws lately promulgated, and by the regulations to be made by the same College; and in order that this may the more easily be accomplished, we have granted to Drs. John Chambre, Thomas Linacre, Ferdinand de Victoria, our physicians, and Nicholas Halsewell, John Francis, and Robert Yoxley, physicians, that they and all other members of the same faculty of and in the aforesaid city, shall become in fact and in name one body and perpetual commonalty or college.”

Having given the above extract, I declare it to be a faithful translation from the original Latin, and now call upon Dr. Elliotson, either to acknowledge his ignorance of the College charter, or to inform an abused and indignant public, why the Royal College of Physicians continue to neglect the important duties confided to their care for the general good of society.

I am, Sir,

Your very obedient humble servant,

A CENSOR OF THE FELLOWS.

Nov. 13th, 1830.

LONDON HOSPITAL.—MR. WALFORD AND  
THE PUPILS.

To the Editor of THE LANCET.

----- “Dost know this water-fly? In our last conflict, four out of five of his wits went halting off, and now he is governed with one: so that if he have wit enough to keep himself warm, let him bear it for a difference between himself and his horse.”—SHAKESPEARE.

SIR,—As Mr. Richards, “whose ductile dullness new meanders takes,” has not commuted paternity, but claims the last letter from the London Hospital as his own, he is entitled to an extra portion of attention, and shall receive renewed acknowledgments for the obligation he has conferred, unassisted by his seven-and-thirty colleagues. I no-where observe that he resumes the subject of Mr. Headington’s conduct in opposing a MEDICAL CORONER, because he disliked the candidate (for that was the alleged excuse); nor do I notice that he justifies his patron for his share in framing and administering the laws of that College, of which, in the innocence of his heart, Mr. Richards with transport proclaims he is about to become a member. There are two enemies from whom all thinking men desire to be protected. One is an indiscreet friend, and how much ought the Damon of Broad Street to lament the good offices of the Pythias of Bethnal Green! For without the devotion of the martyr of Bonner’s Row, Mr. Headington might ere this have returned to his obscurity, and been remembered only as one of the disinterested receivers of examination fees. The other foe to a foolish man is himself. Who can be severer on Mr. Richards than himself?

If in after days his descendants desire to preserve from oblivion the fame of their ancestor, they will reprint the last number of your Journal, which, if it endure as long as the Dunciad, and his letter be “redeemed from tapers and defrauded pies,” Mr. Richards will have done for himself what Pope did for Dennis; and Messrs. Blizard and Headington—whose names now only live on certificates and diplomas—will survive to posterity hand in hand with the hero of Bethnal Green!

Your Correspondent complains of not comprehending my letter; the fault is his own—I am not chargeable with his want of intelligence. I say not so of him—he is too intelligible to be mistaken; the calibre of his understanding is indicated by his intention to purchase the College diploma, and gravely describing it as an honour. But perhaps Mr. Richards is a fool of Fortune; such men are proverbially the favourites of the goddess; and, for the future, the certi-

ficat of dulness will be the College diploma, until it can be obtained for nothing. He dwells with peculiar complacency on his friend's wearing a blue riband, and, chuckling with delight, demands if that savoured of fear: certainly not, but it savoured strongly of folly, and was about as good a proof of independence as Malvolio's cross garters or yellow stockings. Mr. Richards modestly suppresses the description of his own decoration. Who can be at a loss in conjecturing what should adorn the summit of Mr. Headington's apologist? What best befits the brows of Mr. Richards I have already decided: if, however,—unlike that quadruped whose longitude of ear compensates for the brevity of his caudal appendage,—the gentleman should desire equality of honours for both his extremities, I respectfully suggest, that as his crest is a cap and bells, his motto, or tail-piece, may be,

"Sense, speech, and measure, living tongues, and dead,  
Let all give way, and *Richards* may be read."

I remain Sir, your faithful servant,  
WILLIAM AUGUSTUS WALFORD.  
Nov. 20th, 1830.

---

SIR WILLIAM BLIZARD.

---

*To the Editor of THE LANCET.*

SIR,—I would ask the benevolent gentleman who wrote the letter inserted at page 209 of your 375th number, why he excludes Sir W. Blizard from the benefit of his exculpatory endeavours, seeing that the worthy colleague of Sir W. has done nothing in the course of a reasonably long life which was not worthy of the knight himself?

I bear Sir W. no more love than does the Samaritan who has thus poured oil and wine into the wounds of Mr. Headington, yet I should be sorry to add to the burden of the knight's offences, by suffering him to remain undefended from the imputation of wronging the gentleman so feelingly alluded to as "the young man who was ill-used by the Blizards." The facts are these. On the retirement of Mr. Thomas Blizard, the most accomplished surgeon the London Hospital ever boasted, or probably will again, for one generation at least, Messrs. Headington and Frampton claimed the performance of a contract in favour of the latter, which these honourable gentlemen had entered into to "flap down new-fledged merit that would rise," and secure the return of Mr. Headington's partner as surgeon to the hospital. Sir W. took shame to himself for engaging to render all competition fruitless, and disinterestedly threw the weight of his interest

into the preponderating scale of his own wealthier apprentice. Such a compact it were a virtue even in Sir W. to violate: it was a cousin german to the *bond* business of Bartholomew's. I am, Sir, your obedient servant,

T.

November 7, 1830.

---

COLLEGIATE AVARICE.

---

*To the Editor of THE LANCET.*

SIR,—I am one of ten simpletons who, on Friday the 11th of this present month of November, presented themselves for plucking at the College of Surgeons. For the illumination of future pigeons, allow me to inform them how, and in what manner, the farce called Examination commences. The scene opens, not with an anatomical question, not with a surgical inquiry, not with an attempt to fathom the physiology of the examinee; but a request to be informed "*whether he has got his money with him, and whether it is in paper or gold?*"

I was so disgusted with this abominable solicitude for their extortionate fees, that had it not been the desire of my friends that I should become a member of their mis-called college, I would have demanded my certificates, rejected their examination, and mortified the vultures by taking away my "notes or gold." I am, &c.,

A MEMBER OF THE  
COLLEGE OF SURGEONS.

[This communication has been properly authenticated.—Ed. L.]

---

ST. BARTHOLOMEW'S HOSPITAL.—CIGAR SMOKING.

---

*To the Editor of THE LANCET.*

SIR,—That your very valuable publication, THE LANCET, has produced many essential reformations in our profession every one must allow, nor is it my wish to gainsay it; but as a student of Bartholomew's Hospital, I trust you will allow me to make a few remarks on the letter of a person subscribing himself "A Pupil," inserted in the Number of this week.

On his "*ars scribendi*" I shall make no comment, giving the numerous readers of your excellent hebdomadal publication, credit for some judgment in discriminating between the usually elegant compositions in THE LANCET, and the letter now before me, which in my opinion is a disgrace to a

*gentleman*, and a foul blot on the hitherto unsullied pages of your Journal.

The gentlemen who are there accused of smoking in the theatre, are many of them men of the first respectability—old pupils of the hospital, and esteemed by those who have the pleasure of their acquaintance. The theatre (especially lately) has been very offensive, on the return of the students from their dinner, attributable to the state of the bodies used at the anatomical lecture; cigars have, therefore, been introduced by some, and as I said before, by many of the most respectable in the hospital. A most offensive thing certainly! A person whose acquaintance they would have shrunk from, takes up his pen—perhaps in the very place which he accuses these men of patronising—"a London pot-house," and writes a letter, in which he abuses them as "certain puppies,"—men whose shoes he would willingly blacken to be admitted to their society.

As I am convinced that this letter was written in a vindictive spirit by the author, I am sure you will insert this reply; and in conclusion, I beg permission to ask you and your readers a few questions:—

1st. Is it consistent with the usual character of Mr. Lawrence, to give "a hint?" Would he not, as a man and gentleman, have desired its discontinuance?

2d. Do you think that had Mr. Lawrence expressed such a wish, the students, and those too his own pupils, would have continued the practice?

3d. Why did not this reformer come boldly forward, and, as a *gentleman*, mention Mr. Lawrence's dislike to it—if he could do so consistently with truth?

As this notice has not produced the effects desired by the author, or his insolence excited any feeling in men so superior to him, except contempt, I would advise him, as the only recompense he can make to your offended readers, to attempt another letter, apologetical for the abuse and ungentlemanly feeling expressed in his last.

I am, Sir,

Your most obedient servant,

AN OLD PUPIL

of St. Bartholomew's Hospital.

Saturday, Nov. 20, 1830.

---

CIGAR SMOKING.

---

To the Editor of THE LANCET.

SIR,—After Mr. Lawrence had concluded his lecture last night, he made a few well-timed and judicious remarks upon the practice of cigar-smoking in the theatre of the

hospital. Mr. Lawrence justly observed, that the rules of good breeding and civilized society alike demanded that those who were partial to smoking should forego that "pleasure" for the short period of one hour in the twenty-four, rather than offend those to whom the practice might be objectionable. For the manner in which this good-tempered observation was received by the class, I may fairly conclude that the obnoxious habit will be discontinued. As my last letter was written in a moment of irritation, I am willing to admit that I expressed myself in terms not altogether appropriate. Nothing can be further from my intention than to cast any imputation upon the characters of my brother students, or to call in question their claims to the rank of gentlemen. In a word, I am proud of being a member of the St. Bartholomew's class, which for pumber, talent, industry, and respectability, is not surpassed.

I am, Sir,

Your obedient servant,

A PUPIL.

Nov. 25, 1830.

---

MENDICANT MEDICAL IMPOSTOR.

---

To the Editor of THE LANCET.

SIR,—The caution which you gave in one of your late Numbers against the artifices of a medical man of the name, or assumed name, of *Villiers*, who is going about the country levying contributions, and living on the profession, I am sorry to say reached me too late to prevent my being gulled by his plausible stories.

The said Villiers said he lived at Bath, or was going thither; appears to be between thirty and forty years of age, middle-sized, with an unhealthy complexion; says he is subject to scirrhus or contracted rectum; tells a plausible tale with the most moving and lachrymose accent; carries with him extracts from THE LANCET, and documents recommending his case, carefully preserved in a leathern case, as well as a long and respectable list of subscribers and contributors to a very considerable amount, to alleviate his alleged distresses, some of whom have been dead for years.

I think it would be well to caution your readers once more against the scandalous exactions practised by this unworthy member.

I remain yours,

A CONSTANT READER.

[We regret that our correspondent has omitted his address.—ED. L.]

OBSERVATIONS ON THE INQUEST AT  
HAMPTON, BY DR. HARE.

*To the Editor of THE LANCET.*

SIR,—As I consider the midwifery case at Hampton to be of the utmost consequence to the profession, I take leave to offer a few brief observations upon it. The conduct of Mr. Bowen in resisting a consultation in a case of so much difficulty and danger, I consider as unwise and reprehensible as his practice. If in the whole medical profession a single educated and respectable man can be found hardy enough to justify him, I can only say I am sorry for it.

He has great reason to congratulate himself upon the escape he has had, by the finding of a packed jury, and by the luminous and scientific observations of a non-medical coroner.

It ought to be held out as a beacon, illuminated with gas, and floated to the whole profession, to warn them of the danger of following such an example.

I remember to have seen a man with a lighted lantern placed at the entrance to certain ladies' apartments, in order to apprise unwary customers of their danger, this was called burning them out, hence, I suppose, the phrase, "a burning shame." Now is it not "a burning shame" that such a case should occur, in the nineteenth century, so near a metropolis famed for science and scientific men?

L. HARE, M.R.C.S.L.

13, Upper Gower Street, Bedford Square.

November 1st, 1830.

## ST. BARTHOLOMEW'S HOSPITAL.

### OPERATION FOR CATARACT.

On Friday last, Mr. Lawrence performed the operation for the extraction of cataract on the right eye of a man about sixty years of age.

The patient, being laid on the operating table, his head supported by a pillow, the upper half of the cornea was divided, and the lens lacerated in the usual manner. After a short time, the lens not being protruded by the efforts of the eye, slight pressure was made on it by means of Daville's curette. This had the effect of throwing the lens upwards and forwards against the posterior surface of the iris. The operator then introduced a needle through the pupil, and succeeded in removing the lens from the situation it then held; and pressure being again employed, a portion of the vitreous humour was discharged. Foiled in this

attempt, Mr. Lawrence introduced the curved needle a second time, and carried it behind the lens, which he endeavoured to transfix, but in vain. Recourse was again had to pressure, which was followed by a further escape of the vitreous humour, and the needle was then introduced a third time, but could not be made to pierce the lens, on account of the facility with which it slipped away under the slightest pressure against it. At length the curette was passed through the pupil, and the lens was immediately extracted. It was of an amber colour, and about half the usual size; to which Mr. Lawrence said the difficulty he had met with might be attributed. The patient was then removed to a room that had been darkened, a lotion was applied to the eye by means of linen rag, and a strict antiphlogistic regimen enjoined. About one third of the vitreous humour was discharged during the operation. The patient is going on well.

J. Reeve, whose case is recorded in THE LANCET for October the 16th, went on very well until last Friday, when the stump became very painful and swollen. At 4 o'clock P.M. on that day, a slight hæmorrhage took place, which was suppressed by means of cold cloths; a tourniquet was applied loosely round the limbs. Ten P.M. There has been no recurrence of the bleeding; the stump feels hot, and fluctuation can be distinctly felt in it. On Saturday morning at three o'clock, hæmorrhage again occurred, and the house-surgeon was sent for, and being unable to find the vessel that was bleeding, he tightened the tourniquet and sent for Mr. Vincent, who arrived in a very short time. The man had lost about a pound and a half of blood. Mr. Vincent separated the adhesions which the severed edges of the stump had formed, and found a cavity containing a large quantity of coagulated blood. None of the ligatures had separated. Mr. Vincent found that the posterior tibial artery had ulcerated above the ligature, and immediately cut down and tied the artery just at its origin. The bleeding then ceased, he became very pale, and his pulse could with difficulty be felt. Some wine was given him; his pulse rose, he slept well the remainder of the night, and has since gone on very well.

## LONDON HOSPITAL.

### EXTIRPATION OF THE RIGHT SUPERIOR MAXILLARY BONE AFFECTED WITH OSTEO-SARCOMA.

A MAN, the subject of this operation, apparently about 40 years of age, was brought into the operating theatre on Wed-

nesday, Nov. 17th, having a tumour which occupied nearly the whole of the right side of the face. The skin covering the antrum was of a dark-red colour, and matter was seen oozing from an opening just over the anterior margin of the masseter. The patient being laid on his left side, the first step of the operation was to secure the external carotid artery immediately after its transit beneath the digastric muscle, opposite the angle of the jaw. This was done by making an incision in the direction of the posterior belly of this muscle, by which the lower margin of the parotid gland was exposed. The dissection was then continued until the artery could be felt, pulsating in the depth of the wound; and a ligature was, with some difficulty, passed beneath it. In tying the artery, however, the ligature unfortunately broke, and another was passed under it, which occasioned a little delay in the operation. Very little blood was lost; and, considering the depth of the artery, which was increased by the swelling of the whole cheek, we consider that the operation was very dexterously performed. A consultation then took place between the surgeons in an adjoining room, the particulars of which, however, did not transpire. The operator then proceeded to lay bare the tumour, which was effected in the following manner: An incision was commenced at the angle of the mouth, and carried obliquely upwards and outwards, as far as the superior margin of the zygomatic process of the malar bone, in which the coronary and facial arteries were divided, and immediately secured. Another incision was then commenced from the same point, and carried vertically upwards to the ascending process of the superior maxillary bone. A triangular flap was thus formed, which was dissected upwards as far as the edge of the orbit, by which the greater part of the tumour was exposed. The posterior part of the cheek was then dissected downwards, by which the whole of the tumour and the teeth were completely laid bare. The tuberosity of the superior maxillary bone and the palate bone were now separated from the pterygoid process of the sphenoid with Liston's bone nippers. The malar bone was next cut through, the division extending into the spheno-maxillary fissure. The ascending process of the superior maxillary bone was then separated at its basis—the first incisor tooth was now extracted, and the maxillary bones separated at the inter-maxillary suture. All this was easily performed by the aid of the same instrument. Some little force was next exerted, by which the tumour, the maxillary bone, and perhaps the palate bone, were loosened, and the soft parts divided with a curved double-edged scalpel, and the whole easily withdrawn.

This second step of the operation was most coolly and dexterously performed, occupied only thirteen minutes, and was attended by a much less loss of blood than might have been anticipated. There were no vessels that required ligatures, and blood was prevented falling into the pharynx by the depending position in which Mr. Scott kept the mouth. Small pledgets of lint were now introduced, and the edges of the incisions connected by sutures. The whole surface of the cheek was covered with adhesive plaster; and Mr. Scott requested the porters to carry the patient to his bed, which we were astonished to hear him object to, saying, that he was quite capable of walking, which was allowed him. He displayed amazing fortitude; and his pulse, which flagged a little during the operation, regained its power before he left the theatre.

The whole surgical staff of the Hospital was present, and Mr. Scott was ably assisted by Mr. Luke. We can say nothing of the structure of the tumour, as it had not been examined when we left the Hospital.

#### FRENCH ENGLISH.

A FRENCH writer, who has edified his readers in a late number of the *Journal Hebdomadaire*, with a "biographie" of John Abernethy, thus quotes a well-known passage:—

"Tongues in the trees, books in the running brooks,  
Sermons in stone, and good in every thing."

The second figure is thus translated; "des livres dans les sources qui murmurent."

The works of M. Abernethy are described as, 1°. On the constitutionnal origin, treatment of local diseases on aneurismes; 2°. On diseases resembling syphilis, and on diseases of the urethra; 3°. On the injuries of the head, and miscellaneous subjects; 4°. On lumbar abscesses and tumors; 5°. Lectures addressed to the college of surgeons, and on the theory and practice of surgery.

Dr. WRIGHT.—We strongly recommend to the notice of the profession the "Minutes of Evidence," now published by Mr. Highley, Fleet Street, containing charges against Dr. Wright of Bethlem Hospital. We understand that the doctor will publish his "Reply" in a very few days.

#### TO CORRESPONDENTS.

## MEDICAL JURISPRUDENCE.

PRACTICAL COMMENTARIES ON

DR. CHRISTISON'S PROCESSES

OF DETECTING POISONS.

### ANTIMONY AND ITS PREPARATIONS.

THE preparations of antimony which are most likely to engage the attention of the toxicological chemist, are the tartar emetic, the precipitated sulphurets, and the chloride, or butter of antimony, which last, though scarcely noticed by Dr. Christison, is yet of no trivial importance. The physical properties of the two former require no notice; the last, it will be remembered, is prepared by boiling the sulphuret of antimony with muriatic acid, when sulphuretted hydrogen is expelled, and a chloride of antimony formed, which usually exists in the state of a gelatinous fluid, and which, when thrown into an alkaline solution, is decomposed, a white protoxide of antimony being thrown down. All the soluble preparations of antimony are decomposed by many organic substances, such as astringent vegetable infusions, &c.; they are also decomposed by sulphuretted hydrogen gas, an orange-red sulphuret of antimony being formed, which sulphuret, when treated with caustic potash, or subjected to the action of hydrogen gas, forms either a sulphuret of potassium or of hydrogen, and metallic antimony is set free. Metallic antimony, again, is a blueish-grey metal, fixed in the fire, except when exposed at the same time to currents of gaseous matter; when heated in an open tube, it is oxidized with the production of a white shining vapour.

Such are the leading chemical features of No. 379.

antimony, a correct understanding of which is essential before the processes approved by our author can be duly investigated.

Various authors have at different times recommended particular processes for the detection of this tribe of poisons; of these we may particularize that of Orfila, and the more recent one by Dr. Turner, which latter Dr. Christison recommends to be adopted. We quote the author's description, illustrated by a diminished drawing of the apparatus employed. It is necessary also to extract his brief account of Orfila's method:—

"Professor Orfila recommends the following compound process. Either the antimony exists in solution, or it has been rendered insoluble by vegetable principles. The suspected matter being filtered, therefore, both the fluid and the matter remaining on the filter must be submitted to analysis. The fluid is to be treated with sulphuretted hydrogen, and the precipitate collected and reduced with potash in a crucible. The solid part is to be incinerated, and reduced also. In both cases globules of metallic antimony are procured if that metal was present in the mixture.\*

"This method is liable to some material objections. In the first place, if the fluid is alkaline, the sulphuretted hydrogen will not act; secondly, I have frequently found that the process of reduction does not answer on the small scale; and lastly, the double process may be dispensed with.

"A much better method of analysis is the following very simple and satisfactory process proposed by Dr. Turner. The subject of analysis is to be acidulated with a little muriatic and tartaric acids. The former will coagulate various animal principles which may be present. The latter Dr. Turner has found to possess the property of readily dissolving all precipitates whatsoever formed by reagents with tartar emetic, except that caused by sulphuretted hydrogen. Hence the addition of tartaric acid

\* Toxicol. Gen. i, 481.

brings the whole of the antimony into the fluid, and consequently one-half of Orfila's process is dispensed with. The fluid so prepared is to be filtered, and a sulphuret formed and collected in the usual way. Dr. Turner found that the next step, the reduction of the sulphuret, cannot be effected on the small scale even in a crucible, much less of course in a tube; and on examining the flux, he discovered that a part of the sulphuret escapes decomposition, and that the metal which is reduced is too finely divided to be distinguishable. He was therefore led to propose the process of reduction by hydrogen (p. 354), which will develop antimony characteristically from only a tenth part of a grain of the sulphuret."

The experiment is performed by passing a current of hydrogen gas, generated in the larger bottle from diluted sulphuric acid, and iron filings or zinc. At page 354, Dr. Christison describes it thus:—

"The best mode of showing the presence of antimony in it, is the method of Dr. Turner, who proposes to place a little in a horizontal tube, to transmit hydrogen gas through the tube by means of the apparatus represented in the figure, and, when all the air of the apparatus is expelled, to apply heat to the sulphuret with a spirit-lamp. Sulphuretted hydrogen is evolved, and metallic antimony is left if the current of hydrogen is gentle, or it is sublimed if the current is rapid."†

"If the stream of gas is slow, the metal remains where the sulphuret was; if the stream is rapid, it undergoes a spurious sublimation, and condenses on the tube either in detached crystals or in the form of a shining crust. When there is much animal or vegetable matter present in the sulphuret, the metal is not always distinctly visible. In that case Dr. Turner recommends that it be heated in an open tube, when it oxidates and sublimes in the form of a white powder, which glimmers, but is not crystalline and adamantine like the oxide of arsenic.‡ A better method, however, is to dissolve the antimony by the action of nitric acid on the mixed material and broken fragments of the tube, and to throw down the orange sulphu-

ret again from the neutralized solution by means of sulphuretted hydrogen.

"Dr. Turner's method I have repeatedly found to be successful and manageable. But some practice is required to transmit the hydrogen gas with the proper rapidity. The gas ought to be allowed to pass for some time before the spirit-lamp flame is applied, otherwise the oxygen remaining in the apparatus may cause an explosion, or will oxidate the metallic antimony formed by the reduction of the sulphuret. Whenever the reduction of the sulphuret begins, the tube is blackened on account of the action of the sulphuretted hydrogen on the lead contained in the glass. This obscures the operations within the tube; but on subsequently breaking it, the metallic button or sublimate will be easily seen. I have generally found, that when the sulphuret was considerable in quantity, and the gaseous current slow, the metal remained where the sulphuret was; but if the mass of sulphuret was small and the current rapid, then the metal was sublimed and condensed in minute scaly crystals of great brilliancy.

"In a late paper, Orfila has defended his process against Dr. Turner's criticisms, and states, that either in a crucible or (if the quantity of sulphuret is small) in a tube heated by the blow-pipe with a "lampe à quatre mèches," globules may be procured; and that he has procured them in this manner from a sixth part of a grain with the black flux, or with a mixture of charcoal and a little potass.\* I can only say that I have often tried Orfila's process, and always failed to procure distinct globules, unless the heat was intense, and then I have only sometimes succeeded. This process of reduction is certainly precarious; and, notwithstanding what Orfila has said in favour of his own method and against that of Dr. Turner, the latter has appeared to me much superior."

From repeated examinations of Dr. Turner's process, we feel entitled to assert, that though theoretically perfect, it is practically unsuited to the purposes of medico-legal analysis. The objections we consider it exposed to, are, in the first place, the great difficulty to its performance by unpractised persons, who always constitute the majority of persons interested in these cases, a difficulty which arises as well from the impossibility, in many instances, of obtaining tube apparatus of so complicated a kind, as, from the nicety of adjustment and manipulation, the experiment requires; secondly, that unless the hydrogen gas be very

† On the Detection of Antimony in mixed Fluids. Ed. Med. and Surg. Journ. xxviii. 71.

‡ Edin. Med. and Surg. Journ. xviii. 75.

\* Arch. Gén. de Médecine, xvi. 85.

pure, the process increases in all its difficulties; if iron filings be employed, from the carbonaceous impurities and the sulphur which they contain, carburetted hydrogen and sulphuretted hydrogen are liable to be generated, and the decomposition of the sulphuret becomes, to say the least, extremely uncertain. If zinc, on the other hand, be used, and the heat be applied for a length of time, *metallic zinc* is liable to be deposited in the tube, if there be any matter present, such as sulphur, capable of combining with the hydrogen and setting free the metal which it holds dissolved or combined with it in considerable quantity. We have, indeed, more than once observed a metallic appearance to be produced in this way. It is true that the first objection is but of a conditional kind, and, in another respect, would apply against lithotomy or any other surgical operation; it may be also said, that it becomes as much the duty of a medical man to provide himself with analytic instruments, as with lancets or amputating knives. We freely admit this, and we will also allow that the third objection may be obviated by using pure iron, and ascertaining the purity of the gas by a previous trial, viz., by conducting it through a solution of acetate of lead, which will be blackened if it contain even a trace of sulphuretted hydrogen; but still we must repeat, on the authority of our own experiments, that even in comparatively practised hands, with every attention to purity of materials and adjustment of apparatus, the reduction of the metal is always uncertain, and unsatisfactory when obtained. We have repeated the experiment three-and-twenty times, and only succeeded four times in obtaining a portion of metal, *the properties of which could be recognised*. This, it may be argued, proves nothing but our own incompetency; but while we admit our inferiority in experimental adroitness to Dr. Christison or Dr. Turner, yet as we have practised the experiment over and over again, and as we are in general successful in equally minute investigations, we are inclined to believe ourselves entitled to offer rather a positive opinion on the subject.

But while we start objections to Dr. Turner's process, we do not intend to adopt that of Orfila, which, in every respect, is less entitled to confidence. Indeed, it is

little short of ludicrous to hear of the employment of a *crucible* in delicate operations of this kind; it brings us back to the homely days, when the reduction of arsenic was performed in a luted teapot, by the heat of a huge charcoal fire. We may notice also that Dr. A. T. Thomson, in the appendix on poisons attached to his valuable *Conspectus of the Pharmacopœias*, falls, in one instance, into the same whimsical error.

The truth, we believe, is, that all the learned authors have committed the error of doing a work of supererogation in seeking for the reduction of the metal at all, and that they might as well refuse to admit the recognition of the sulphate of baryta, unless they had previously obtained "barium," its metallic base. In the first place there is no metallic sulphuret whatever, prepared by transmitting sulphuretted hydrogen through a solution, which even remotely resembles the rich red colour of the sulphuret of antimony; secondly, if further proof be required, just as conclusive evidence can be obtained from one-twentieth—nay, one-fiftieth part of a grain of this sulphuret, and with infinitely less trouble than is necessary for the reduction process. The annexed simple experiment will demonstrate the correctness of this assertion.

Having transmitted the sulphuretted hydrogen through the suspected liquid, prepared as Dr. Turner judiciously recommends, the liquid should be boiled, and allowed to cool and deposit the precipitate; the greater part of the supernatant fluid should then be removed with a suction tube, leaving as much as is sufficient to suspend the precipitate till it is decanted upon a watch crystal; it should then be washed with distilled water on the crystal, the fluid removed by the cautious use of a fine-drawn capillary tube, and it should next be placed near the fire-place till perfectly dry.

This plan of decanting and washing will be found to possess many advantages over the filtering which Dr. Christison recommends; filtering should very seldom be employed in analyses of this kind, so great is the loss of materials which it usually occasions.

About ten drops of muriatic acid and five of nitric acid are next to be dropped over this precipitate, and the crystal being supported on a ring of copper-wire, the fluid is to be

boiled over a small spirit-lamp flame. In three or four minutes the red colour of the sulphuret disappears with effervescence, and an extremely small yellow globule of sulphur is seen swimming on the surface of the fluid, which should then be allowed to cool, and the little particle of sulphur removed with the point of the capillary tube. The fluid should now be evaporated to dryness, when a transparent gummy residuum, the chloride or butter of antimony, remains. If a few drops of distilled water be now dropped over this, an insoluble white powder, the protoxide of antimony, is immediately formed. The process of washing is to be repeated again, the white powder dried by a gentle warmth, and, finally, heated over the spirit-lamp flame, when it changes to a beautiful golden yellow.

We have thus a chain of evidence simply and easily obtained, and withal indisputable in its kind. There is no sulphuret of the same red tint as that of antimony—there is no red sulphuret but that of antimony, which, decomposed by nitro-muriatic acid, will yield a residuum precipitable by water; and, thirdly, there is no powder but the protoxide of antimony which similarly obtained, becomes of a yellow colour when exposed to heat. The theory of the process is also readily understood. The process now proposed, possesses moreover the advantage of extreme facility of execution; a watch-glass can be procured any-where, and the whole investigation completed in half an hour, without the necessity of constructing the pretty, but complicated apparatus, represented in our engraving. We are by no means inclined to question the necessity of obtaining the metallic base of poisonous preparations as a general rule. Antimony, however, constitutes the exception, as will be seen in our notices of lead, copper, silver, mercury, and arsenic. In this instance it is entirely unnecessary; and the attempt at the reduction of the metal will usually fail, and, moreover, prevent the application of much more certain experiments.

As this is the first occasion on which we have alluded to the transmission of sulphuretted hydrogen gas through suspected fluids, it may be useful for some of our remotely situated readers to inform them, that it is best prepared by pouring very dilute sul-

phuric acid over powdered sulphuret of iron, prepared by holding a roll of sulphur against a bar of iron at a white heat, and collecting the drops produced in a vessel of water. A double-necked bottle with a bent tube, such as represented in the woodcut, is the best for the purpose, if it can be obtained; if not, a common six-ounce phial may be furnished with a tube of the same form; for this purpose a piece of barometer tube may be bent to the necessary form in a spirit-lamp flame, or an efficient substitute for this may be constructed with large quills adapted together by air-tight paper joints.

Finally, it is of essential importance to ascertain whether tartar-emetic or antimonial powder has been administered before the death of the individual, whose case is investigated. If it have, it is perfectly plain that no chemical evidence can be of any importance. We may remark here, that to the interfering presence of poisons used as medicines, Dr. Christison does not generally pay the special attention which the importance of such a fallacy demands.

---

*A Practical Treatise on the Diseases of the Eye.* By W. MACKENZIE, Lecturer on the Eye in the University of Glasgow, &c., &c. London: Longman and Co., 1830. 8vo. pp. 860.

NOTWITHSTANDING the great number of books on diseases of the eye which have been published in this country, a complete account of the affections of this important organ has been hitherto a desideratum in our medical literature. There exist, it is true, a few general works on the subject, but these, though certainly not without value, are too brief, or too little comprehensive; it is with very great satisfaction, therefore, that we have perused the excellent and comprehensive treatise of Mr. Mackenzie; it contains, in a comparatively small space, all the information that either the student or the practitioner can, under ordi-

nary circumstances, require,—information which he might previously have sought for in vain, or could have obtained only by consulting many separate works. We would not, however, have it supposed, that the book before us is a mere compilation, for such is by no means the case. In a work of this kind, which must necessarily be founded on the experience not of one, but of many, it was indeed impossible to introduce much really new or original matter; but while the author has, with great industry and research, collected the statements and opinions of numerous writers, English and Continental, especially those of the German surgeons; with whose valuable labours on this subject he appears to be very familiar, he has interwoven them with the result of his own observations and experience, in a manner which increases their value, and shows him to be thoroughly and practically acquainted with the diseases of which he treats.

The arrangement, which is chiefly according to the textures of the part, beginning with the external or accessory organs, and ending with the retina, is at once scientific and convenient, and the division is sufficiently minute, without being carried to the absurd extent, and involving the almost endless nomenclature in which some writers have delighted, more to the confusion than the edification of their readers. Although it is not our intention to give a detailed account, or an analysis of the work, we shall notice a few parts of it here and there, in which the facts or opinions advanced by the author are altogether new, or differ from those which have been generally received, or may seem, for any other reason, to be particularly worthy of attention. We shall begin with an extract from the general observations on ophthalmia, in which the author forcibly combats the absurdity of considering all the inflammations of the eye as one and the same disease, and of attempting to apply the same treatment to them all.

“Every different texture of the eye, as it possesses both physical and vital properties peculiar to itself, must suffer differently from the several processes of inflammation. In many cases the modifications of inflammation from differences of texture in the parts affected, are displayed with much distinctness in the eye; in other cases these modifications can be judged of only from

their consequences, and by a very minute observation of the derangement which remains in the organisation of the part which had suffered; while in other cases, from the delicate texture of the part, or its hidden situation in the eye, they may altogether escape observation.

“The conjunctiva, sclerotica, cornea, iris, crystalline capsule, and retina, present a series of the modifications of inflammation, to which I have just now referred, sufficiently distinct to convince the most sceptical of the truth of what I have asserted, and sufficiently striking to rouse the most inattentive to research. The muco-cutaneous conjunctiva secreting a flood of purulent matter, as in the ophthalmia of new-born children—the fibrous sclerotica, affected for months with rheumatic inflammation—the transparent fibro-cartilaginous cornea, becoming opaque, or being destroyed layer after layer by a penetrating ulcer—the erectile iris, losing all power of executing its motions of contraction and expansion—the crystalline capsule, pouring out coagulable lymph from its serous surface, and this lymph forming the medium of morbid adhesions—the nervous action, too deeply-seated to be observed immediately, but in a few hours losing its inconceivably delicate sensibility—these are facts in which are displayed the modifications of inflammatory action, and the various consequences of inflammation, fully as distinctly and as strikingly as they are manifested in any other, nay, in all the other, parts of the body together. There are other circumstances besides differences of texture which modify the inflammatory affections of the eye, which render this subject very extensive in the discussion, and cause the diseases to be occasionally very perplexing in the treatment. They are under the influence of peculiarities and certain artificial states of the constitution, and of constitutional diseases; and they are subject to innumerable variations from the influence of those inscrutable connexions called sympathies, scrophula, syphilis, gout, and that state of the system which we may call mercurialism, are each of them either capable of exciting inflammation in different parts of the eye, or at least of communicating to an inflammation, excited by other causes, such differences in character as shall often render it difficult to recognise a disease with which we were well acquainted in its simple or idiopathic form.”

Mr. Mackenzie's opinions on the nature and pathology of some few of the diseases of the eye, differ in some respects from those which are entertained by surgeons of great authority on these points. Thus, in opposition to Mr. Lawrence, he maintains

that gonorrhoeal ophthalmia is sometimes produced by metastasis; and adduces in support of this opinion, the cases described by Mr. Arnott and Dr. Hall, in the *Med. Chir. Trans.*, where the inflammation of the eye certainly appeared to depend on metastasis, or on the transmission of pus by the veins; these cases, however, appear to us to bear very little upon the point in question; and although the author, in conformity with the German oculists, recommends that, in addition to the other remedies, means should be adopted to bring back the discharge in the urethra, he does not mention any case where he knew it to have been suppressed.

The distinction between idiopathic and syphilitic iritis, he does not consider to be so well defined as Mr. Lawrence represents it to be. He is, however, far from denying that the latter is a separate form of disease, indeed, he mentions another species of iritis, in addition to those with which we were acquainted, viz., "scrofulous iritis," of which he gives a very marked case, where it occurred without inflammation of the conjunctiva in one eye, and with pustules and an ulcer at the base of the cornea in the other. It was treated chiefly with salomel and opium, and the patient, a boy sixteen years old, rapidly recovered as soon as the mouth was affected. With regard to glaucoma, on the nature of which various opinions have been entertained, he believes that it consists principally in the absence or deficiency of the pigmentum nigrum, and that the green colour is owing to the bluish light reflected from the bottom of the eye passing through the yellowish or amber-coloured lens; and observes, "in confirmation of this, if the lens is removed in this disease, or sinks to the bottom of the dissolved vitreous humour, the green appearance is almost entirely lost." He states also that in a great number of glaucomatous eyes which he carefully dissected, the vitreous humour, though dissolved, was perfectly transparent, and that he never found the retina materially altered, much less in that thickened state which Scarpa describes, attributing to it the principal phenomena of the disease. He is, however, inclined to ascribe the disease primarily to the morbid state of the vitreous humour, which by its pressure may induce the absorption of the

pigmentum; and observes that the excess of this fluid is probably in the same manner the cause of the total blindness which results at last.

The methods of treatment recommended are in every case judicious, and appear to be founded rather on practice than on theory; rather on his own experience than on the reports of others. There is, however, little in them which need be noticed here.

In all the purulent ophthalmiae, and in most inflammations of the sclerotics, he strongly recommends the solution of nitrate of silver, from which he has obtained the most striking benefit. The acetate of lead he thinks ought not to be used as an application to the eye, as it tends to produce opacity of the cornea whenever there is any ulcer or abrasion of that part.

He employs bleeding to a considerable extent in most cases of rheumatic inflammation of the eye, and observes,

"I feel myself obliged to differ entirely from Mr. Wardrop in his opinion that patients affected with rheumatic ophthalmia neither bear bleeding to a great extent, nor are much relieved by this remedy; he has even stated the little relief afforded by bleeding in this disease, as one of its distinctive characters. This entirely disagrees with my experience, and is, I apprehend, altogether contrary to what we observe in other rheumatic affections, &c."

Probably both writers are to a certain degree correct, each being justified by his experience in making the statement which he has done, and the safest way, perhaps, is to be guided rather by the particular circumstances than by general rules, in the treatment of this as well as the other forms of so variable a disease. In the latter part of the sentence we have quoted, however, Mr. Mackenzie certainly goes too far; very various results in reference to bleeding have been observed in the treatment of rheumatism affecting the other parts of the body, and we know that one of the best hospital physicians in London has almost entirely discarded the remedy in question, in this complaint, which he has found by experience may be more safely and more effectually combated by other means.

It can hardly be expected that a work of this magnitude should be altogether without faults, but under this head we have only to

notice the unnecessary length of the chapters on diseases and injuries of the orbit and soft parts around it (these belong rather to general surgery, and are almost out of place in a work exclusively dedicated to the diseases of the eye); the repetition of the same subject in the two sections on "nævus maternus," and on "orbital aneurism by anastomosis;" and lastly, the denial of the occurrence of intermittent ophthalmia, two very marked cases of which have been described in German journals, and are given in Nos. 290 and 330 of *THE LANCET*.

These are, however, of comparatively little consequence, and we can most strongly recommend the work to the attention of our readers.

#### SINGULAR MALFORMATION OF THE EYES.

In a late number of Schweigger's *Journal* we find a report by Professor Marx at Brunswick, on a girl about 21 years of age, in whose eyes the lens is situated immediately behind the cornea; the iris is closed, but is very thin, and is pushed backwards so as to be almost funnel-shaped. Both lens and iris are completely transparent, so that the choroid may be seen through them. The individual could see very well until lately except in a very strong light; and it was only when the lens in the right eye began to become opaque, and she applied for surgical aid, that the singular position of the lens was discovered. In the left eye there seems also a cataract to be forming. The eyelids are remarkably thin and wrinkled, and appear almost to indicate a tendency of nature to compensate in some degree the absence of the natural function of the iris.

#### METALLIC MIXTURE FOR INJECTING ANATOMICAL PREPARATIONS.

A GERMAN *Journal* recommends for this purpose an alloy consisting of

177 parts of weight of tin	
310.....	lead
101,26 .....	quicksilver
497.....	bismuth,

which might accordingly be considered as a compound of three atoms of tin, three atoms of lead, seven atoms of bismuth, and one atom of quicksilver. The best method of preparation consists in slowly heating the

bismuth, tin, and lead, with a little powdered charcoal until the mass comes into fusion; it is then removed from the fire, and the quicksilver gradually added after having been previously heated. The mixture has the brightness of silver, is perfectly fluid at 173 deg., and becomes solid at 140 deg.

## SKETCHES OF THE MEDICAL SCHOOLS OF SCOTLAND.

No. XXVIII.

DR. GRAHAM.

WE are apprehensive of committing a breach of pictorial propriety in attempting the likeness of a botanist at this uncongenial season of the year, when Flora scarcely affords a flower to fill up the back ground of the canvass. But as Dr. Graham, indifferent to the indications of the thermometer, has set us the example of treating botanical subjects in winter, by the delivery of a course of lectures, we shall imitate his laudable innovation, though the ink were to congeal as it flowed from our pen, and we produced something as misshapen as an iceberg, instead of an exact similitude of the dashing, handsome, and highly intelligent Professor who presides over botany in the University of Edinburgh. We give this early intimation of the general character of the object of the present sketch, lest it might be supposed we were about to exhibit the portrait of a venerable old swain, with silver locks, buckles in his shoes, a pea-green vest, and a glass dangling from his neck; of one, in short, of those teachers of the by-gone school of botany whose attributes pointed them out as a sort of personification of the Epicene gender, or, like the themes of their own meditations, an amalgamation of both sexes in the same individual. With such respectable old ladies, as if unsexed by the serenity of their pursuits and the indolence of their habits, Dr. Graham holds no qualifications in common. Between Dr. Graham and the associations which the tuition of botany is too apt to excite in the recollections of most medical men, there is a most felicitous discrepancy indeed, the science being considered by them as trivial in its objects, and an unnecessary addition to the knowledge of a practical physician, an opinion which the habits of those by whom it was taught but tended little to overturn. Active however in manner, acute in his perceptions, comprehensive in his

research, and painstaking in the communication of instruction, you are constantly startled into wonder, during one of Dr. Graham's lively prelections, how an individual of such buoyancy of manner—how one, the decision of whose character, and rapidity of whose movements, point him out as fitter for the extirpation of disease than for bending in patient scrutiny over the evolving miracles of the microscope, should have become the investigator of the delicate and complicated organization of the vegetable world. It is difficult, indeed, to reconcile the apparently contradictory attributes of his character, or to concentrate into one view the multifarious qualifications evinced by him in the discharge of his various official duties, whether as a teacher of botany, a clinical lecturer, or a practical physician. Like many others called to fill important situations without time to prepare a regular digest of the science which they taught, out of a systematic course of study, Dr. Graham has laboured, and not unsuccessfully, to compensate for a deficiency in early education. Aware of the connexion existing between the different branches of medical science, he has endeavoured to grapple with them all, and if he has not attained his objects fully to the extent of those who make each department of the healing art a separate subject of cultivation, he has at least carried along with him, in his hurried career over this extensive field of study, a sufficiency of its fruits and flowers to furnish at once a substantial and agreeable bouquet for his pupils in botany. Principally occupied in didactic pursuits, he is necessarily better known as a teacher than a writer on botany; but what he looses in fame is amply made up in utility to his class by the excellence of his lectures. His facts in illustration of his positions are in general happily selected, and his reasoning founded on them, the productions of a vigorous and independent mind, which brooks no authority but that which it can thoroughly understand. Excellent, however, as are those speculations on the higher departments of the science with which he enlivens his course, it is in the less ambitious, but not less useful departments of practical botany that his merits are most conspicuous. In estimating the comparative value of the various systems or methods of botanical arrangement, he has, we think, judiciously adhered to that of Linnæus, and made it the basis of his lectures, notwithstanding the unfounded imputations cast on it by recent writers, particularly by Mr. Lindly, of London, who facetiously informs us, in the preface to his *Natural Classification of British Plants*, that "it has almost disappeared from every country but our own, and ought now to find no other place in science than among the records of things

whose fame has passed away"! The gross ignorance, and we must say insolence, evinced in this passage, need no comment, nor the "sexual system" of Linnæus a defence at our hands—a system which will live as long as science itself shall be cultivated; in fact, it is the only one adapted to the botanical pupil in his first steps in the science, as it is, after all, the only one by which the name, at least, of plants can be readily recognised in the field. We have repeatedly seen the experiment of two students, the one taking Mr. Hooker's *Flora*, the other the *Synopsis* by Mr. Lindley; and in nine cases out of ten, the student making use of the latter could not recognise a single plant, or arrive at its name, by its assistance, while the pupil following the Linnæan system, adopted in Mr. Hooker's work, made out every plant that presented itself to his view. In his use of this admirable system, Dr. Graham takes the greatest pains; the orders in Smith's *Compendium* are gone over by him during the course, and specimens in illustration of the genera and species belonging to each abundantly supplied and luminously explained. In addition to these minute notices of each plant, Dr. Graham holds daily examinations in a given portion of each of the orders, and what rarely indeed occurs on such occasions, not only renders them highly instructive, but even agreeable to the class, by the affability and elegance of manner with which he propounds his questions to his pupils, who are seldom disposed to bear this species of catechetical scrutiny in public with a good grace. The style in which his lectures are composed is at least as peculiar as the matter of them is instructive, being as punctiliously elaborated as an Oxford prize-essay, or a Christmas declamation at one of our great schools. There is, perhaps, too much straining in them after effect, a fault, however, which may be the more readily overlooked when the illiteracy and negligence displayed in the compositions of many of the professors of the present day are recollected. Though philosophy and science disdain the meretricious aid of rhetorical embellishment, even truth itself may be degraded by the dress in which it is presented to our understandings; and though Dr. Graham's phraseology may be, on certain occasions, too florid, his sentiments too witty, and his periods too pointedly antithetical, we would prefer the excess of his merits to the poverty of phrase of other lecturers. He has obviously a passion (for such we may call it) for literary displays of this description, and never, when the subject admits of the effort, neglects treating his pupils to one of those sublime speculations on the more abstruse questions involved in the cultivation of botany; such, for example, are his

essays on generation, the ultimate structure of matter, his defence of the Linnæan system, and though last not least, his criticisms on the writings of Mr. Andrew Knight. In these studied lucubrations he puts forth his whole strength, and if to the practised writer they appear somewhat over-done, it must be allowed that they are admirably calculated to enliven the tedium of a long course of lectures, and to keep alive the attention of a class, which soon fails if not stimulated occasionally by such exhibitions. If Dr. Graham did not succeed in rendering the delivery of his prelections agreeable, he would be certainly without an apology, having every physical essential of oratory, a clear intelligent eye, a forehead of unruffled placidity, a loud yet harmonious voice, and features of such expressiveness and manly beauty as to interest the most phlegmatic auditor or contemner of external appearances. With such natural advantages, the delivery of eloquence becomes a matter of facility, a fact of which Dr. Graham alone appears to be unconscious, and which casts an additional charm over his manner in the public perusal of his lectures. Seldom, indeed, has a professor's chair been filled by one of higher personal endowments, and habited in his official robe, he looks, during the enunciation of one of his favourite passages, as if inviting the artist to transfer him to the canvass as the *beau idéal* of a professor of botany. A "stage player," or a "reader of Shakspeare," might indeed take umbrage at the oftentimes unvaried emphasis with which he declaims common-places; but as these are of importance to the student, as they are to be impressed on the memory, and not merely to please the ear, the energy of action and elevation of voice with which he enunciates his discourses, are at least judiciously employed to keep up the attention of the audience, though they may not be always regulated by the principles of good taste. Though generally affable, good-humoured, and sprightly in the discharge of his duties, there are occasions when these customary and amiable qualifications give way to temporary irritation. Dr. Graham having a great horror of interruption, and of "sketching" likenesses during the delivery of his lecture, is sometimes ruffled into passion, not by the pencil of "Scotus," but by that of a much more celebrated artist, the well-known Dr. Syntax of Edinburgh. The Doctor (we, of course, mean Syntax) is so singular a personage, that we are induced to turn his own art against himself, and transfer him to our pages. For aught we know, but from his appearance, the Doctor may have been a contemporary of Cullen's, and has had the rare merit of continuing a student all the time, in despite of lectures and examinations which he has heard and undergone

without number. Free by long attendance and purchase to the different courses in the "curriculum," the Doctor is seldom or never absent from the class-rooms of the University. As the bell tolls the hours for lecture, he may be daily seen hurrying down Nicholson Street to the College, with a bundle of note-books or portfolios under his arm, his aged and withering form enveloped in a suit of seedy black; and if the day should demand its protection, a plaid-mantle girded round his waist, which, from the fading tints of its texture, might have served some hardy highlander on the plain of Bannockburn, or wrapped the athletic form of Rob Roy himself. Either the Doctor has by this time appropriated whatever knowledge is to be acquired from university professors, or admonished by a series of fruitless attempts to acquire a legal right to a title which is now conceded him only through the complaisance of his numerous acquaintances, he has given up apparently all idea of profiting by their valuable instructions, his time in the lecture-room being exclusively occupied in transferring the physiognomy, instead of the words of the lecturer, to one of his portable sketch-books, in which are deposited innumerable likenesses of all the Edinburgh professors for perhaps the last half century. In short, the Doctor has relinquished the pursuits of physic for the practice of the painter, and devotes his whole time to pencil, or pen and ink, sketches of the professors of Edinburgh, which it must be admitted he executes with a masterly fidelity to the originals. It might be supposed that one so devoted to his adopted art, and of such extremely inoffensive manners as the Doctor undoubtedly is, would pursue his harmless avocations in the lecture-room, without interruption to the pupil and the professor. It is however almost impossible, for the most zealous student in the acquisition of knowledge, or for the most abstracted lecturer in the discharge of his duties, not to have his attention distracted by the grotesque appearance of the Doctor, as he sits under the glare of a gas-chandelier, with his sketch-book spread out before him, his spectacles imbedded in his grisly and bushy brows, and his pencil sending its industrious ham around the class-room, as he plies it with indefatigable perseverance over a slip of "Bristol Board." Apart from the distraction which so attractive an object must necessarily create in the mind of a speaker engaged in serious avocations, we have some suspicion that Dr. Graham may be jealous of the divided attention of the pupils, who are as much occupied occasionally with the labours of Syntax, as with his own philosophic speculations. His eye, at last,

will be seen to turn on poor Syntax, his brow to lour, and his voice to roughen in the delivery of the most important parts perhaps of his discourse; but true to his favourite pursuits, the Doctor mistaking the rebuke for a new expression in the features of his subject, stares more earnestly at Dr. Graham, until worn out of patience by the gaze of the painter, he exclaims in a paroxysm of indignation, "Have done, sir, I do not like to be caricatured, it is disagreeable to my feelings, and injurious to the interests of the class!" The extreme pains, indeed, which Dr. Graham takes with the instruction of his class, would justify the expression of the disapprobation manifested on those occasions against any interruption of his labours, while the punctiliousness with which he insists on at least an acquaintance with the principles of botany from the graduates of the University of Edinburgh, suggests the propriety of examining the question, whether botany should be *bona fide* an item in the curriculum of the education of physicians. There is nothing indeed more common, than to hear pupils complain of the labour of preparing for an examination in a science which they hold to be totally useless in the practice of their profession. Nor is this complaint confined to students; the *cui bono* of a knowledge of botany, being a common interrogation among persons removed beyond the labour of its acquisition, and exempt from the inconvenience which an ignorance of it might produce at an examination. It is certainly much easier to ask them to point out the precise value of any one of the medical sciences, particularly when the practice of them is as often empirical as it is scientific. It might, for example, be readily asked, Of what use is chemistry or anatomy in the treatment of certain diseases? An analysis of "blue pill," or a knowledge of the structure and relations of the liver, throws no light whatever on the operation of this drug on that viscus. But are chemistry and anatomy to be repudiated from the "curricula" of public instruction, on the strength of this and other isolated facts? Surely not; but it would be as disingenuous to answer, as it is to ask the question in this abstract manner. No doubt Linnæus himself might make a very sorry practitioner at the bed-side of a patient; but we hold that no practitioner can be thoroughly cognizant of the nature of the agents which he employs in the practice of his profession, without a knowledge of botany, which has been too long considered as a mere science of hard names without meaning, among the medical men of Great Britain. Besides its use in the cultivation of medicine, the improvement which it bestows on the mind by the views which it

opens to the industrious student, a knowledge of it is indispensable to the accomplished physiologist, who can never thoroughly understand the laws of animal, without a corresponding acquaintance with those which regulate vegetable life and organization,

SCOTUS.

## ST. THOMAS'S HOSPITAL.

### CLINICAL LECTURE

DELIVERED BY

DR. ELLIOTSON,

Nov. 15, 1830.

#### VARIOUS CASES.

THERE were fourteen cases, Gentlemen, admitted into my wards last Thursday. Among the women were two cases of lepra, which were evidently syphilitic, from the leprous spots being in fact tubercles, and from being very dark. I observed likewise in one of the patients an ulcer of the throat, and in the other an ulcer of the tongue. Both women of course denied having had a syphilitic affection, and having been in the way of contamination. But I am satisfied that you will see the two cases cured speedily by mercury. There was likewise a case of eczema, one of anasarca, and one which appeared to be merely dyspepsia, for there was no organic disease nor gastritis.

*Spasmodic Contraction of the Hand and Foot.*—There was also a very curious case of constant spasmodic contraction of the left foot and hand; the foot is drawn greatly inwards, so that it cannot be straightened at all, and the hand is likewise drawn in, but in an inferior degree. This is exactly the appearance which we observe sometimes in continued fever, and it occasionally remains during the whole of life. You are aware that a state like this arises from no fault in the arm or leg itself, but in the nerves at their union with the brain or marrow, exactly as in hemiplegia, the difference between the two being, that in hemiplegia there is a loss of power, but here an excessive irritation, of the nerves, or brain or marrow, at their union with the brain or marrow. It is not merely that the nerves of motion are alone affected here, the motor nerves of flexion only, the motor nerves of extension being undisturbed. Upon making inquiry, I soon found that there were symptoms in the head and neck. The back of the head and the back of the neck immediately under it were exceedingly painful, and on mak-

ing pressure at the back of the neck immediately below the occipital bone, there was extreme tenderness; the suffering there, indeed, was far greater than at the extremities—the extremities suffered from the violence of the tension caused by the position; but at the back of the neck was suffering from inflammation, extreme tenderness on pressure; and I directed all my attention to the upper part of the spinal marrow and the neighbouring part of the head. The disease, I presume, is in the medulla oblongata, or the cervical portion of the spinal marrow. I ordered the patient to be cupped in the nape of the neck to the extent of a pint, and such was the effect that, the instant the blood was withdrawn, the hand became perfectly straight, and remained so for some time. This was a striking proof that the practice was right, and I have no doubt that by perseverance we shall cure the complaint; for this reason, that it has existed only six days, consequently there is probably no organic affection. This is a more minute division of nervous disease than we usually see. The disease is not only confined to the nerves of motion, but to those nerves of motion that cause the flexion of the muscles.

*Itch.*—Among the men was a case of epilepsy, one of well-marked chronic gastritis, one of deep-seated inflammation above the knee, which does not appear to be rheumatism, one of nervous palpitation without organic disease, which came on from anxiety of mind or some little temporary disturbance of the system, one of acrofulous caries of the thigh and pelvic bones with anasarca, one of itch, which might be easily mistaken, as it is the pustular description of itch, which of course if treated with any thing but sulphur, at least with the ordinary remedies of cutaneous diseases, continues to go on month after month, and yet looks so unlike common itch, that it is sometimes mistaken. I discovered it chiefly by looking at other parts of the body, and finding about the wrists and breasts the well-marked common form of the disease, notwithstanding the large pustules, which had any thing but the appearance of common itch, in other parts. One case was scarlet fever, and one continued fever. As so many cases were admitted, of course a great many had been presented during the preceding week, and among them were six women.

*Continued Fever.*—The first of these of which I purpose speaking, was a case of continued fever, which occurred in one of those poor German females who perambulate the streets, crying “Buy a broom.” She was a native of a village near Frankfort on the Maine. It did not appear to have arisen from contagion, and was cured, as you will see almost every case of continued

fever brought into this hospital, by the most simple means—by enjoining, first, the most perfect cleanliness. I had her thoroughly washed when she came in, and then I employed tepid ablution or cold ablution, whichever was the more agreeable to her, and whenever she felt hot, several times a day. As there was pain in the head, I directed fifteen leeches to be applied to the temples, and these were repeated. In a few days there was tenderness at the pit of the stomach, but her debility was such, that I was afraid to apply leeches again, and therefore ordered a blister to be placed upon the epigastrium. She took hyd. cum creta, grs. v., every four hours. The mouth became slightly tender, her tongue clean, and she was soon convalescent. She was at one time in a state of great debility, but by allowing her milk and two pints of strong beef tea per diem, and combating the local symptoms, the complaint gave way. It is said by some of the French writers, that when there is pain in the epigastrium on pressure, blisters are an improper mode of treatment, that they produce great irritation, and we ought only to apply leeches. I know, however, that where there is such debility that we cannot apply leeches, or when we have applied them frequently, and still something more is requisite, you may have recourse to blisters with great advantage. The only injury arising from blisters, is where they are allowed to take the place of the loss of blood,—when it is necessary that a certain quantity of blood should be taken away, but it is not taken away. In such cases, if you merely apply blisters, you produce great irritation; but if you remove a certain quantity of blood either from the arm or locally, after you have done this once or twice, or more frequently, the time may arrive when blisters will be useful, from the continuance of the symptoms. Sometimes blisters may not be required; but if the irritation continue after you have emptied the part well by means of leeches or general bleeding, you may have recourse to blisters with great advantage. That was the case here; her tenderness was speedily removed by the blister. She recovered so soon, that having been admitted on the 20th of October, she was on the 11th of November presented, and was able to walk home. This is the common treatment adopted by me, and it is so successful, that during the last two years only one patient has died in the hospital under my care of continued fever, and that was a man who was admitted in the advanced period of typhus; his tongue black, and muttering delirium present. Strict attention to cleanliness, cold or tepid ablution or affusion, local bleeding wherever signs of inflammation are present, attention to the bowels, and the moderate exhibition of

mercury. I give calomel, if the bowels will bear it, or the hydrarg. cum creta, and if there be irritation of the intestines, you may check it by moderate quantities of astrin-gents, or opiates, or leeches and blisters to the abdomen, should it be in an inflamma-tory condition.

There was likewise among the women who were presented another case of conti-nued fever, which was treated in nearly the same way. No. 9 in the same ward. The disease was mild, and the local irritation not in the head or abdomen, but in the chest. In cases of fever, if you apply the stethoscope to the chest, you will generally find a slight rattle of the same nature as in bronchitis. Here the seat of the local affection indicated that the local means should be employed at the chest. The pain was not great; there was only a slight soreness. I ordered leeches to the chest, and gave her the hyd. cum creta ten grains, three times a day, the same as in other cases, and ordered her to be kept on slops. There is, perhaps, a danger of increasing the bronchitis if you chill the surface of the body, at least when there is inflammation of the air passages, lungs, or pleura; I have feared to use cold effusion or ablu-tion; and as the heat was inconsider-able, did not have recourse to ablu-tion either warm or cold in this case.

There was likewise the case of pleuritis presented, to which I alluded in a former lecture, which was cured by a good vene-section and leeches, followed by the admi-nistration of a large dose of calomel and opium. There was no relapse, and she went away well.

*Hemiplegia and Paraplegia.*—There was also a case of hemiplegia, much improved under the use of iodine, but which I should be wrong to say had been benefited by the iodine. It is very common in cases of par-alysis, if moderate diet be observed, for the disease to decline, without our having re-course to remedies of any other kind; and I have no doubt that many instances of hemi-plegia thus cease of their own accord, when the cure is ascribed to medicines. After a time congestion ceases, or the effused fluid is absorbed; and if low diet be ob-served, a return of the congestion or effu-sion is often prevented. The absorption will proceed of itself; and if, in the lower orders, these complaints are left alone, they will improve to a certain degree, and then get no worse, or totally disappear. The tincture of iodine has been strongly recom-mended in cases of hemiplegia. It does good, probably, by promoting absorption of effused fluids. In the present case, nothing was observable, but that the woman had lost the use of her right side. No headach, drowsiness, or giddiness, was complained of. I began with ten drops of the tincture,

increasing it gradually to forty, three times a day, and she certainly recovered in a very great degree, and desired to go home. I have not met with many cases in which it has been so successfully employed, and, indeed, wherever there is drowsiness and giddiness, it would appear useless, I should fancy, to employ the iodine. The proper remedies, where there is fulness of the head, is general or local bleeding, a moderate de-gree of purging, a moderate use of mercury, and low diet, great care being taken not to carry these too far. I am sure that many persons are reduced far too low in the treat-ment of hemiplegia. They are suffered to sink so low, that the brain cannot repair the injury it has suffered, and the system gives way. Although antiphlogistic mea-sures are generally best at first, and un-doubtedly demanded, it should always be remembered that there is a danger of carry-ing them too far. If, after general or local bleeding, you keep up a drain from the part, exhibit mercury moderately to lessen congestion and inflammation and promote absorption, it is often necessary to employ means to keep up the strength. Iodine may be at this period frequently useful. Yet I have given it often fruitlessly; and often when persons recovered under its use, I saw no proof that the recovery was not owing to natural processes, or the antiphlogistic means employed in the first instance. Those who study morbid ana-tomy will suspect that it cannot be very generally useful, as sometimes a softening of the substance of the brain, sometimes excessive induration, encysted tumours, fungous and other growths, are frequently discovered to have been the cause of the disease. So also I may remark with re-gard to electricity, which is much recom-mended in paralytic affections; neither it nor strychnine, any more than iodine, can be expected in these cases to be of any service. If it be a case merely of loss of power, or of pressure from effusion, then stimulants will be of use. You will per-haps recollect a case of paraplegia which was six or eight months in William's Ward, where there was pain in the spine. I knew it would be of no use to give either iodine or nux vomica in this case, but I applied setons and the moxa, and kept the patient on a low diet. Willing, however, that he should reap the benefit of these means, if they could be of benefit, I gave him also nux vomica, or the strychnine, for many months, and tried electricity fairly, but without any alteration in the complaint. I have, in fact, failed with the strychnine not only as often as with iodine, but much oftener; where there is softening or induration of the brain, or tumours or morbid growths, it must be useless. There are cases of torpor only,

when strychnine is successful. I have employed it frequently, and nux vomica more frequently, but I cannot say in any case with success, unless the case were one merely of torpor. Accordingly, in palsy of the wrists from lead, I have often thought strychnine of advantage.

*Palsy of the Wrists.*—There was a very good case of paralysis of the wrists from lead in which electricity was employed. The man was in William's Ward; he had been ill a year; the brain was not affected, nor was the spine, but here the chords and extremities of the nerves were torpid, deadened by the poison of the lead; as likewise, no doubt, were the muscles themselves; the hand, in fact, was poisoned. He was 50 years of age, and had been a painter. There had been no internal affection, no colic, but simply the hands had dropped.

Now this is just the sort of case in which I have seen advantage derived from strychnine, and have, indeed, known a cure apparently to result from its use. I ordered the wrists to be electrified every day by shocks, and the strychnine to be given in the dose of one-tenth of a grain, increased to an eighth, three times a day. In this case I am satisfied that it was the electricity, and not the strychnine, from which the benefit was derived, first, from the circumstance that the dose of strychnine was so very small (it was only increased to an eighth), and next, because there were no symptoms of catching and tingling of the parts, which you know are among the effects which strychnine produces; thirdly, finding the cure far speedier than I had ever seen from strychnine, and believing the electricity to be the successful remedy, I suddenly discontinued it, and went on with the electricity, and the cure proceeded just as rapidly as before. He was admitted on the 7th of October, and went out on the 11th of November. He was electrified thoroughly with shocks in the wrists every day. The strychnine was only employed for ten days. He would, in fact, have gone out earlier but for an attack of rheumatism, which came on in his knees and delayed his departure.

*Rheumatism requiring stimulating treatment.*—During the week several cases of rheumatism have been presented, all of them cured, and I will now point out to you the treatment of rheumatism which I have found most successful. Among the women, for example, there was one case of rheumatism admitted which required a stimulating mode of treatment. Jane Davis, aged 22, had been ill four months with rheumatic pains in the joints, which became so bad that at last she was obliged to give up work. Warmth to the parts gave her relief. She had no thirst, dryness of tongue, sweating, heat of surface, nor heat of the parts them-

selves; on the contrary, she complained of coldness of the hands and all the other joints: indeed, coldness all over. The parts affected, she said, were never warm. I ordered her the warm-bath every day, and half a drachm of the *Ra. guaiaci ammoniata* three times a day. She at once mended, and was able to leave the hospital in a week. She required a stimulating treatment, and depletion would have done no good, but might have aggravated the complaint. With regard to the employment of the hot-bath, it is absurd to suppose that any good can be derived from its use where it is had recourse to no oftener than once or twice a week, as many patients employ it. Yet with no more frequent use of it, persons will come and tell you that they have used the warm-bath and found no benefit from it. It ought to be used at least four times a week, and if possible, every day. Some people cannot bear it every day, even if they only stay in a short time, from its producing profuse sweating; but frequently they can bear it when they tell you they cannot, if you use it but moderately warm, and they stay in only a few minutes. In the treatment, however, of cutaneous diseases and rheumatism, it is quite ridiculous for people to employ the hot-bath once or twice a week. Many patients can be gradually brought to use it, not only once, but twice a day, and then derive so much the more benefit. I have seen diseases which had baffled all other means, cured by the patient going into the bath three times a day, and remaining in it an hour each time. This woman had it every day. With respect to the tincture of guaiacum, it may be used in any quantity that will do good. I always think it unjustifiable to give a large dose of medicine if a small one will answer the purpose; and, unless in a violent complaint, I restrict myself to a small dose until I find it fail in doing good, and then I gradually increase it. Half a drachm of ammoniated tincture of guaiacum is a fair dose; some persons, however, will bear a drachm, and some several drachms. There was a man in the hospital last spring, in whose case I found it necessary to increase the dose to two, three, four, five, and then six drachms, and then it answered the purpose fully. You find it mentioned in some books that these large doses are required in many cases, and it is certainly a fact that there is no rule for a dose of this medicine any more than for a dose of another. Many persons will be made sick by such a dose as three drachms; many persons will be purged violently, and others might, for what I know, have gastritis produced; but there are some who will bear it, and who are not cured with less. If this medicine do not produce the good effect you desire, if it do not warm, or warm but

transiently, and yet do not disagree with the stomach or bowels, the dose should be gradually increased. I have never given it in such doses as these, except for the purpose of stimulating the system throughout. It is mentioned by Sir Gilbert Blane in his "Medical Logic," that in one form of acute rheumatism, in persons of a scrofulous disposition, the large dose of half an ounce is very serviceable. I have not tried it, but if it purge the patient well, or sweat him, I can conceive that it may do him more good than it would do him harm by stimulating him; yet I should think that in cases of active rheumatism, as it is a stimulating medicine, if it do not make the patient sweat, or purge him well, there would be considerable danger of its stimulating effects doing him great harm. Still it would be absurd to deny a fact. I find it one of the best stimulating medicines in cases of chronic rheumatism, where the temperature of the patient requires to be increased, and warmth does good. This patient had been ill four months, but by this medicine and the use of the hot-bath, she became well in seven days. This was a rapid cure, but I believe in the account of it there was no deceit.

*Rheumatism requiring Antiphlogistic Treatment.*—The other cases of rheumatism were of an opposite character, and would probably have been injured by such treatment. One case was that of a woman in Mary's Ward, who also had been ill four months, and although it had continued throughout that time, the affection was as active as though she had been ill only four days. Rheumatism is frequently active when it has existed for twelve months, that is to say, the parts are at the end of that time hotter than they ought to be, and heat aggravates their pain, so that if you apply any stimulants you do mischief, but if you employ the common treatment for acute rheumatism, you do them good. Acute and chronic are terms by no means synonymous with active and passive or indolent. In this woman I found some slight affection of the chest. There was palpitation of the heart and some degree of cough, and, therefore, I had recourse in her case to general bleeding. In active rheumatism, however, whether acute or chronic, I very seldom have to resort to general bleeding; never, indeed, unless there be some internal inflammation; for I always find local bleeding answer every purpose. If you take the indication merely from the buffiness of the blood, you will find, if you bleed the patient to ten pints, and there are cases on record in which that quantity has been extracted, the last pint may be buffed as much as the first. This has been mentioned by several authors. So long as the least rheumatic inflammation exists, I know that the blood

may be buffed. I was once accustomed to bleed generally in active rheumatism, but I find that local bleeding, with colchicum or mercury, is quite sufficient, and I never have recourse now to general bleeding, except where, as in the present case, there is internal inflammation. There was inflammation in the internal parts of the chest, and, therefore, I bled the patient in the arm, but had it not been for that, I should either not have bled her at all, or I should have applied leeches to the parts most affected. Sydenham once bled all his patients profusely in acute rheumatism, but finding one recover just as well without venesection, he gave up the practice. The medicine in this case was half a drachm of vinum colchici three times a day. I believe many practitioners make it a rule not to employ vinum colchici, but colchicum itself in powder, or the tincture of the seeds, which may be of equal service. But we fall into the habit of employing particular forms of medicine, and I always employ the common wine. The quantity administered to this patient produced purging, and then she was considerably better. I have sometimes seen colchicum do good in active rheumatism, without any sensible effect beyond that benefit; but, for the most part, I have not seen it beneficial, unless purging were produced. With this treatment, although she said she had been ill four months, she became so well, that though she was only admitted on the 28th of October, she went out on the 11th of November, without, as far as could be seen, any complaint.

There was a case precisely like the last also admitted on the 28th of October, into Jacob's Ward, which is among those now presented. It was one of active rheumatism, and had existed seven weeks. The parts were hot, and the warmer the joints were kept, the more painful they became, so that, indeed, the warmth of the bed rendered the pain ten times worse. Thirty leeches were applied to the joints that were in pain, and he took half a drachm of vinum colchici three times a day. With this simple treatment he got so well, that he went out on the 11th of November, the same day that the woman was presented. There was no deviation in the treatment; these simple remedies were employed, and he went on perfectly well. I see, that just before he went out, the rheumatism, which still remained in a slight degree, changed its character; he had no longer any heat. You will frequently find, that the character of rheumatism will change; you may reduce the heat until you have cold rheumatism; and, again, you may increase it till you have hot rheumatism. I have seen these forms of rheumatism alternate, and have been

obliged to alternate the treatment before the patient was cured.

I need not say, that in those cases where I had recourse to local bleeding, I employed moderate diet; it is right to feed the patients on slops, or things little better. The French reproach us with employing the most violent remedies in the country in acute diseases, so that we nearly kill the patients by bleeding them and giving them calomel, and let them all the while eat beef-steaks and drink porter, and do what they like. There may be men so silly, there are men in every business and in every profession who do not conduct their concerns in the most judicious manner, but I am confident this is not the case with the great majority of practitioners. The same attention is generally paid to diet in this country as in any other part of the world; but in detailing our cases, we certainly do often omit to speak of the diet. We take it for granted that it is known we do not give wine and porter; and from the circumstance, therefore, that we do not say so, the French have imbibed the idea that we never attend to diet at all, but that we just see the patients, write a prescription, and then let them go on as they choose with respect to food. This, I am satisfied, is an unjust observation, if it be made generally; but still there are, doubtless, some who do not pay as much attention to diet in this country as they should. We may, however, reproach some of the French with carrying restriction in diet too far. I am sure that most persons who have seen patients that have been treated by the French, have every now and then met with instances in which starvation had been carried so far, that the patients have been in danger of sinking; but who, by allowing them a moderate quantity of animal food, and, in the same degree, stimulating liquids, have rapidly rallied and got well. If we commit one error now and then, the French commit an opposite error, I will not say every day, but as often as we run to the other extreme. Let those who commit the one fault or the other be blamed, but let us not blame each other generally. Every one should recollect that he does not do his duty, either surgically or medically, unless he lays down rules with respect to diet. There is no great difficulty with regard to these rules. Every one must know that those who write on the digestive organs carry the point much too far. It is sufficient to say, that when a person is in an inflammatory state so as to require bleeding, general or local, or antiphlogistic treatment, that one part of that treatment should generally consist in low diet, in the cutting off of animal food and stimulating liquors, or they should be taken in the lowest possible degree. But with respect to articles of diet

in general, what is said by Dr. Heberden is perfectly true, that beyond the general rules of low and moderate diet and full diet with which every practitioner must be acquainted, every man knows best what agrees with him, and he can ascertain it as well, if not better than the doctor. The object of minute rules is often rather to make an impression on the patient than to lay down any specific plan which will do essential good: *Assa vero, an elixa eligenda sint, olerumve utrum utro sit utilius, modo communi judicio non caret, quam alius quilibet, tutius meliusque deprehendet.* There is a difference between low diet, moderate diet, and full diet; and every practitioner should be very attentive to the quantity, and the nutritious and stimulating quality, of the food which the patient is allowed to take. But excessive nicety in directions is too often affected. *Quomodo sanis, quomodo aegris vivendum sit, medici sæpenumero videntur nimis curiose et subtiliter disputare.*

---

SUBSCRIPTION FOR THE WIDOW AND ORPHANS OF THE LATE DR. NUTTALL.

---

*To the Editor of THE LANCET.*

SIR,—I need not refer you to the Number of THE LANCET, in which you did me the favour to insert my letter relative to the lamented death of Dr. Nuttall. I feel convinced you have not forgotten the offer you then tendered in behalf of his amiable and disconsolate family. Your promptitude in giving my letter a place in your valuable Journal gratified my feelings, but when I read the note which you attached to it, I felt supported and sufficiently authorized in endeavouring to ascertain the state in which the family were left, in order to avail myself of your liberal proposal, or to thank you for the same, and to convince yourself and readers that our fears were ungrounded.

The result of my inquiries is far from pleasing. I regret I cannot conclude by returning you only the sincere thanks of the friends of the deceased, for your sympathy and proffered exertions, and mine for the unexpected assistance you tendered. I say unexpected, because at that moment you had commenced an arduous and expensive undertaking for the benefit of the medical profession. I had heard of the vast sums of money you must risk in the contest for coronership, I was not, therefore, a little surprised, when I found you had volunteered your purse, as well as the use of your pages, to aid the friends of Dr. Nuttall in any object they might have in view for the benefit of his helpless orphans.

You have their thanks and mine, and you merit, not only on this occasion but many others, the applause of every well-thinking medical man, indeed of all mankind. You will do me the favour to omit no part of what I have written; I feel honoured in sounding your praise, and trust you will not allow any feeling of false delicacy to interfere with my request. And now, Sir, to my painful task.

For the benefit of some of your readers who may not possess No. 367 of your Journal for Sept. 11th, 1830, or rather for the benefit of our cause, I beg to refer them to pages 941 and 942 of the same, they will there see how I became acquainted with the late Dr. Nuttall, and why I feel so much interested for his family, also your appendix to my letter, which I shall copy here:—

“Should the friends of the late Dr. Nuttall consider a subscription for his amiable and distressed family desirable, our mite and the use of our pages shall be at their service.—ED. L.”

This unasked-for kindness on your part induced me to inquire more fully into the circumstances of the disconsolate family; having done so, and consulted with some of the late Doctor's friends, I find a subscription is not only deemed desirable by them, but absolutely necessary for the benefit of the five fatherless children. You, as well as your readers, will be convinced of this, when you are put in possession of facts.

Some time prior to the demise of my friend, his affairs had become embarrassed, owing to his having on more than one occasion lent his name to friends who proved treacherous—to the house in which he resided before he lived in Norton Street, remaining untenanted for upwards of two years—to his having contributed to the support of an aged and beloved mother,—and to the tender nature of his heart, which melted at almost every tale of woe, and induced him to alleviate the sufferings of the sick and distressed by pecuniary aid.

My former letter will partly serve to prove this last assertion. I could add many others of a similar nature, indeed I could fill a small volume with anecdotes of his charitable and other virtuous acts, which I have witnessed and heard of. Scarcely a day passes but I see some poor creature who has benefited by his kindness or professional advice, and who laments with genuine tears his departure from this world. Some may think Dr. Nuttall was indiscriminate in his givings. Not so: no man in London ever witnessed more real misery than he—no man's feelings were ever more tried. He has seen disease, starvation, and every misery, combined in one family; he has visited such at night in the severest wea-

ther, all huddled together in a cold desolate room, without a bed to lie upon, a blanket to cover them, or fire to warm their shivering frames. He has felt as every Christian should feel—he has acted as every Christian should act—he has placed fire on their hearths, food in their mouths, and from the dispensary sent medicine to restore the sick member to health. In many cases he has paid for medicines when delay would have proved dangerous. Who is the man that could condemn him—who is the man that would not applaud him?

I trust I have said enough to account for Dr. Nuttall's not leaving riches behind him. He may be blamed for not having made a provision for his family; he endeavoured to do so; he insured his life some years back for five thousand pounds, paid the insurance for a length of time, but through the perfidy of the friends to whom I before alluded, and from other causes, he failed to pay one instalment, and the insurance therefore fell. Some time after, he commenced again for two thousand pounds, which sum, I am happy to say, is safe, and the interest of which is all that is left to support the widow and five of the loveliest children parents ever smiled upon. Their education was their father's greatest care; he spared no labour to improve their minds—he allowed not a moment to pass without imparting to them some useful knowledge—he endeavoured to make them not only good members of society, but was preparing them for a life hereafter. What can supply the loss of such a parent? Can money? no; but it may serve to nourish the seeds he has so carefully sown in such fertile soil. Those who have the will, possess not the power, at least not to the extent which is necessary; I allude to the relations on either side.

The widow is still confined to a sick bed, her recovery is as yet doubtful; the loss of a beloved husband preys upon the mind, and other circumstances combined with bodily affliction, are almost too much for so delicate a frame to combat with.

For the information of some of your readers, I ought to have stated that Dr. Nuttall was one of the physicians to the Westminster Dispensary, Gerrard Street, Soho; that he laboured for the institution fifteen years up to the period of his last illness.

I feel convinced, and it is the opinion of many others, that the incessant toil of attending to the duties of the dispensary, assisted mainly in undermining his constitution, and to hasten his death. I have, on several occasions, seen him out after midnight in all weathers, visiting the sick poor; have walked with him, and felt delighted in offering him my arm, that I might profit by his conversation. Whilst I was in his

company he was never idle; I may say with truth, that his mind and body were constantly at work; indeed, "he was a man, take him for all in all, we ne'er shall look upon his like again." From the long-continued illness of the widow, and from the impossibility of Dr. Nuttall's attending to his professional duties, the little stock of cash he possessed prior to his fatal attack was so nearly exhausted, that the day after his death there was not found sufficient in the house to defray the next day's expenses. A friend, into whose hands was entrusted the arrangement of affairs, from his own purse supplied the deficiency, and paid the funeral expenses. An aunt of the unhappy widow arriving from Scotland, relieved him from a continuance of his voluntary kindness, and up to this moment, a period of nearly three months, the family are indebted to her for support.

The interest arising from the insurance will not be payable till twelve months after the demise of the insured. I am informed six months must elapse before even the claim commences, so that at the end of the year there will be only half a year's interest due amounting to 40*l*. When I first began this letter, it was my intention (wishing to spare the feelings of the widow and her relations) to have named only the orphans of my lamented friend; but having been made acquainted with what I have just stated, your readers will with me conclude, that some pecuniary assistance is even at this moment required.

From what I have heretofore witnessed, I doubt not but the sympathy of the profession, and mankind in general, will enable us soon to lighten the burden of the distressed widow and her praiseworthy relation, and to raise a sufficient sum to continue that which the last parent had so well begun—the education of the children.

We ask not for large sums from the profession, their mite will be gratefully received; but we call upon them to plead our cause, where they know charity to exist. Every medical man has it in his power, in the large circle of his acquaintance, to make known this case. We hope then that each into whose hands your valuable Journal falls, will lend us his aid, that he will become the receiver of subscriptions from his patients and friends, and that he will forward the same to Messrs. Hammersley, Greenwood, and Co., bankers, 69, Pall Mall, or to any of the undermentioned repositories for subscriptions. Three of the late Dr. Nuttall's friends have been fixed on to take the charge of subscriptions, and to dispose of them as circumstances may require.

As often as may be deemed necessary, the money received at the different places will be forwarded by them to the bankers,

No. 379.

and, from time to time, your readers shall be apprised of the success met with, the manner of disposal, &c.

I remain, Sir,

Your very obedient servant,

J. H. TUCKER.

16, Howland Street, Fitzroy Square,  
Nov. 27, 1830.

A book (in which subscribers are requested to write their names, and the amount of donations) will be sent to the following gentlemen, who have consented to receive subscriptions:—

Messrs. Hammersley, Greenwood, and Co.,  
69, Pall Mall.

Mr. Robertson, 34, Gerrard Street, Soho.  
The Rev. Mr. Stevens, 15, Huntley Street,  
Bedford Square.

Mr. Tucker, Surgeon, 16, Howland Street,  
Fitzroy Square.

THE LANCET Office, 210, Strand.  
Messrs. Callow and Wilson, Medical  
Booksellers, Great Windmill Street.

Messrs. Burgess and Hill, Medical Book-  
sellers, 35, Great Windmill Street.

Mr. Highley, Medical Bookseller, 174,  
Fleet Street, and Webb Street, Maze Pond,  
Borough.

Mr. Anderson, Medical Bookseller, 40,  
Smithfield.

Mr. Taylor, 30, Upper Gower Street.

P.S.—Allow me, Sir, to say a few words to your brother EDITORS, whether conductors of medical journals, or of newspapers.

GENTLEMEN,—Having availed myself of the kind offer of the Editor of THE LANCET, namely, the use of his pages for promoting a subscription for the benefit of the orphans of the late Dr. Nuttall, and whose character (intended for those who knew him not) I have but very faintly sketched, I sincerely hope you will likewise grant us, the friends of the deceased, all the assistance you can, and kindly publish to the world our intentions, with respect to the unfortunate widow and orphans.

I am, Gentlemen,

Your obedient servant,

J. H. TUCKER.

16, Howland Street, November 27, 1830.

SUBSCRIPTION.

THE LANCET..... 5*l*. 5*s*. 0*d*.

## THE LANCET.

London, Saturday, December 4, 1830.

THE election for a president to the ROYAL SOCIETY, took place on Tuesday last, when, upon scrutinizing the numbers that had balloted, it was found that there were 119 votes for his Royal Highness the Duke of SUSSEX, and 111 for Mr. HERSCHEL; thus the Fellows of the *Royal Society* have elected a *royal* chairman. Had it been a *scientific* society, the president it has chosen might have found himself in unsuitable company. As this body has lost nearly all pretensions to an elevated character, Mr. HERSCHEL may congratulate himself on not having obtained the chair; for high as is his character, and brilliant as are his attainments, he would have experienced great difficulty in supporting his reputation, pressed upon, as it continually would have been, by such a ponderous weight of ignorance. The Society is rotten to the core. It wants intestines, rather than a head. Taking the Fellows as a body, their character for science is not likely to be injured by the accession of the royal President; nor does the Duke's reputation for scientific accomplishments incur any risk of injury from the proceedings of the Society. Thus far they are happily associated. The Duke of SUSSEX is not without his merits; but if the Society enjoyed a high reputation, and if it were zealously devoted to the cultivation of the abstruse sciences, the election of his Royal Highness to the President's chair would have given us deep regret. As matters stand, however, we think the choice is likely to prove beneficial to the public in more respects than one. To the honour of the medical profession it may be stated that Dr. PROUT, Dr. PEPYS, Dr. SOMERVILLE, Dr. CHAMBERS, Mr. J. H. GREEN, Mr. BRODIE, Mr. C. BELL, Mr. T. BELL, Mr. HERBERT MAYO, and Mr. MANTELL, were among the zealous and open supporters of

Mr. HERSCHEL. This speaks not less for their honesty than their judgment. A writer in *The Times* of Thursday asserts, that the election which took place on Tuesday was not for a President, but for a Member of the Council. Fah!

Mr. CHARLES BELL, it appears, is not a little piqued at his resignation having been so unhesitatingly and unceremoniously received by the Council of the University. Mr. CHARLES BELL had amused himself in this way so long, that his toys had become exceedingly disagreeable to his neighbours. He was not careful of their windows. It may have been very pleasant to Mr. BELL to toss "rissignation" papers two or three times a month to the Council, but such trifling could not fail in the end to prove exceedingly irksome to the objects of the annoyance. Other resignations, we understand, have taken place, and the University is in a fair way of overcoming many heavy difficulties by which it has long been oppressed. We beseech the Council not to act with precipitancy in filling the vacant chairs. The errors already committed on this head, should stand as a salutary caution in their future proceedings; and we implore them to elect by *concours*, by open competition, and not by the secret star-chamber method of deciding by private testimonials. In throwing open the doors to all scientific men of sound moral character, we should witness the brilliant sign that would distinguish this institution from the ancient abodes of ignorance and prejudice. To hundreds of aspiring geniuses it would then appear as the promising, the encouraging, beacon of their brightest hopes. Two or three more false steps in the choice of professors would retard the University for many years.

HOWEVER much the surgeons of the present day may boast of their learning and of their successful labours in the field of medi-

cal science, it cannot be disputed that the respectable ancient Company of "pure" surgeons was very successfully opposed up to the year 1540, by the Company of Barber-surgeons. The barbers had been sufficiently influential to get regularly incorporated so early as 1460, while the "pures" could obtain no separate corporation, but thought themselves fortunate in being united with the Company of Barbers, when the joint association was styled "The Mystery and Commonalty of Barbers and Surgeons of London." Having blooded, shaved, and rooted out combs, clipped hair and legs, most successfully, the College of Physicians became alarmed for their reputation and their profits, and prosecuted the rising "shavers" and "pures" for divers infringements upon the rights of the fellows. The doughty knights of the razor and lancet were not, however, to be intimidated. The keen edges of their weapons proved an over-match for the gold-headed canes. The grand united company prevailed at court, and obtained from JAMES I. a charter, which entrusted to them the examination of all who should practise surgery within three miles of London. This was deemed a severe blow by the College of Physicians; nor was the infliction made less by CHARLES I., who extended the power of the shavers as far as seven miles from London. Thus matters stood until the reign of GEORGE II., when the barbers and bleeders could no longer agree. Their jealousies and disputes were at last so much heightened, that the throats and limbs of many of his Majesty's liege subjects were placed in great jeopardy. The strength of the razors ultimately prevailed, and the broken lancets were compelled, though, it seems, not very unwillingly, to retire from the field of contention; for the "pures" had contrived to obtain many friends at head-quarters, and immediately succeeded in procuring an act, which incorporated them into a distinct company, by the name of "The Master,

Governors, and Commonalty, of the Art and Science of Surgeons of London."

Thus matters remained until the year 1790, when, owing to the death of several of the individuals who constituted the Court of Assistants, it was alleged by the survivors that the Company was dissolved, and they applied to Parliament for a new act, with a view to procure a greater extension of their privileges. The members at large, becoming alarmed at the contemplated attack upon their rights, petitioned against the bill, and, at last, got it thrown out of the Lords, after it had passed the Commons without opposition. Lord THURLOW particularly, and in no very measured terms, denounced the proceedings of the promoters of the bill; he characterised them as fraudulent and infamous, and it was owing to his Lordship's powerful influence, that the petitioners against the bill were successful. This contest took place in 1795 or 1796. In the year 1800, the defeated party, still engaged in their hole-and-corner proceedings, secretly petitioned his Majesty GEORGE III. for a charter to enable them to re-establish the functions they had so long enjoyed under the 18th of GEORGE II. In this application they succeeded. The charter was granted,—that charter by which the College is now governed, and by which the members of the College are still robbed, insulted, and degraded. To show how suited the letter and spirit of this document are to the character and accomplishments of the surgeons of the present day, it is only necessary to state, that this instrument is almost a transcript of the charter which was held by "the Commonalty of Barbers and Surgeons in the year 1500," and—still worse—BY THE COMPANY OF BARBERS INCORPORATED IN 1461! Yes; the present charter of the College of Surgeons in Lincoln's Inn Fields, DIFFERS NOT from that which was GRANTED TO THE BARBERS IN 1461! The managing parties are designated by different names, it is true; thus, "Master" is now denomi-

nated "President," "Governors" are called "Vice-Presidents," and the "Assistants" are styled "Councillors;" but the ordinances for the elections are precisely similar, directing that all vacancies occurring in the Court or Council, shall be filled up by the surviving members, thus precluding the commonalty from taking any part in such vitally important proceedings. The choice depends entirely upon the will of the surviving members of the Council. True to the letter of the barbers' charter, not one word is mentioned on the subject of the *scientific* qualifications of the candidates. Not that we would insinuate that the members of the Council are without their qualifications! Oh, it is a goodly "company;" truly a company of "shavers." That man who would not assist in abrogating such a charter as this, is not only a disgrace to the profession, but an enemy to the whole human race.

#### REUNION OF SEPARATED PARTS.

ALTHOUGH there are several instances on record in which parts, after having been completely separated from the body, have been afterwards reunited with it, we believe their number would be much greater if the possibility of such a union were more generally admitted, and the attempt to produce it more frequently made. The following cases, extracted from the "*Heureberg Clinische Annales*," will therefore, we trust, be read with interest:—

M. D., *ætat* 21, had in a duel a piece of the nose cut off, ten lines in length and seven in thickness, comprising part of the ala and the cartilaginous septum. The fragment fell on the ground, with its raw side turned upwards. It was immediately picked up, washed, and applied to the wound, and kept in this position for about ten minutes with the fingers; after this time it was fixed with sticking-plaster, and the wound repeatedly fomented with an aromatic infusion. On the third day the dressings were removed, and the nose carefully washed with warm aromatic vinegar; it was of reddish-brown colour, and reunion was found to have taken place at all points where the skin had been vertically divided;

a small place only, where the section was horizontal, suppurated slightly. The uniting bandage was again applied, and the aromatic fomentation continued. On the fourth day the epidermis of the separated piece was of livid colour, and it seemed as if reunion was not so complete as had been suspected. The temperature and sensibility of the nose were, however, perfectly natural. The wound was dressed in the same manner as before, and lint dipped in a solution of sublimate was applied to the ulcerated part. On the 6th day the skin began to be detached; the subjacent tissue looked healthy, and was covered with granulations. On the 8th day a small portion of the skin came away, but the loss of substance was soon filled up. After this time no unfavourable symptom occurred, and in about a fortnight cicatrization was completed at all points.

In another case, a young man received in a duel with swords a wound by which a piece of the nose, half an inch in length and breadth, a flap of the upper lip, an inch in length and three lines thick, and, lastly, a part of the under-lip and of the apophysis menti, were chopped off. All these parts had fallen to the ground: the piece of the chin was immediately taken up and fixed in its place by fifteen sutures; the fragment of the nose could not be applied for about twelve minutes, and that of the upper lip was not found; the separated piece of the nose became reunited, excepting one-third, which came away. The wounds of the lips healed with a considerable loss of substance, and were cicatrized on the 46th day.

M. B., *æt* 20, had, in a ruse, a part of the nose, of twelve lines in length and sixteen in breadth, chopped off; the stroke was directed more towards the left side, and the left ala was completely separated; the flap terminated at the upper lip, and adhered to it by means of a pedicle about a line and a half in diameter; there was a profuse hæmorrhage from the left nasal artery, which it was found necessary to tie; the flap, which meanwhile had become quite cold and pale, was then reapplied in its proper place, kept *in situ* by a few sutures and sticking-plaster, and fomented with aromatic wine. Towards the evening the piece of the nose had slightly recovered its temperature, but was still pale and collapsed. On the third day the dressings were cautiously removed, the piece of the nose was of a bluish colour, almost cold and quite collapsed, and the stump of the nose began to be covered with erysipelas. The edges of the wound were dressed with an ointment of camphor and Peruvian balm, and the fomentations were continued. On the 5th reunion had not taken place in any point of the wound, all points of suture had suppurated, and on the 7th the piece of the nose came away whilst

the patient was sneezing. The wounds were healed up after about seven weeks.

B., ætat. 21. of fair complexion, received in a duel a cut across the face, by which part of the tip of the nose, the alæ, and a portion of the septum, were separated; the piece was immediately reapplied, and kept in its place for a few minutes with the fingers, and then by means of a uniting bandage. The skin of the patient was so irritable, that the sticking-plaster caused an erysipelatous inflammation and a papular eruption, notwithstanding which, however, reunion was found to be complete on the third day, yet the separated piece was of a bluish colour, and it was expected that mortification would ensue; the skin became detached on the following day and came away, leaving an unhealthy suppurating surface; under the repeated application of a balsamic ointment, and the solution of sublimate, the ulceration became of a more healthy character, and after a few days the wound began to granulate. The separated piece retained its vitality, and cicatrization was completed on the 10th day.

Besides these four, the above journal contains twelve more cases, all observed by the same practitioner, in most of which reunion proved successful.

# LONDON MEDICAL SOCIETY.

November 8, 1830.

Mr. CALLAWAY in the Chair.

## INFANTILE MARASMUS.

Mr. DENDY this evening read a paper on the pathology and treatment of infantile marasmus.

The study of those morbid affections which occur during the period of infancy is one, said Mr. Dendy, replete with interest. The helpless condition of the patient, the obscurity of the symptoms, the sudden exposure of the frame to the influence of external agents, the abrupt assumption of the duties which belong to the alimentary canal, and extreme susceptibility of the nervous system, are all matters of interest and importance.

Amongst the diseases which are arranged in the infantile nosology, there are few, the causes, symptoms, seat, and treatment of which have excited so great a diversity of opinion as the malady which has been denominated—*macies*—*atrophia lactantium*—*febris infantum remittens*—*hectic fever*—*tabes mesenterica*—*marasmus*. The causes of this diversity may have been various.

The immediate cause of marasmus is inefficient nutrition, arising either from a diminished or suppressed absorption of chyle, or by a deteriorated condition of that fluid which renders it, if absorbed, unfit for its important office in the animal economy. For although irritation of the nervous system may prove fatal of itself, it does so usually by its immediate effects on the brain, or the medulla. If the irritation be more protracted, the functions of the intestinal canal are from this cause deranged. These affections, as well as partial wasting or paralysis, it is not my purpose to treat. A healthy body, especially that of the child, is in a state of constant renovation and increase. The supervention of disease in those organs which perform this important function incapacitates them for their duty; their function is either altered, or suspended, or destroyed.

Granting some absorbing power to other tubes, the grand medium of nutrition is the lacteal apparatus of the intestines. Whatever, therefore, deranges the function or disorganises the structure of the mucous membrane of the alimentary tube, may be considered the exciting cause of marasmus. The chief of these causes are—retention of the meconium—dentition—exposure to cold—the recession of eruptions—deficient or excessive supply of aliment—deleterious food—worms—the poisons of measles, scarlatina, small-pox—of which diseases intestinal irritation and its consequent diarrhœa are the most frequent sequelæ. To this list it may be expected I should add those cases of profuse or increased discharges which are marked usually by wasting, as coryza, leucorrhœa, and perhaps diabetes, but if I admit those it would lead me to digress, as the emaciation attending them is a consequence of almost every disease in infancy. I wish here to confine myself to the abdominal sources of marasmus.

I consider then that there are two conditions of the mucous membrane of the bowels which induce marasmus—simple irritation and inflammation, or muco-enteritis—often a disease into which by neglect simple irritation may be excited, a fact which agrees with the opinion of Dr. Goelis, that the majority of infantile diseases bear an inflammatory character. I do not mean to assert that this diseased action invariably commences in the mucous membrane; many instances have, I doubt not, occurred where idiopathic inflammation of the peritoneum has been the primary disease, extending in the end to the mucous surfaces; although where we have ulcerations, and even fistulous openings at the points where the convolutions of the intestines lie in contact; it will be a difficult task to say in which tunic the disease first commenced. I believe,

however, that peritonitis is marked usually by the adhesive inflammation, and muco-enteritis by the morbid changes I have alluded to above. I am anxious to establish, as far as I can, the proper seat and nature of this distressing disease, because I think that error regarding this circumstance has been productive of frequent unsuccessful practice. The pathologist has been led away from the commencement of the lacteal tubes, by a fancied importance attaching to the mesenteric glands in the function of nutrition, or the tonic or stimulant plan been resorted to when depletory measures have been indicated. Hence wasting of the body has been described by the sweeping term *tubercles mesenterica*, because a suppurating gland has been sometimes discovered on examination. My books had led me also into this error, but experience has often shown me, on the dissection of fatal cases of marasmus, how slight, if any, disease existed in the mesenteric glands—how extensive were the lesions of the mucous and peritoneal coats of the intestines.

The suppuration of mesenteric glands is generally a secondary disease, extending from other tissues; or in the scrophulous enlargement, it may be an ineffectual effort to expel some constitutional taint; or an incapability of resisting that action which, in a vigorous system, and within due limits, is set up to repair or relieve the *vis medicatrix nature*.

I believe that muco-enteritis may often exist as a primary affection, yet it may be considered also as an aggravated form, a consequence of previous irritation; but as the removal of that exciting cause will not effect the subsidence of an established inflammatory action, the distribution of the causes of marasmus into simple irritation and inflammation becomes of the greatest practical value, equal in importance to a knowledge of the seat of excitement.

Irritation may be termed a disorder of function—inflammation that of structure. In this distinction consists the practical importance, which if we disregard, we may on the one hand drain the system of its blood to absolute exhaustion with none but a fatal effect; on the other, we shall neglect those measures without which the same disappointment will follow. I shall, therefore, consider separately, but briefly, these two conditions of the mucous surface. If I have made myself understood, it will be perceived that I presume to endow these varied excitements with the power of producing the two diseases indiscriminately, but the action established on the membrane by the specific excitements—measles, scarlatina, and small-pox—is, similar to themselves, a disease for which nature herself will often

establish the remedy—a salutary, or critical diarrhoea.

*Simple Irritation*.—Is characterised by those symptoms which have been termed mesenteric and infantile remitting fever. It is seldom that the disorder is observed by us in its first stage, the treatment of which is usually confined to the nursery. The child is restless and fretful, the prominent symptom being often simply constipation. To this succeeds a contrary condition of the alimentary canal; the secretion of the mucous surface is increased, the effort of the system, in fact, to dislodge a load from the bowels, and we have mucous diarrhoea established. This is the stage at which the patient is usually presented to us. The evacuations are mucous, slimy, or watery, sometimes of a grass-green mixed with flakes of mucus, and sometimes streaked with blood. Small hard buttons of feculent matter are often evacuated with the mucus, and these are attended by a most painful tenesmus: in the intervals the abdominal pain often ceases entirely, and the child will then suck *freely* and even eagerly, and appear lively. The heat of skin is not much increased, the pulse is accelerated, ranging often above 100, the lips are dry, and there is often an aphthous affection of the lining membrane of the mouth. Gentle pressure on the abdomen will rather soothe than irritate; and the child will even bear deep and firm pressure of the hand without crying,—the expression of complaint indeed, is generally more fretting than crying. This state will soon become aggravated; the diarrhoea and tenesmus will be more constant—often incessant, and prolapsus ani will take place. The child will become pallid—often of a livid complexion; the appetite fails; the pulse becomes less perceptible; the exacerbations of fever more frequent; the emaciation extreme; and in this condition the child will gradually sink.

In these cases dissection will discover to us little morbid change in the abdomen, except, perhaps, a superabundance of flaky mucus, or, in a protracted disorder, a peculiar emptiness of the alimentary tube; the colon will be often distended with gas, and throughout the small intestines numerous *volvuli* are often found. Death then usually occurs from a mere deficiency of absorption; the contents of the bowels being hurried past the mouths of the lacteals with great rapidity; of this condition I might cite numerous examples.

In this disease, however, as in many others, there may be a remote sympathy with other organs, which we are apt to overlook; with the membranes of the brain especially, in which chronic meningitis and ventricular effusion take place, as it will indeed even in cases of extreme irritability,

owing to the quality or quantity of milk from protracted suckling.

*Muco-Enteritis.*—In this disease we have some symptoms in common. It may, however, be distinguished from irritation by a more oppressed though fuller pulse, by greater heat of skin, by a physiognomic expression of suffering, especially about the alæ nasi and the lips, in the early stage by a feeble though shrill cry or scream, in the latter period by a dull moaning. There is a parched condition of the mouth and lips; the head is tossed to and fro; the pupils are much contracted as in meningitis, or dilated as in effusion (febris gastrica, or synochus); the legs are drawn up towards the abdomen, the belly is tumid, and there is pain felt on deep pressure. The absence of constipation will distinguish this, I think, from peritonitis, or at least from idiopathic inflammation of the peritoneum commencing in that membrane. The evacuations, in the advanced stage, are of a very peculiar character, a greyish pulpy mass like chewed paper. If the ear is applied to the belly there is a sound of constant gurgling, obeying the motion of the diaphragm in breathing, differing from the usual sound of peristaltic action. Eventually the pain will be more severe on pressure, and more extensively diffused; the peritoneum has partaken of the disease.

There is an essential difference in the type of fever, in the second form, there are seldom if ever remissions, the local excitement being constant.

On the examination, especially of protracted cases, the abdominal viscera will often be found matted together, so that it is difficult to distinguish them from each other, ulcerated or fistulous openings will be found perforating their coats. Both in the cavity of the abdomen, if that be not obliterated, and in the intestinal tube, pulpy or slimy, or purulent matter will be found. Livid patches are sometimes observed both on the surfaces of the intestines and the skin. The mesenteric glands will sometimes be found enlarged in this stage of the disease, and in a state of suppuration. We have very frequently symptoms which might appear to indicate extensive effusion into the ventricular cavities; it is not so often that we find much evidence of the disease about the brain, except that slight increase of serous secretion which is so commonly found in fatal cases of pneumonia, &c.

In the treatment of these forms of disease I have little to add; my purpose has been rather to establish a discrimination, which, being determined, we shall be easily guided in our practice by the general principles inculcated in our elementary study.

In many cases of simple irritation the removal of the exciting cause will be of itself sufficient to cure the disorder, ere in-

flammation be established. The mere incision of a gum will often appear to be the effect of magic on the child. The event, however, must mainly depend on the degree or duration of the diarrhoea; for if this flux be immoderate, the contents of the bowels will be hurried past the lacteal orifices to the effect of absolute exhaustion. It is, in fact, of natural hypercathartis. With regard to the following exciting causes—retention of meconium, deficient or over-feeding, unwholesome milk, the irritation of dentition, the presence of worms, the remedies must be obvious. During dentition, it is true that acute pain may, by directly influencing the brain and nervous system, exhaust the vital powers; but even here, in almost every case, I have observed diarrhoea has been a concomitant, if not a prominent symptom. In the cases produced by the application of cold, or the superficial cure of cutaneous disease, the re-establishment of free cutaneous transpiration, or the reproduction of the eruption, will be equally beneficial. In general, however, the recovery will be expedited by the exhibition of small doses of hydrarg. cum creta, adding occasionally some aromatic powder, and one or two drops of the liq. opii sedativus at night, and after some days the employment of a mild tonic. The form I would recommend is the following:—

*Ferri sulph. exsicc.*, ʒss;

*Pot. sulph.*, ʒiij;

*Pulv. cascarill.*, ʒss. cap. gr. iv. ad x. b. ter die, and a few drops of acid sulph. aromatic; added to these remedies, a few drops of laudanum should be given in an enema of starch.

A more direct laxative is sometimes necessary even under a state of diarrhoea; for in those cases characterised by cachexia, the removal of a morbid coating, which sometimes accumulates to an excessive degree over the lacteal mouths, constitutes the laxative itself an indirect tonic.

Let me here briefly draw a distinction between the condition of tabes, and the state often consequent on weaning—the child gradually becoming thin, but otherwise not exhibiting symptoms of an unfavourable nature. Such may be, in fact, a natural and healthy change dependent on more solid nutriment, an increase of muscular growth and power, and a diminution of deposition into the adipose membrane.

In speaking of the management of the second form, muco-enteritis, I am more anxious again to draw the attention of the members of this society to the nature of the disease, than to fatigue them with a detail of treatment so plainly indicated. The destructive lesions, demonstrated on dissection, prove either that the disease has not

always been understood, or, if understood, inefficiently treated. It is in the early stages, while the evacuations are mucous or flaky, or of the spinage green, that we may hope to relieve. I believe that when the evacuations assume the appearance of the grey pulp, and are in great quantity, that no treatment will be available; destruction of parts has commenced, the repair of which is beyond the reach of art. In muco-enteritis, from one to four leeches should be applied to the abdomen; the hæmorrhage assisted by the application of a warm bread poultice every half hour, or the child immersed in the warm-bath on the leeches falling off. The food light and mucilaginous.

It is right for me to state that I have examined several cases where the peritoneal coat has been extensively diseased, and the intestines agglutinated without much mark of disease in the mucous membrane. These cases, however, I believe to be not common, but from their protracted duration they would be as likely to exhaust life as any other form of chronic disease.

The pallid or livid complexion of the child in these diseases, has caused pathologists to determine that the symptoms arose from strumous taint of constitution and disease in the mesenteric glands, and hence they have adopted, indiscriminately, the tonic or the cordial treatment in all the stages. This I think an error, the glandular suppuration not being the result of abstract debility, but an effect of destructive inflammation on a texture endowed with deficient vitality, incapable of resisting even slightly increased action.

In some of these cases, although there had been the most striking indications of cerebral effusion, I have found the brain and its membranes of a perfectly healthy appearance.

In conclusion, let me not undervalue the cerebral pathology of infants. Although I consider idiopathic meningitis in children as very rarely occurring, yet from its being so readily induced by remote excitement, I not only always regard cerebral symptoms with great jealousy, but often advise depletion and evaporation from the head, when I suspect such excitement as dentition, or the subsidence of measles or scarlatina, &c., would be likely to induce disease about the brain.

At the conclusion of the paper, Mr. Proctor asked the author if he had not often found the liver morbidly enlarged in this disease.

Mr. DENDY replied, that in consequence of the great relative size of the healthy liver in infancy, he could not answer in the affirmative.

Dr. WHITING agreed with the author in

his division. Irritation and muco-enteritis, were often to be considered as cause and consequence. In the first state he would do little more than rigidly adhere to light diet.

Mr. DENDY concurred with Dr. Whiting as to the value of a judicious dietetic plan in all these diseases, but he thought the exciting causes of the complaint were too often overlooked.

November 15th.

#### ADMINISTRATION OF CORROSIVE SUBLIMATE IN TINCTURE OF BARK.

THE subject of Mr. Dendy's paper was again discussed this evening, but the observations were of too discursive a nature to permit of their being reported with any advantage in the limited space we could afford to them. In the course of the evening the President (Mr. Callaway) spoke of a formula which he said had long been prescribed with the most beneficial results, by Sir Astley Cooper, Dr. Babington, and himself, in *tabes mesenterica*, especially in those chronic affections of the alimentary canal where change of structure had commenced, viz., a grain of the oxymuriate of mercury in an ounce of the tincture of bark, with some other vegetable tincture, the name of which we could not ascertain. A few drops of this were occasionally administered.

An impression seemed to prevail amongst the members, that this mixture was chemically incompatible, and its good, as a *mercurial*, was therefore questioned. One gentleman stated, however, that in a particular case which had come under his observation, he had known salivation result from its operation. Into this circumstance we have instituted an experimental inquiry; and as our observations will, we believe, reconcile the conflicting opinions, we may take this opportunity to state them.

When tincture of galls, considerably diluted with water, is mixed with a minute quantity of corrosive sublimate in solution, a fawn-coloured precipitate occurs, resulting from the formation of a per-gallate of mercury and tannin. A similar effect takes place with the tincture of bark, and proceeds from the operation of the same affinity. This per-gallate of mercury is dissolved, when heated to 98 deg., with either muriatic or acetic acid, a per-muriate or per-acetate being formed, and gallic acid and tannin set free. It will thus readily be understood, that, though chemically incompatible in the phial, the insoluble compound is again decomposed by the acid secretions in the alimentary canal, and that it there operates as corrosive sublimate, or the soluble per-acetate of mercury, as the case may be.

If, however, the corrosive sublimate be

mixed with an *aqueous* preparation of bark, it is reduced to the condition of calomel.

November 22 and 29.

#### BURNS AND SCALDS.

ON the former of the above evenings, Mr. THOMAS, a gentleman who is not a member of the Society, laid before the Society a paper on the nature and treatment of burns and scalds, which was originally written for the "Fothergillian medal," a prize that was offered by the Society last year for the best medical or surgical essay that might be presented within twelve months, by any gentleman not a member. Some irregularity, we believe, occurred to prevent the competition, and the present paper alone was submitted to the members.

The essay, though well drawn up, did not contain anything novel on the treatment of the injuries in question. Its principal object was the recommendation of flour, of which the author, from experience, spoke very highly. A discussion on several points referred to by Mr. Thomas ensued, and was resumed on the following evening, the 29th, but it did not afford any information which is not already well known, nor any views which have not, probably, been already entertained by most of the members of the profession. Almost every variety of treatment obtained a recommendation from the speakers. A vote of thanks was subsequently passed to Mr. Thomas for his communication.

#### WESTMINSTER MEDICAL SOCIETY.

November 27, 1830.

Dr. GRANVILLE in the Chair.

#### ULCERATED URETHRA.

DR. GRANVILLE described a case of ulcerated urethra in the female (communicated to him by Mr. Earle), which is at present under treatment at St. Bartholomew's, and for the cure of which a peculiar contrivance was employed; it consists of a perfectly flexible air-tight tube of gut, covered with India rubber, and filled up with a stop-cock and injecting syringe. The tube is introduced into the vagina and inflated by the piston, until it accommodates itself perfectly to the size of the passage, and exerts a certain degree of pressure on the fistulous opening from the urethra into the vagina. The destroyed portion of the canal is thus, as it were, artificially replaced, the urine flows through its natural passage, and the ulcerated orifice is gradually contracting in size.

On the whole, it is hoped that a permanent cure will be effected.

#### CHOLERA MORBUS.

Dr. STEWART next read a short paper on cholera morbus, evidently intended rather to elicit discussion, than to communicate any peculiar facts or opinions. On the question of the contagious nature of cholera, Dr. Granville remarked, that some of the circumstances connected with the Indian and Russian diseases, were calculated to puzzle both the contagionist and the anti-contagionist. Mr. Bacot was of opinion, that diseases may be both of an endemic and epidemic kind; that cholera morbus may arise from atmospheric causes, and also from specific contagion: in this opinion he was corroborated by his own experience in hospital gangrene, fever, and other diseases, during the peninsular campaign. The Society in general seemed to agree in the great probability of the Russian cholera extending itself to England at no very remote period. Dr. Granville especially was inclined to this opinion.

The only peculiar mode of treatment was recommended by Dr. Webster, who contended that very small doses of opiates were better calculated to assuage irritation of the stomach than large quantities. He usually gave five or ten drops of laudanum, combined with ten grains of the sulphate of magnesia, with certain success. Mr. Evans fully corroborated the efficacy of Dr. Webster's method, and alluded to Mr. Brodie's prescription in the case of Miss Caahin, which he supposed was dictated with a similar intention.

#### ERRATUM.

To the Editor of THE LANCET.

SIR,—In the last Number of your valuable Journal, in the report of the Westminster Medical Society, it is stated that "Mr. Costello said that cases had been lately published by *Spinaldi* in Italy, in which the *secale cornutum* was administered in free doses" in cases of hæmorrhage; I take the liberty to let you know, that *Dr. Spainardi* was the person who employed the remedy, and that he who made this remark, was

Your humble servant,

D. C. NEGRI.

Nov. 30, 1830.

## PROPOSED IMPROVEMENT IN THE CONSTRUCTION OF SPECTACLES.

By MARTIN EVANS, M.D., Teignmouth.

MANY of your readers may be inclined to suppose that the subject of the present letter is misplaced, when inserted in the columns of your invaluable Journal. However, I am disposed to look upon any information which tends to remedy a defect in the organs of our most useful sense, the eyes, as perfectly adapted to them.

For some time past, I have been in the habit of using the doubly-concave eye-glass, commonly employed by young people, and have found that its utility may be very much, indeed wonderfully increased, by fixing it in a particular direction in relation to the eye. The statement for procedure in the experiment may appear obscure without the assistance of a diagram, but I shall endeavour to make myself as intelligible as the nature of the subject admits. That part of the glass which rests at the inner canthus should be fixed as a centre, whilst the part towards the external canthus is directed *forwards* to a degree which varies in different persons. When it reaches this point or focus, the object viewed appears extremely clear, so much so indeed as to justify an assertion of increase in a double ratio. Persons who do not require the aid of glasses cannot appreciate this improvement. Those only whose vision is so far impaired as to need such artificial contrivance will pronounce on its application. My experiments on the doubly-convex glasses of old people, have not been sufficient to bear me out in extending the principle to them; neither have I as yet arrived at a satisfactory rationale of the process; some of your readers, therefore, may be ingenious enough to do so. From the knowledge of this circumstance, I venture to suggest to Opticians a practical improvement in the construction of spectacles. It is the following:—Let the space between the lenses, or that part which rests on the *ossa nasi*, be formed with a *pretty stiff*, horizontal joint in the centre, in order that an obtuse angle could be formed when necessary, the vertex represented by the joint, the sides by those parts of the spectacles which surround the lenses and directed *forwards* to a certain extent as above mentioned. This shape, although at present appearing unhandsome, would by time, and its utility, be reconcilable to our ideas of beauty in figure.

Teignmouth, Devonshire,  
October 25, 1830.

## LONDON HOSPITAL.

To the Editor of THE LANCET.

"Still dipt in verjuice, Walford's angry pen  
And dirty spite, resource of abject men,  
Harmless play o'er his vitiated page,  
Too high we stand to feel his scorn or rage;  
Short is the course his calumny has run  
But long enough to leave him quite undone."  
OLD PLAY.

SIR,—Your correspondent, Mr. Walford, reminds one of a little petulant boy, who when quite vanquished flies to the last resource—*puerile abuse*; and although exuberant in unapt quotations, the torpedo of Burton Crescent must possess more electric matter before the touch of his pen benumbs even the weakest of Mr. Headington's pupils.

My friends' wearing the blue riband savoured of folly, and strongly too, so thinks Mr. Walford; but ere he gave utterance to that thought, should he not have recollected that the pupils' compliment was an emanation of the same feeling which called Mr. Walford forward in your cause? My friend did the best his circumstances allowed, *Mr. Walford could do no more*, and this was folly. How very expressive of respect is this honest confession to Mr. Wakley's cause, and proves that the radiated sense of Mr. Walford is reduced to a small focus indeed.

Poor weak man; in bidding him farewell, we cannot help expressing our obligations for the amusement his letters have afforded, and in return we wish him all the happiness a fallen spirit can attain. We can also assure him that our worthy teacher, Mr. Headington, cares little for the venom of his rage, nor would he sully his dignity even by noticing the mean reptile that has crossed his paths. To the bubbling effervescence of Mr. Walford's malevolent mind he stands

"As the high rock's majestic form  
Frowns on the flood nor feels the storm."

I remain, Sir,

Yours respectfully,

J. RICHARDS.

London Hospital, November 30, 1830.

COLLEGE OF SURGEONS—ACKNOWLEDGED  
AVARICE.

To the Editor of THE LANCET.

SIR,—The author of the letter on "Collegiate Avarice," which appeared in the last Number of your Journal, was surely influenced, in the composition of that letter, by some secret antipathy to the honourable court of which he complained. The question which commenced your correspondent's

examination, should rather be the subject of congratulation than of censure; inasmuch as it virtually admitted, on the part of the College, what has long been supposed to be the true object of their exertions. I admire, Sir, the manliness of that admission; and only regret that the honourable court should have delayed it, until it was no longer necessary for the conviction of either the profession or the public.

I shall avail myself of this opportunity to caution many of your correspondents against the extreme severity and evident ill-nature of their strictures on the College. Such a style is rather calculated to weaken than support the cause which it is intended to serve. It is recorded of Mr. Curran that the most eloquent and most effective of his pleadings was one in which he confined himself to the *mere facts* of his brief, and I am sure that the same mode of attack would be excellently applicable to the conduct of the College-court. The bare mention of their schemes, the simple recital of their regulations, would awaken quite as much contempt as could possibly be given under any circumstances to such an institution. The bitterest eloquence of their opponents cannot censure them more severely than they censure themselves by their own daily conduct!

I am, Sir, with great respect,  
Your faithful servant,

J. C. J.

Church Street, Blackfriars,  
Nov. 29, 1830.

#### ABUSES IN GUY'S HOSPITAL.

To the Editor of THE LANCET.

SIR,—As you have ever stood forward as the supporter of the pupils' rights, I am emboldened to ask the insertion of a few lines in your valuable journal. I am induced to ask what course we are to adopt when we are deprived of those privileges for which we have so dearly paid. Mr. Morgan professes to give his lectures on wounds three times a week, but he gives us sometimes two, and frequently not more than one a week, in consequence of his "being in the country," or "not having his diagrams ready." Why, I would ask, were not the drawings prepared before the 1st of October? Is this, as his colleague expressed it in his introductory lecture, doing his best to make "the short time we have to spend at the seat of learning (oh, dear!) most profitable?" and is it embracing every opportunity of improving us? No; this is Guy's Hospital treatment.

Again, post-mortem examinations, which

take place almost daily, (successful practitioners!) are always *managed* in private; at least they are not publicly announced to the students; so that they are only attended by a favoured few. As these may be deemed liberal regulations by King Harrison and his sycophants, it is right that they should be published, for the benefit of those young gentlemen who may be coming to London, to expend their money in the pursuit of knowledge.

A SURGICAL PUPIL OF GUY'S.

P. S. Mr. Morgan has now deceived us three nights following. Do tell us our remedy.

Nov. 23, 1830.

#### ST. BARTHOLOMEW'S HOSPITAL.

##### TUMOUR OF THE NECK.

THE patient, the subject of this affection, was admitted into Henry's Ward, about four months since, under the care of Mr. Lawrence. There was a hard tumour occupying the extent of the sterno cleido mastoideus, but no discoloration of the surrounding integuments. Nothing particular was done for it until about two months since, when the integuments covering this muscle became inflamed, and Mr. Lawrence then directed the repeated application of leeches, and subsequently the use of the camphorated mercurial liniment. About a month ago an ulcer formed over each extremity of the muscle, and a fortnight afterwards, Mr. Lawrence connected these ulcers by means of an incision through the integuments, by which a yellow inorganic mass, of the length and breadth of the muscle, was exposed, and was supposed to be the sterno mastoid. A portion of it was removed, and exhibited a fibrous appearance. On the following days, portions of this mass, which appeared detached, were removed, and about a week since, his neck and head were attacked by erysipelas, which was treated by antiphlogistic means. During the erysipelatous attack, delirium came on, and for this he was bled from the temporal artery to  $\frac{3}{4}$  x, had his head shaved, and cold lotions applied. When we visited him on Saturday the 20th, the erysipelatous inflammation had disappeared, but the delirium continued, and his nervous system seemed very much depressed. He remained in this state until to-day (Monday the 22nd of November), when he died.

Mr. Lawrence, at his clinical lecture, said that he had examined the body after death, and had found inflammation of the arachnoid membrane of the brain, a small quantity of fluid in the ventricles, and rather more than

usual vascularity of the brain. Nearly the whole of the muscle was of a dirty-yellow colour, disorganised, and scarcely a vestige of healthy structure could be found in it. There was also disease of the liver, but no other morbid appearances could be detected, and there was nothing discovered that might be supposed to have given rise to the disease of the muscle.

#### REPEATED HÆMORRHAGE AFTER AMPUTATION.

In our notice last week of the case of John Reeve, we omitted to date it October the 30th, the day on which we wrote the report. We may now observe that he went on well from that time until the 2d of November, when hæmorrhage again took place. Mr. Vincent was in the hospital, and saw him within five minutes of the recurrence of the bleeding, and found him in a state approaching to syncope. He had lost a very considerable quantity of blood, his countenance was quite pale, pulse scarcely perceptible, and the limb perfectly cold; the bleeding was not so free as it had been, but was still copious; the stump was opened, and the hæmorrhage immediately ceased; his pulse became imperceptible, and it was necessary to give him brandy, and to envelope the entire limb in flannels saturated with very hot water. As soon as his pulse rose a slight oozing of blood took place, and endeavours were made to find the bleeding vessels, but in vain. Mr. Vincent then made an incision in the direction of the popliteal artery, with the intention of tying it; but as no pulsation could be felt in it, this measure was not proceeded with. The fomentations were continued for an hour and a half, and so much spirit was given to him that he became tipsy. The oozing continued; no vessels could be seen bleeding, and Mr. Vincent filled the wound with lint, and left the patient, having directed some saline medicine to be given every four hours. He went on well again until the 8th of November, when hæmorrhage ensued, but to a slight extent only. The wound was opened, no bleeding vessels however could be detected, and it was again filled with lint, and the hæmorrhage ceased. Up to this time he had been allowed meat diet; Mr. Vincent now ordered him a milk diet, and to take the following draught every six hours:—

℞ *Aluminis*, ℥i;  
*Ty. cinchonæ comp.*, ℥i;  
*Infus. ros. comp.*, ℥iiss.

On the 10th bleeding came on again, and was rather profuse. Mr. Earle being in an adjoining ward was called to him, when he found it necessary to give him brandy, and

as soon as the patient had recovered from the syncope, an incision was made, by which the popliteal artery was exposed and immediately secured.

Nov. 30. There has been no repetition of the bleeding, and the patient appears to be proceeding favourably.

#### HOSPICE DE LA PITIE.

##### CANCER OF THE NOSE—EXTIRPATION.

G—, ætat. 32, was admitted in May last, with a carcinomatous affection of the nose; the disease was of about two years' standing, and seemed to extend over the cartilages of the nostrils and the septum, which had degenerated into a large ulcerated tumour. After having watched the case for some time, M. Lisfranc, who was of opinion that it was a case of superficial cancer, performed the following operation:—Two semi-elliptic incisions were made, by which the diseased part was circumscribed; the skin, with the subjacent cellular tissue, which was found to be the principal seat of disease, was dissected off the surface of the cartilages, scraped with a bistoury, and then touched with the nitrate of silver, especially at those parts where the disease did not seem to have been entirely removed by the knife. After a few days, the eschar having come away, healthy granulation began to take place, and cicatrization was completed within a short time.

#### HOPITAL BEAUJON.

##### FRACTURE OF THE NECK OF THE THIGH-BONE AND OF THE OS PUBIS.

A YOUNG girl of robust constitution, but who had of late presented symptoms of mental derangement, threw herself, on the 7th of October, from a window on the second floor. On being taken up, she was found to have a slight wound in the neck, and a violent contusion over the right hip. Twenty-five leeches were immediately applied, and on the next morning she was brought into the hospital. There was much swelling and ecchymosis at the upper and external part of the hip; the patient could not move the thigh, and complained of violent pain whenever it was raised; the limb was not shortened or distorted in any direction, nor could any crepitation be heard on motion. The limb was placed on a double-inclined plane, and the patient ordered to be bled. During the following days delirium acceded, with tenderness of the abdomen and tympanitis, and suppression of the urine and fæces, and

she died on the 14th of October. On examination, the muscles which cover the joint were found much contused and infiltrated with blood; the articular cavity was filled with a thin reddish turbid fluid, and the neck of the thigh-bone, at about three lines from the shaft, was obliquely fractured. The fragments being in close contact with one another, accounts for the absence of distortion after the accident. The cellular tissue of the pelvic cavity round the bladder and rectum was infiltrated with a brownish matter, particularly at the right side, where the horizontal branch of the os pubis was found fractured at the distance of about a line from the spina pubis. The fragments were about three lines distant from each other; the external fragment being drawn upwards and outwards.—*Lanc. Franc.*

## HOPITAL DE LA PITIE.

### LITHOTOMY.

C—, ætat. 60, of a feeble constitution, had, during the last nine years, been labouring under symptoms of stone in the bladder. Being admitted at the hospital under the care of M. Velpeau, lithotripsy had been tried, but without success; the stone being very large, M. Velpeau was rather disposed to perform the high operation. M. Lisfranc, however, declared himself against it, and the lateral operation was accordingly decided upon, and performed on the 21st of October. After the incision in the bladder, the stone was easily grasped, but proved to be so large, that all attempts at extraction failed, and M. Velpeau was obliged to enlarge the wound, first in a lateral direction, and then by dividing the prostate. The forceps being now re-introduced, the stone was again seized, and at last, though not without violent efforts, extracted: it was of an oval form, two inches and a half in its large, and two inches in its small diameter. Contrary to what had been supposed from the previous examination with the sound, no other calculus was felt in the bladder, which was large, but healthy. On the 29th of October the patient was going on favourably; the hypogastric region was neither tense nor tender; the urine still passed through the wound.—*Ibid.*

## HOTEL DIEU.

### OBLITERATION OF THE VAGINA.

ANGEL. ANDRE, ætat. 22, was admitted on the 12th of August with violent colic pain, which she attributed to a stone in the

bladder, but which, on examining the genitals, was found to be caused by the accumulation of the menstrual blood in the uterus, in consequence of the vagina being obliterated. She had been quite well until about three months ago, when, in consequence of great excesses in drinking and debauchery, she was seized with violent inflammation of the genitals, which terminated in gangrene; the extremity of the clitoris, the nymphæ, and part of the large labia, went into mortification; the vagina ulcerated, and, after the inflammation had subsided, was found to be completely obliterated. In other respects the girl was quite well, but, at the time of the menses, the blood accumulated, and caused a sensation of weight and sharp colic pain in the hypogastric region. At the next menstrual period, these symptoms returned with increased violence; the colic pain, the attacks of which curiously enough always began at noon and ceased at about six o'clock in the evening, was very intense, and the patient experienced great difficulty in making water, and passing the stools. It was then only that she applied to a medical practitioner, who advised her to go into the Hôtel-Dieu, where the genitals were found to be in the following state: The large and small labia, as well as the extremity of the clitoris, were entirely wanting; the orifice of the vagina was very small, and terminated at about half an inch in a "cul de sac;" at the left iliac region there was a large tumour, which could also be felt by the finger in the rectum; it was of a globular form, moveable, and exhibited distinct fluctuation, and no doubt was entertained that it was the upper portion of the vagina distended with blood. On the 10th of August the following operation was performed by M. Dupuytren: a long trocar was passed into the contracted orifice of the vagina and plunged into the tumour, and the opening thus made was enlarged in several directions with a bistouri, carried along the canula of the trocar. A large quantity of dark, viscid, inodorous blood was thus evacuated, and the cavity having been washed out by the injection of warm water, a further examination of the parts was made. The parietes of the vagina were found to be adherent to one another for the space of about two inches, beyond which was a very considerable dilatation which had contained the menstrual fluid; the os uteri appeared to be closed. A tube of gum elastic was introduced into the vagina, and the patient went on well for a fortnight, when she was attacked with pneumonia which proved fatal in about nine weeks. It is remarkable that the pain in the chest appeared to be relieved by the removal of the canula and increased by its re-introduction. A similar case is related in a late number

of the *Lancette Française*, by M. Patrix; the patient had, after delivery, been affected with peritonitis and inflammation of the genitals, which terminated in gangrene; a great portion of the external genitals sloughed away, and the vagina became completely obliterated, although every-thing was done to prevent it. By the continued use of lint-tents, however, M. Patrix succeeded in reproducing the former canal; the woman subsequently became pregnant and was safely delivered.

In a case of congenital obliteration of the vagina, which was admitted in 1829, M. Dupuytren evacuated, by the operation, more than three pints of viscous dark-coloured, but inodorous, blood; the patient was twenty-two years of age, and had, according to her statement, felt the first symptoms of menstrual congestion in her fourteenth year. She got perfectly well after the operation. The blood was submitted to chemical analysis by M. Thenard, who convinced himself that it did not contain the least particle of fibrine or serum.—*Lanc. Franç.*

### HOPITAL DE LA CHARITE.

#### EXARTICULATION AT THE SHOULDER-JOINT. —TRANSFUSION OF BLOOD.

C. A. was on the 29th of July brought to the hospital with a gunshot wound at the right shoulder. On examination, the bone having been found to be minutely fractured, exarticulation at the shoulder-joint was immediately decided upon, and performed by M. Roux. No unfavourable symptom occurred after the operation, the wound began to heal up, and had even cicatrised for the greater part, when, on the 25th day, a slight discharge of blood took place from the ununited part of the wound, and was soon followed by real hæmorrhage, so that M. Roux, finding the application of external remedies without any effect, resolved upon tying the subclavian artery below the clavicle, according to Scarpa's method, viz., by interposing a small cylinder of adhesive plaster. The hæmorrhage was thus arrested, and the patient again went on favourably for about a week, at the end of which, however, a new hæmorrhage took place from the wound of the last operation. The usual remedies failed again in arresting the blood, and M. Roux saw himself obliged to tie the artery for a second time above the clavicle; two ligatures were applied, and the artery divided between them. The hæmorrhage was, however, not arrested, and the blood continued to ooze from the wound of the first ligature, at the same time pleuritis began to develop itself; the patient was extremely exhausted with delirium at intervals, and in

a state of the greatest depletion, so that M' Roux decided upon resorting to transfusion as the last resource. At the commencement of the operation there seemed to be a resistance to the blood passing into the vein, but it was soon overcome, and the operator succeeded in injecting about a pint of blood, which, however, could have scarcely reached the heart, when the patient was suddenly seized with a fit of suffocation and died instantly. On examination, several fragments of bone were found in the wound from the amputation, near the origin of the external thoracic artery, where the cylinder of sticking-plaster had been applied; the subclavian was ulcerated, the two other ligatures had not produced any alteration in the vessel. The heart and left subclavian vein contained much coagulated blood; the left lung contained some small abscesses.—*Gaz. Med. de Paris.*

### CHOLERA MORBUS IN RUSSIA.

At the sitting of the Institut National on the 2nd of November, a letter was read from M. Gamba, the French consul at Tiflis, on the commencement of the epidemic which is at present raging in Russia, and seems to threaten all Europe. The disease had shown itself in the autumn of 1829, at Teheran and Casbin, on the frontiers of Persia, and seemed to have been completely checked by the intense cold of the ensuing winter; in the spring of 1830 it broke out again at Tauris and Ghilan, and spreading along the western shore of the Caspian Sea, reached Lankeran, Soliam, Bakou, Dezbeu, and Astrachan, where its progress was for a short time arrested. It soon, however, extended further, and reached Tiflis on the 8th of August. On that day three soldiers of the garrison were seized with it and died within a few hours. It was rapidly propagated throughout the whole town, which was, on the 13th, filled with alarm and confusion, so that every-body fled and took refuge in insulated houses; the bazaars, caravanserais, and all public places, were shut up, and the population of Tiflis thus suddenly decreased from 30,000 to 8000. The poverty of the inhabitants, the intense heat of the season, and, above all, the scarcity of medical practitioners, seem to have contributed towards the extraordinary mortality and rapid propagation of the disease. Of the nine physicians who practise at Tiflis, four died within a short time. On an average, the disease was fatal eight hours after the appearance of the first symptoms, it began with a fit of syncope, which was followed by vomiting and diarrhoea, violent

convulsions, cramps, cold of the whole body and death. Bleeding, calomel, opium, and ether, had been employed without effect. Criminals were ordered to place the dead on litters, and carry them to the place of interment, where they were buried in their clothes. M. Gamba regrets that he cannot communicate any instances of generous devotion, which, he says, is completely wanting in Asia; he reports, on the contrary, a remarkable case of insensibility in a rich merchant, who within five days, lost his wife, mother, brother, and another near relative living with him; he had fled from the house on the first appearance of the disease, and returned within a few days after the decease of his family, not to bewail the dead, but to marry a beautiful young Armenian.

From the 8th of August to the 8th of September 5000 persons died at Tiflis and the neighbourhood. The same number have, according to late communications, perished at Tauris, where the plague had shown itself at the same time, but without its usual destructive character.—From the *Lanc. Franc.* and the *Gaz. Medic.*

## TO CORRESPONDENTS.

COMMUNICATIONS received from Dr. H. C. Field—Mr. Rennie—Mr. T. M. Greenhow—J. S. C.—Dr. G.—Dr. West—Mr. W. R. C. Clark—Mr. R. S. Richardson—Mr. Vaughan—Mr. R. Edwards—Dr. Home—Mr. Samuel Smith—Mr. Richardson—Mr. R. Thornhill—L. G.—Mr. Fergusson—Mr. H. Peter—Mr. Cazenove—Freewill—E. C. D.—Mr. Yates—Mr. J. Hutton—Mr. Nicol—Dr. Frederick—V. V.—Mr. Webster—W. S.—A Surgical Pupil of Guy's—Mr. Clark—Mr. Hamilton—Mr. Cattle—Y. Z.—Mr. Firth—Mr. Dermott—Judge not—Mr. A. Scott—Mr. Baldwin—A Surgeon-Accoucheur—A Reformer—A Medical Pupil—Caustic—A Surgical Radical—Mr. Willson—Mr. Corss—Mr. Thomas Long—A Looker-on—A Friend—Extract from Manchester Advertiser—Mr. Everitt—Mr. Woodham—A University Student—A Hater of Bats—Mr. Fowell—A Bartholomew's Pupil—Mr. Pearson—One of the Rubbed-out—Mr. Green—Dr. Nagle—Dr. Duval—Obstetricus, London, 4—Obstetricus, Stepney, 1—Obstetricus, York, 1—Argus.

*A Surgeon-Accoucheur.* The Apothecaries' Act does not give the Company any control over surgeons or accoucheurs.

*Inquirer.* Eighteen persons petitioned for the charter which was granted by George III.

*A Subscriber.* We contend that a regu-

larly-educated medical man, whether physician or surgeon, can prescribe and dispense his own prescriptions; but curiously enough, according to the terms of the Apothecaries' Act, a member of the College of Surgeons cannot dispense the prescription of a legally authorized physician without subjecting himself to a penalty of 20*l.* The druggist is liable to no such penalty. Such is the blessed state of medical law. If a *single* writer in the medical journals of that day had understood the subject, the Apothecaries' Act could not have passed the Legislature.

*A Reformer* is referred to the foregoing reply. He stands in little danger; but the judges of the Common Pleas decided, in the case of *Allison v. Haydon*, that a surgeon could not recover for medicines which he had prescribed and administered in a medical case. Typhus fever, in that instance, was the medical case for which the surgeon had attended.

*Lex.* A Charter cannot repeal an Act of Parliament. The 18th Geo. II was not repealed, although the Surgeons' Company failed to comply with its ordinances. It is one of the royal prerogatives to restore corporate privileges that may fall into disuse. The Charter of Geo. III is a mere repetition of the 18th Geo. II, but the dignified term of "College" was then given to the Company.

*An Enemy to Humbug*, in noticing an inflated paragraph which appeared in *The Times* at the beginning of November, relating to Oxford, entitled "University Intelligence," trusts that no such delusive statements will prevent Englishmen from visiting the continental universities. He says, "When the library of the College of Physicians shall be alike accessible to all its members, and to the profession at large (for this College is the monopoly of Cambridge and Oxford), and when these Colleges shall, in the liberal current of the times, have opened their doors to the public in general, for a trifling pecuniary consideration, then the professors will be *known*, and men can appreciate their *worth*."

2. The west-end practitioner was probably correct in his statement. Puncturing the pustules in small-pox to prevent disfigurement, has been practised with much success.

*A Medical Pupil.* The opportunities for medical studies in America are not equal to those of France. In the schools of London there are many American students.

*A Constant Reader* states, "that he has served nearly three years to a chemist and druggist, has attended two courses of surgical and clinical lectures, and can read a prescription well, but that the gentleman to whom he is apprenticed will not allow him

to dispense." The case of our correspondent is, certainly, very peculiar, as the complaints of ninety-nine apprentices out of every hundred are directly opposed to his. Until we are in possession of the whole of the facts, we cannot prescribe a remedy. He must refer to his indentures, the conditions of which, each subscribing party is bound by law strictly to fulfil.

*A Looker-on.* The writer displays much sound sense in his denunciations of non-medical coroners. The Harrogate Coroner, in the case of Mr. Williams, in neglecting to have the body opened, failed to discharge his duty, though the attorney would not have been a whit the wiser, whatever might have been the appearances. We are decidedly of opinion that the arsenical solution was not the cause of death.

The notice forwarded by *Mr. J. Green* would be charged at the Stamp Office as an advertisement.

We are of opinion that those practitioners who are sufficiently bold and liberal to publish interesting cases, with a view to add to our stores of knowledge, should not be subjected to the castigations of anonymous critics. Of course we do not mean to be understood as declaring that all anonymous criticisms are objectionable, but it is not manly to conceal the arm which points the "finger of scorn."

*A Turnpike Man* could become a governor by paying the fee. There is election for governors at that hospital.

*A. R. K.* Thanks; it may prove of service.

The medicines prescribed by *W. S.* are in common use, and the effects produced by them in the case of *J. D.* were not unusual. Nevertheless, the treatment was judicious, and the result fortunate.

*Mr. Martin Van Butchell* resides in Broad Street, Golden Square. He is a regularly-educated surgeon, and has been recommended by *Sir Astley Cooper* in cases of diseased rectum.

*Mr. E. Campbell.* The operation of tying the carotid, by *Mr. Brodie*, in consequence of hæmorrhage after the abstraction of a tooth, was performed in 1817. The details of the case may be found in the eighth volume of the *Medico-Chirurgical Transactions*, page 224.

*A Country Practitioner* reminds us, that the Apothecaries' Company have awarded prizes to students for their acquirements in botany. The occurrence had escaped our notice, and it certainly is not a very important one. Is it a company of herbalists? If they award any prizes at all, why do they not award them for attainments in the higher branches of medical knowledge? Botany, as it is now studied by medical pupils, is almost extra-profes-

sional, and little better than a waste of valuable time. Let the Company award public examinations to the students. The hints contained in the concluding part of the letter of our friend at Yeovil, will not be forgotten.

*Mr. Lightbody*, of Glasgow, has sent us an account of some cases of rheumatism and internal inflammation, which were successfully treated by the warm bath. The particulars are not sufficiently interesting for publication.

*Reporter.* The Goose Egg next week.

*Inquirer, Anti-Quack*, and others. The petition and affidavit have been forwarded to the Lords of the Treasury, but the solicitor, *Mr. Henson*, informs us that we may not receive their reply for some length of time. For the information of our correspondents, we will give some particulars of the account in our next Number.

## BOOKS RECEIVED.

*The Phrenological Journal* to Dec. 1830.

*Science without a Head*; or, the Royal Society dissected. By One of the 687 F.R.S.'s. London, Nov. 1830. Ridgway, pp. 122.

*Selections from Gregory's "Conspectus Medicinæ Theoreticæ," and Celsus "de Medicinâ,"* containing the first Ten Chapters of Gregory, and the First and Third Books of Celsus; the parts fixed upon by the Court for the Examination of Candidates. For the use of Medical Students. By *S. F. Leach*. London, Highley, 1830, pp. 293.

*A Grammatical Introduction to the London Pharmacopœia and Preface.* By *S. F. Leach*. 2nd edit. London, 1828, pp. 180.

*A New Mode of Ventilating Hospitals, Ships, Prisons, &c.,* being an efficient method of Destroying Contagion. By *George Hawthorne, M.D.* London, Longman, 1830. 18mo, pp. 84.

Parts 1, 2, 3, of *Illustrations of Mr. S. Cooper's Surgical Dictionary*, published monthly. Four Lithographic Plates, with Descriptions and References in each No. London, Longman, 1830, 8vo.

*Some Observations on Fumigating and other Baths, with a Summary of Cases treated by J. Green, M.R.C.S.* London, 1830. pp. 67.

*Underwood's Celsus* to Part 10.

# THE LANCET.

VOL. I.]

LONDON, SATURDAY, DECEMBER 11.

[1830-31.]

*Elements of Pathology, and Practice of Physic.* By JOHN MACKINTOSH, M.D., &c. &c. Vol. II. Edinburgh; Carfrae and Son: London; Longman, 1830. 8vo. pp. 467.

ALTHOUGH the volume before us contains evidence of great merit, yet we cannot bestow upon it so high a commendation as we did on its predecessor. Many parts of it indeed are in every respect equal to the contents of the first volume, and alike instructive to the student and creditable to the author; but others bear evident marks of haste or carelessness, and appear to be composed rather from the statements of others than his own experience, even, indeed, where the disease in question must have frequently come under his notice.

The first three chapters on the diseases of the brain and spinal chord, are excellent in every respect except the arrangement, apoplexy and insanity being placed among the latter, or, at least, in the same chapter with them, and separate from the other diseases of the brain. This is, however, of comparatively little consequence, and the account of these obscure and complicated diseases is certainly much better than is to be found in any English work of the kind.

When speaking of the functions of the brain, the author forcibly combats the theory of Dr. Abercrombie, that the quantity of blood in that organ is the same in every state of the circulation, observing,—

“Were Dr. Abercrombie’s hypothesis correct, the circulation in the head, and consequently the functions of the brain, ought not to be materially affected by position; it ought to be all the same, whether the body were supported upon the crown of the head, or on the tuberosities of the ischia. In a practical point of view, then, both experience and common sense loudly rebel at the

bare idea of such notions as those entertained by this ingenious author; for if it were wished to subdue a true inflammatory action in the arterial system of the brain, a vein must not on any account be opened, and more particularly the jugular, because, by emptying the venous system within the skull, or doing any thing which has a tendency to empty it, as a matter of course it must follow, that the quantum of blood in the arteries will be increased in the same ratio, because the vessels of the brain must always contain the same quantity,—if there be too little in the veins, a proportional accumulation must take place in the arteries. Upon the same hypothesis, the converse must also hold good, viz. that when there is great accumulation of blood in the veins of the head, acute action ought to be an impossibility; and the most effectual method of extinguishing inflammation in the brain, would be to place ligatures on the jugulars, or by some other means to impede the return of blood from the head. Cupping, leeching, and the application of ice to the head, ought also upon this principle to be injurious rather than beneficial, and the head and shoulders should be placed in a dependent rather than an elevated position. In conducting this important critical examination, I have not availed myself of the arguments which could be fairly drawn from the experiments of Drs. Carson and Barry, by which it would appear that the heart exerts a *sucking* as well as a *propelling* power, and according to which Dr. Abercrombie would have still greater difficulties to contend with; neither have I taken advantage of certain anatomical facts respecting the cavities in the brain—the free communication between the brain and the bony canal which contains the spinal marrow, nor of the serous fluid which is known to exist in and about the brain and spinal marrow, and which is found on dissection to vary so much in appearance and in quantity.”—pp. 19, 20.

He is not, however, so happy in his objections to another proposition of the same writer, viz., that the heart does not exercise through the arteries any material pressure on the brain, and the case which he

adduces of the bursting of an aneurism within the skull, and the consequent breaking down of the substance of the brain, does not appear to us to bear at all upon the point in question, for under such circumstances, the force of the heart would be very much increased by the extension of the surface of the compressing fluid. We do not deem it desirable to enter into the details either pathological or therapeutical, but we cannot refrain from quoting, at length, for our pages will be well occupied with them, the admirable observations on acute hydrocephalus, and the very just and forcible arguments against the view adopted by Dr. Monro, in his morbid anatomy of the brain, in reference to the nature of this disease. We recommend them to the perusal of those who think with this author, that the effusion in the disease in question depends, not on inflammation, but on debility.

"The only point of inquiry which it is necessary to pursue is, What is the cause of the effusion? Is it the product of inflammation? The best pathologists of the present day, consider it as proceeding for the most part from inflammatory action of the membranes of the brain; but at the same time there can be no doubt that a serous effusion is frequently the consequence of any cause obstructing, or even retarding, the circulation in the head. Thus it is believed to be occasioned by venous engorgement; and dissection affords us positive proof that it is often owing to obstructions in the great venous channels in the head. Others allege that hydrocephalus is produced by debility. This is a pathological question of the utmost practical importance, because the remedies will be depletory in a certain stage of the disease, according to the one view, and the opposite in all the stages according to the other. In order to place the subject in a clear point of view, I shall take the liberty of offering a few criticisms upon the work of Professor Monro,\* because it is the last published work upholding views which I conceive to be erroneous. At page 101, Dr. Monro states, that before subscribing to the hypothesis, that the effusion in hydrocephalus is owing to some degree of inflammatory action, 'it is necessary to inquire whether this disease usually occurs in persons who are disposed to inflammatory disorders at or near the meridian of life, when the human body is most liable to suffer from inflammatory diseases. With regard to the first of these points it may be

observed, that hydrocephalus is so rare after puberty, when the constitution is most liable to inflammatory disorders, that Cullen and other writers of eminence have described it as being peculiar only to infancy. That the disease is rather to be imputed to debility, follows from the well-known fact, that hydrocephalus is frequently a disease which may be traced to bad nursing, improper food, dentition, the sequel of the most tedious and debilitating disorders, as whooping-cough and scarlatina.'

"Cullen's authority is a most unlucky one to quote in the present day for the true pathology of any disease, and more particularly of any disease of the brain. In the work of this author, there are only two pages and seven lines devoted to a detail of the symptoms, causes, pathology, and treatment, of all the inflammatory affections of the brain and its membranes; and all that he has said respecting hydrocephalus is comprised in three lines, in the shape of an erroneous definition! It is a fact, however, that children, particularly those under two or three years of age, are peculiarly liable to inflammation of the brain, from several causes:—1st, From the wonderful changes which take place in the circulation early in life; 2d, The large size of the head at that period in proportion to the rest of the body; 3d, The change the brain undergoes in appearance and consistency; 4th, the great activity of the circulation, and the high state of irritability of the nervous system at that period of life; 5th, Difficult dentition, which perpetually excites a determination of blood towards the head. Besides these causes, accounting for the frequency of the disease, something must be said respecting its fatality in infants. Children cannot tell their feelings, nor direct the attention of practitioners to the seat of the disease. When they are fretful or peevish, it is too often attributed to bad temper, to the state of the bowels, or to the irritation of the gums from the advancement of teeth; and the disease in the brain, as has already been shown, often advances in the most insidious manner, till convulsions or coma take place; and even the latter symptoms, although observed in its progress, is too often overlooked until the patients become insensible and perfectly comatose. Bad nursing and improper food, upon which Dr. Monro has laid so much stress in proof of his own views, certainly tend to produce debility; but children badly nursed, insufficiently clothed, who are allowed to remain wet, and receive improper food into the stomach, are far more liable to inflammation, ending in ulceration of the bowels; at all events, they will be more liable than healthy children to irregular determination of blood, and, from want of vigour in the constitu-

\* Entitled the Morbid Anatomy of the Brain, 1827.

tion, venous congestion takes place, and the vessels of the head suffer, and the effusion may take place as a consequence; or sub-acute inflammatory action will be lighted up in the brain. The experienced eye of a careful observer will be able, in general, to detect the disease in the brain, although it is not announced by symptoms so violent, or of such high-toned character, as Dr. Monro seems to expect should be produced, if actual inflammation had taken place. That venous congestion of the vessels of the head terminating in effusion, and that inflammation of the membranes of the brain, should sometimes take place in hooping-cough and scarlatina, which Dr. Monro designates as debilitating disorders, is not to be wondered at, if the reader will study nature, or refer to the pathological descriptions given of these diseases in their proper places in the first volume of this work.

“ Dr. Monro next asserts, that if hydrocephalus were an inflammatory disease, it ought, like inflammation of the lungs, and other inflammatory complaints, to be more prevalent in robust men, during the period of life when the human frame is most prone to other inflammations. Dr. Monro might have known that the period of life at which inflammatory complaints most frequently occur, is in infancy and childhood; and that for one inflammatory fever or inflammation of the lungs, or of any other organ, in robust men during the prime of life, we meet with at least fifty in infancy and childhood.

“ Dr. Monro makes an erroneous statement respecting the opinions of two distinguished French pathologists. ‘ If it be supposed (says Dr. M.), that hydrocephalus is always connected with inflammation of the brain; and that inflammation gives rise to the *softening* of that organ, which is the favourite opinion of Lallemand, Rostan, and others; in that case the brain should be found *invariably* in a softened state, which is not consonant to my observations.’ But I have already shown that modern pathologists do not assert that the effusion is *always* caused by inflammation; it is sometimes produced by venous congestion, and by any mechanical cause impeding the circulation. Neither Lallemand nor Rostan attributes the softened state of the brain to inflammation of the *membranes*, which Dr. Monro appears to confound with inflammation of the substance of the brain, and who has also attributed to Rostan an opinion *quite contrary* to that which Rostan actually maintains. At page 104 of his work already quoted, he explicitly states, that although softening is occasionally produced by inflammation of the brain, yet that it sometimes takes place unconnected with inflammation, and is a peculiar degenera-

tion, which has its own signs and proper characters.

“ At page 103, Dr. Monro further urges, that ‘ If inflammation of the brain had given rise to this species of hydrocephalus (acute), the attack of the disease should be sudden and well-marked, and its course rapid, like to that of phrenitis; whereas the origin of the disease is generally not well-marked; indeed, so much so, as often to escape the notice of the parent, and even that of the experienced physician.’ And he further states, that ‘ It is admitted, even by those who impute hydrocephalus to an inflammation of the brain, that the symptoms of phrenitis are well-marked, whereas those of hydrocephalus are often very obscure.’ It has already been shown how very insidious inflammatory affections of the brain are, even in adults, they cannot be more so in young subjects; but the reader shall see what Cullen himself says on phrenitis in his ‘ Outlines,’ at page 103. ‘ Many of the symptoms by which this disease (phrenitis) is most commonly judged to be present, have appeared, when from certain considerations it was presumed, and even from dissection it appeared, that there had been no internal inflammation; and, on the other hand, dissections have shown that the brain had been inflamed, when few of the peculiar symptoms of frenzy had before appeared.’ And Dr. Monro concludes, that if acute hydrocephalus be owing to an inflammatory state of the brain, ‘ there ought to be no distinction as to the symptoms, origin, progress, and consequences, of phrenitis and hydrocephalus.’ To make the statement still stronger, he quotes Cullen’s definition of phrenitis, and then states with great self-complacency, that ‘ the symptoms of this species of hydrocephalus do not correspond with the above definition.’ My readers will find Cullen’s definition in a previous page, where it has been shown to be erroneous; and if any further proof is wanting to show its absurdity, it may be easily obtained at the bed-side, or from Dr. Abercrombie’s work on the brain.

“ ‘ One of the most striking features of inflammation of the brain (says Dr. Monro, at page 104) is the state of the pulse; but that character is also wanting in hydrocephalus; for the state of the pulse is *widely* different from that of a person afflicted by apoplexy or inflammation of the brain. It is not full as in the former, or *hard* as in the latter. It is no doubt quick, as in other diseases which are the effect of debility. Besides, no author, who has described the symptoms of phrenitis, has stated that the pulse becomes slower some time after the commencement of the disorder.’ It is almost unnecessary to comment upon the erroneous statements made

in these passages; but this opportunity may be taken to mention, that Morgagni has clearly shown the great varieties of the pulse in acute diseases; and there are few practitioners of the present day, who are not well acquainted with the varieties of the pulse in cases of head affections. Dr. Abercrombie, in giving a general view of the symptoms which indicate inflammatory affections within the head in adults, makes the following observation at page 12:—'The pulse is about the natural standard or below it, frequently about 60.' And again:—'The pulse having continued from 70 to 80 through the whole course of the disease.' After alluding, at page 14, to the circumstance of the pulse becoming slower sometime after the commencement of the disease, he observes—'As the pulse falls, the patient is disposed to sleep—this is perhaps considered as favourable; it falls to the natural standard, he then sleeps almost constantly, and in another day this sleep terminates in coma. The pulse then begins to rise again; it rises to extreme frequency, and in a few days more the patient dies.'

"Is it not a curious circumstance, that Cullen, in the seventy lines, which is all that he has written on inflammatory affections of the brain, does not notice the state of the pulse, neither does he mention it in his definition?"

"At page 110, Dr. Monro tries to force an invariable connexion between hydrocephalus and dropsy, *both depending on debility*; now, if this were true, children ought to be very liable to dropsical affections in other parts of the body, which is decidedly not the case; but, nevertheless, looking pathologically at these affections, there is a strong analogy. Dropsy sometimes arises from inflammation; so does hydrocephalus. Dropsy sometimes arises from morbid alterations in the structure of the heart; so does hydrocephalus. Dropsy is sometimes produced by disease of the lungs, and particularly bronchitis; so is hydrocephalus. Dropsy in the belly frequently depends on diseases of the liver impeding the circulation; so does hydrocephalus occasionally depend on obstructions in the venous system of the head. Dropsy sometimes depends on diseases of the kidneys; so does hydrocephalus. Lastly, dropsy is sometimes cured by bleeding; so is hydrocephalus!"

"I feel persuaded that this subject has been pursued far enough, perhaps my readers may think too far; but its importance must be kept in recollection, as well as the talents of the author, and the reputation he has long since acquired as a morbid anatomist."

We have already complained of the arrangement, and perhaps some further objec-

tion might be made to the placing of tetanus, hydrophobia, chorea, and the other diseases generally denominated nervous, under the diseases of the spinal chord; but all these affections are certainly in some way connected with the state of the centres of the nervous system, and Dr. Mackintosh has stated nothing which can possibly lead to an erroneous opinion as to their seat or nature; we must, however, except the section on chorea from our general commendation, the treatment proposed for this disease being very imperfect and unsatisfactory. It is stated to "consist in keeping the bowels regularly open, by means of mild but frequently repeated laxative medicines, never allowing a day to pass without producing at least two alvine evacuations;" although the author has just before observed, that the "opinion broached by Dr. Hamilton, senior, that cholera depends on a collection of feculent matter in the bowels, is decidedly erroneous." Though some other remedies are slightly alluded to, the carbonate of iron, which has been productive of such marked benefit in the hands of Dr. Elliotson and some other practitioners, is not even mentioned.

From the section on insanity, which, though brief, contains much valuable information and just reasoning, we cannot refrain from quoting the following observations, which do not, however, belong to the author, but are taken from an unpublished paper by Dr. A. Coombe:—

"The *symptoms* indicative of insanity consist of deranged cerebral functions and local phenomena. Every sense, every nervous function, and every faculty of the mind, may be involved in the disease or not, and hence indescribable variety. The *true standard is the patient's own natural character*, and not that of the physician or of philosophy. A person, from excess of development in one part of the brain, may be eccentric and singular in his mental manifestations, and yet his mental health may be entire. Before we can say he is mad, we must be able to show a departure from his *habitual state*, which he is incapable of controlling."

There is little to notice in the chapters on the diseases of the eye and ear, or on those of the skin; the observations on erysipelas, which is treated of at considerable length, are, however, well deserving of attention. This cutaneous affection the author regards not as a peculiar and idiopathic disease, but

as only "symptomatic of some internal affection, which may be a disorder of function, or one proceeding from structural lesion of some internal organ," as "an inflammation produced by one of those salutary efforts of the constitution, by which disease is sometimes removed or translated from one tissue to another; in this instance, from an internal organ, the functions of which are more immediately necessary to life, to the skin, which has a less important part to act in the animal economy."

With this view of the subject we entirely coincide, and we are satisfied that its adoption must lead to a more rational treatment of the disease, or rather diseases in question,\* the more striking, but less important phenomena of which have hitherto, by the majority of practitioners, been too exclusively attended to. A similar opinion is entertained by the author as to the pathology of gout, as may be seen from the following extract, and certainly the arguments which he has adduced against the idiopathic nature of erysipelas, will apply with nearly equal force to this disease also, however unreasonable it may appear, to some practitioners, to regard the local inflammation as a mere symptom, as a phenomenon of secondary importance:—

"According to the views which I have taken of gout, I would regard it simply as an inflammation of the affected part, produced by an effort of the constitution to remove disease from internal parts to the surface of the body; and therefore the inflammation of the toe is not to be regarded as a disease, but only as the occasional symptom of a disease, which may be one either of function or of structure. This is proved by taking a retrospective view of the causes of gout and the marks of constitutional disturbance, which always precede the inflammation of the part, by the production of a great increase of internal suffering, sometimes of death, from the sudden recession of the external inflammation, and by the universal belief of all who have either seen the disease or experienced its sufferings, that a gouty paroxysm clears the system of something which had been acting injuriously upon it for some time previously."

It is hardly necessary for us to speak of the treatment of gout which is recommended by Dr. Mackintosh; our readers will

readily perceive, from the foregoing extract, that it is not of a specific kind, but rests upon general principles. We shall, therefore, only extract his observations upon the remedy which has of late been particularly employed in this complaint.

"The colchicum autumnale has been highly recommended during the paroxysms of gout, and has been used with the best effects, not only in alleviating the immediate sufferings of the patient, but in breaking the severity of the disease; it has, however, no claim to the title of a specific. There is considerable difference of opinion among practical men, as to which preparation of colchicum is the most efficacious; some recommend the powder of the bulb; others, that of the seed: many prefer the wine of the seed; while others extol the acetic preparation. I have used all the preparations, but find a saturated infusion of the seeds in wine to answer better than any I have happened to meet with. It is to be exhibited, according to the age and constitution, in doses of from twenty to a hundred and twenty drops, conjoined either with the same quantity of tincture of hyosciamus, or with a half, or even a third part of the sedative solution of opium, which I find to answer better than laudanum. In some cases, when the stomach is exceedingly irritable, and when the colchicum cannot be retained, I frequently apply leeches, or a blister, to the epigastric region, and exhibit a pill with two, three, or four grains of calomel, and two of opium. In treating a case of gout with colchicum, I by no means trust to it alone, as if it were a specific, but also attend carefully to the state of the bowels, and allay local inflammation in the same manner as if colchicum were not employed."

In the account of the diseases of the uterine organs there are too many surgical details, while several points connected with the medical treatment are either omitted or too slightly noticed; there are, however, some valuable remarks on amenorrhœa and dysmenorrhœa, the latter of which is stated to be not unfrequently dependent on a circumstance which we do not remember to have seen mentioned by any other writer, viz., narrowness of the os uteri. Fifteen cases have occurred to the author in which this condition existed, and in all a cure was effected by the gradual dilatation of the part with metallic bougies, although "none of the women operated upon had suffered for a shorter period than two years, some for three or four, and others for ten."

\* We do not here mean to include the diffuse inflammation of the cellular tissue, which is much more a local disease than true erysipelas.

It will certainly, therefore, be worth while to make an examination in reference to this point, in all obstinate cases of the disease which have resisted the usual remedies.

We have now probably said enough to show the nature and value of the book ; and while we regret the unequal execution and imperfections of certain parts of it, we may safely state, that altogether the work is one of the best, if not the best, of the kind, and will seldom disappoint the student, or the practitioner, who may refer to it for information.

## ST. THOMAS'S HOSPITAL.

### CLINICAL LECTURE

DELIVERED BY

DR. ELLIOTSON,

Nov. 22, 1830.

#### VARIOUS CASES.

THERE were nine cases admitted, gentlemen, last Thursday, under my care ; three women and six men. Among the women was a slight case of anasarca ; one of a variety of affections, at the bottom of which seemed to be leucorrhœa ; and one of a considerable tumour in the abdomen. This tumour was moveable, reached above the umbilicus, and branched out into lobes ; it was unattended with pain, and could be traced down into the pelvis. I could not trace it lower on one side than on the other, and, on examining *per vaginam*, I discovered the os uteri and the neck of the uterus in their proper situations, and perfectly healthy. I could discover no disease of the womb, nor could I feel the tumour : it was not so deep down on either side as to allow it to be felt in the vagina by the finger, although by pressing the abdomen the os uteri could be forced down. It is very likely to be a diseased ovarium ; but upon its true character I do not feel myself at present authorised to give a decided opinion. Of the cases admitted amongst the men, was a case of disease of the heart, in which indeed not only the heart, but the lungs and the liver also, were diseased, but the heart principally ; a case of pericarditis and organically diseased heart ; a case of chronic inflammation both of the bronchiæ and of the stomach,—of bronchitis and gastritis ; a case of bronchitis which was attended with general dropsy,—anasarca ; a case of pleuritis ; a case of pure bronchitis, without any dropsy ;

and a case of gout. One of the cases presented was that of abscess of the glands at the angle of the jaw, which was treated at first by cold applications and leeches ; but in spite of these suppuration took place, and the abscess was opened, though to no great amount. By these means the suppuration was greatly limited, and I am satisfied that the steady application of cold to enlarged and inflamed glands is one of the most effectual modes of treating them.

#### DROPSY.

The only case possessing any interest was one of severe general dropsy, which was cured ; and that certainly was one of very considerable interest. It occurred in a girl named Maria Sedgwick, ætat. 14, admitted on the 14th of October. She was of delicate habit, had light hair, a fair and very fine skin, and ruddy complexion. After the disease was removed, the redness in the cheeks remained, so that this was her natural colour. It appeared that she had been the subject of ague at different times for the last three years, and that about three months before her admission her belly had become swelled, and not long afterwards her legs ; there had also been cough for about a month, but she had no pain in any part of the chest. When I saw her she was swollen from head to foot, but the abdomen was particularly swelled. The right eye was quite closed on account of the swelling of the face, and the left nearly so. The whole of the abdomen was tender on pressure, and the respiration was quick when she lay on her back, but *that*, in all probability, arose from the tenderness of the abdomen. She had, besides this, diarrhœa attended by griping. Between the great distension of the abdomen by fluid, and its tenderness, it was impossible for me to ascertain whether there was any enlargement or induration of the liver or of the spleen ; nor indeed could I ascertain whether any particular organs were inflamed. The case appeared a very bad one, for there was, besides intense general dropsy, anasarca, and ascites, and extreme tenderness of the whole abdomen, a great feebleness of the pulse ; it was quick, but exceedingly feeble. It was very possible too that she might have great organic disease, as she had suffered from ague. The indication of treatment, however, was of course, in the first instance, to subdue the inflammatory state of the peritoneum. I dreaded the application even of leeches, in consequence of the great smallness and feebleness of the pulse ; I ventured to put on twelve, and after their removal I covered the part with a constant bran poultice. Mere smallness of the pulse, had it been also solid, would have been no counter-indication to free bleeding, but it was extremely soft and

feeble. The leeches relieved the tenderness of the abdomen considerably; but the pulse the next day was so much the weaker, and I therefore could not think of applying them a second time. Still she felt better. I ordered her at the same time with the leeches, three grains of hydrarg. c. creta and the sixth of a grain of opium every four hours, making eighteen grains of hydrarg. c. creta and one grain of opium in the twenty-four hours. It was necessary to give her this form of mercury on account of the diarrhoea, for any other would only have irritated the intestines, and increased the purging; and it was necessary even to guard it with opium, which, too, independently of the mercury, would have been proper, on account of the diarrhoea. I gave her this mercury on account of the inflammatory state of the peritoneum,—on account of the dropsy being evidently of an inflammatory nature. I gave her no diuretics. The treatment evidently was to consist in the removal of the inflammatory state of the peritoneum, and in checking the diarrhoea; for had the latter continued, she most probably would have suffered from it considerably, and perhaps have sunk. Yet it would have been wrong to have stopped the diarrhoea suddenly, for the cessation of secretion of the inner membrane of the intestines might have increased the secretion by the peritoneal coat. I have known ascites produced by a sudden cessation of diarrhoea. The diarrhoea was partially checked, and the tenderness and tension of the abdomen were diminished on the very next day. The motions that had occurred were serous, thin, copious, and very offensive. She vomited two or three times the second day after breakfast, and the pulse was scarcely perceptible, yet she did not feel herself weaker. On the 16th (the third day) she felt much better; there was no pain on pressure on any part of the abdomen, still less were there tension and tumefaction; the vomiting had not returned; the bowels had only been evacuated twice in the last twenty-four hours; the pulse had become more distinct; the motions, however, which had occurred were copious and watery, but were now yellowish; the quantity of urine was increased, and she slept very well. The treatment was not altered during the whole time that I had her under my care. The leeches of course were not applied again, but the hydrarg. c. creta, and likewise the opium, were continued in exactly the same doses for three weeks. Without doing anything more than this, she gradually became perfectly well; the abdomen subsided to its proper size; the tenderness never returned; the pulse became gradually slower and stronger; the anasarca disappeared from every part of the body, and she very soon

left her bed, and appeared in perfect health. I was then able to examine the abdomen, and I found no enlargement of any organ;—no enlargement nor any induration could be discovered in any organ whatever. The case was a very striking one, and, doubtless, many who saw her thought she would die; I had very great apprehensions myself, but under the simple treatment the result was as I have mentioned. She was presented on the 18th of November. Till the 19th of October I allowed her only milk, gruel, arrow-root, and weak broth; but from that time she had half a mutton-chop daily, and this she continued to take till she went out. Now, however simple this treatment was, I am convinced that any other would have destroyed her. Had I given her common stimulants or tonics, or full diet, or had I given her stimulating diuretics, I should most probably have induced excessive irritation of the mucous membrane of the stomach and intestines—I should have suppressed the urine altogether, have increased the peritonitis, and destroyed her. I have no doubt that had she taken squilla and spirit of nitric ether, and been allowed wine, she would presently have sunk. The case was one of inflammatory dropsy, the inflammation being chiefly seated in the peritoneum, and attended with great debility. Had there been no such debility, I should not have been contented with leeches, but should have bled her well from the arm; and if I had applied leeches, I should have done so very freely. I should also not have given her even weak broth, but confined her to slops—to barley-water and tea.

You are of course well aware that many cases of dropsy are exactly of this description. Dropsies, in my lectures on the practice of medicine, I endeavoured to generalize with many other affections: with fluxes, for example,—discharges from the mucous membrane; with hæmorrhages of all kinds, whether from mucous membranes or not, and with various organic diseases. I stated that these occurrences might be inflammatory, or that they might be free from an inflammatory state; that they are all to be diminished very much, and many of them cured, simply by the usual treatment of inflammation, or, indeed, that mode of treatment may be exceedingly improper. This is most strikingly exemplified in the discharges from the various mucous membranes, very many of which may be cured by simple bleeding, general or local, and starving, while others require stimuli to the part itself, or general stimuli and tonics. Dropsy sometimes arises, therefore, from an inflammatory state; but it is to be remembered that it sometimes also arises from an opposite condition of the system. When persons are bled to excess they be-

come dropsical,—not in that instance from inflammation, but from debility. When persons are starved, their legs are observed to swell; they have hollowness of the eyes, extreme contraction of all the features, but their ancles are enlarged. Frequently, too, dropsy arises from an obstruction to the return of the lymph, or if the blood in the veins be impeded, and, in the latter case, from the great distension that is produced, the blood-vessels ease themselves by pouring forth fluid into the serous or cellular membranes. Hæmorrhage will sometimes arise from the same cause: it is not uncommon in diseases of the heart, in which the blood is obstructed, for hæmorrhage to occur from the alimentary canal, hæmorrhage which speedily proves fatal. Sometimes dropsy arises without our being well able to explain its origin. When there is disease of the kidney, it is common for dropsy to occur; one can hardly, however, see why it should be so, unless it arise from the quantity of urine being diminished, and the secretions of the cellular and serous membranes making up for the deficiency. Yet frequently there is here no deficiency of urine; we hardly see why, in disease of some other viscera, there should be dropsy, unless from the cachectic state induced in the whole system. It is very common in disease of the womb for a female to become anasarca, even when there has been no great flooding, and it is likewise common in diseases of the spleen and the liver for the same thing to occur. You might suppose, *a priori*, that there is an obstruction to the blood in these instances, but such a supposition would often be unfounded. Obstruction in the liver and spleen ought rather to induce diarrhœa, or hæmorrhage from the mucous membrane of the alimentary canal. In the case of disease in the kidney, at least, obstruction will not explain it. We cannot explain why the whole body falls into a state of dropsy, unless it be from the whole system becoming cachectic through the renal disease, or a general depraved state of the habit, in which the disease of the kidney is a part only. If the kidney be organically affected, or have great congestion of blood, or an inflammatory state, I believe the urine is generally albuminous; but, on the other hand, I do not think that the circumstance of the urine being albuminous is a proof that the kidney is in this state, at least in a state of organic disease; because I have seen so many persons cured of dropsy, and restored to perfect health, who had albuminous urine; and if the kidney had been originally diseased, we can hardly suppose that that would have been the case; nor could congestion, and inflammation of the kidney, be supposed, because there were no signs of such affections. I have continually seen albuminous urine in cases of dropsy

without any reason, first or last, to suspect disease of the kidney, and I have seen the dropsy completely cured. I think, therefore, that although it is possible that in disease of the kidney, and in congestion of that organ, the urine may generally be albuminous, the converse cannot be said, viz., that if the urine be albuminous we must necessarily conclude that the kidney is in these diseased conditions. When the disease, however, is of the nature that it was in this case, that is, when it is inflammatory, there are sure to be general marks of inflammation, or marks of inflammation of a particular part. I should not have supposed here that there had been a general inflammatory state of the system, for the pulse was exceedingly weak, but there was decidedly inflammation in one part, that is, of the peritoneum.

When dropsy is of an inflammatory nature, you will generally see fullness about the head, or an inflammatory state of the chest, or an inflammatory state of the abdomen, and frequently we have all of these three parts in an inflammatory state. You frequently see the head, from its fullness, become oppressed; the patient complains of drowsiness, or a tightness of the forehead, as though it were bound with hoops, giddiness, or headach; or if you desire him to make a deep inspiration, you find soreness of the chest, and on listening at the parietes you discover a rattle; or if you examine the abdomen you find tenderness some-where there. These symptoms are sometimes inconsiderable; but you will generally perceive inflammatory affection either of the head, chest, or abdomen: perhaps the patient will not mention them spontaneously, and therefore it is necessary that you should inquire after them. There was a case admitted a fortnight ago precisely of this character, that of William Harden, *ætat.* 42, who was admitted on the 4th of November. He had been ill three weeks, and it was found that he had headach and drowsiness, and also dyspœa, cough, soreness of the front of the chest internally, and sonorous rattle. These two parts, then, were affected, the head and the chest. Not that the inflammation was sufficient to cause dropsy in them; that was out of the question; but in the inflammatory state of the system, these particularly suffered. He had anasarca, at least œdema, as high as the hips, and the urine was not found to be albuminous. He was bled to the extent of a pint, and purged with supertartrate of potash; the blood was not found to be buffy. He was again bled to the same extent, when the urine was found albuminous and the blood buffy. He is steadily improving, and the swelling is now no higher than the ancles.

This leads me to consider the question of treating the disease antiphlogistically or not. If the patient have been in perfect health, and suddenly seized with dropsy, you may presume that it is of an inflammatory nature; you will, however, satisfy yourselves of this, by ascertaining whether the complaint arose from cold; whether it arose just as inflammation does every day from the application of cold, especially when united with moisture, and when the body is overheated. Almost all these cases may be traced to this circumstance. Another mark is, that the swelling begins in the face, or occurs as early in the face as elsewhere, the face being particularly exposed to a change of temperature. You will find, in the great majority of instances, that inflammatory anasarca begins in the face, or at least that part swells as early as any other. Another circumstance is, that the pulse will justify you in bleeding. Perhaps the pulse will be full and strong, but whether it is so or not, you may have reason, from the circumstances that I have mentioned, to consider the case to be inflammatory; although the pulse will not *indicate* bleeding, it will *justify* that measure. Observation of the pulse is often very important, and though it will not lead you to resort to bleeding, yet knowing that the symptoms indicate the loss of blood, it may justify you in abstracting blood. Such was the case with this man. In the instance of the girl, I did not infer the propriety of bleeding from the nature of the cause of the complaint. She was too weak to give an account of the origin of her disease, neither could I learn whether it began in the face, and the pulse would certainly have disinclined me from bleeding; but I found decided inflammation of one part of the body, such as made me desirous of abstracting blood by one mode or other, and if there had been no dropsy, if there had been no effusion at all, the case would have required the same treatment. You therefore see that you may *suspect* the inflammatory nature of the case from its being acute, from its beginning in the face, the patient having been previously in good health, and the pulse indicating anything but debility; and, I may add, from the circumstance of the urine not being diminished at all, or, rather, being actually increased; for in this sort of dropsy the urine, so far from being diminished, is not only in general of its natural amount, but is sometimes increased. You may be *sure* of the propriety of treating the dropsy as inflammatory, either by finding the pulse really of that nature—strong, quick, and full—a pulse that would lead you to bleed, whatever might be the disease; or, in other cases, not from a history of the disease—not from any peculiar state of the face or the

urine, nor from the state of the pulse—but you may infer the propriety of treating them antiphlogistically from the existence and severity of some local inflammation, which itself alone, without any dropsy, would point out the propriety of antiphlogistic treatment. That was the case with this girl. In the man's case there was not so much local inflammation, as to make bleeding at all advisable, but he had been previously in good health; his pulse was fuller than that of the girl's; and these two circumstances proved that there must be an inflammatory state of the system, though short of important inflammation in any one part. The treatment was equally successful in both cases.

We have been informed by a writer, that the state of the urine is a sure guide to the propriety of bleeding. We have been told that the quantity and firmness of the coagulum of the albumen of the urine are usually proportionate to the marks of inflammation. It is not asserted that the presence of albumen can only occur where there is inflammation, but it is acknowledged that in an opposite state, where there is great weakness of constitution, where bark will cure the disease, albumen may appear in the urine. It is said, however, that when the albumen in the urine is of considerable quantity and firmness, making a firm coagulum on the application of heat, that there are, usually, proportionate to this, marks of inflammation, and that a correct guide to venesection will be found in the firmness, copiousness, and early appearance, of an albuminous coagulum in the urine.

Now I am perfectly satisfied that this is incorrect. In the man's case there was no early appearance of albumen. When the urine was first examined, there was no albumen in it, and the albumen did not appear till one venesection had taken place, which venesection had been of great benefit to him. Neither, indeed, did the buffiness of the blood occur till after the first bleeding. Then, as to firmness, the albumen did not coagulate into a solid mass, but merely formed a number of flocculi throughout the fluid. I have certainly seen many cases where there was no albumen at all in the urine during the whole of the disease, and yet bleeding was indicated, and positively cured the patient. Although I have very seldom seen the albumen form a firm coagulum in the urine, yet I have seen instances out of number which have yielded entirely to venesection. I therefore do not place reliance on the state of the urine, but I place my reliance for the propriety of bleeding upon the history of the disease, upon the state of the pulse, as to whether this will justify it or not, and upon the presence of local inflammation. It is proper, how-

ever, to say that the writer to whom I have alluded, allows that the limits of venesection will be ascertained from the state of the blood and the relief of the symptoms, as well as from the improvement of the urine. Nevertheless he mentions the fact, that firmness, copiousness, and early appearance of albumen in the urine, is the sure indication of venesection. As I should not hesitate on the one hand, to bleed in the treatment of dropsy, whether there was any albumen in the urine or not (from having continually cured the disease by bleeding, both when there has been no albumen, and also when the albumen that was present formed no firm coagulum), so, on the other hand, I must say, that I have seen the urine full of albumen, I will not say firm albumen, where venesection was a measure quite out of the question. I speak decidedly on this point, because I have made it a matter of considerable observation. I feel that I have good grounds when I state, that in dropsy it is always right to ascertain whether the phlogistic diathesis is present, and to look out for local inflammation. If you do this, I am satisfied that, without an examination of the quality of the urine, without knowing whether it contain albumen or not, you will never be mistaken as to the treatment to be adopted. I gave this girl no diuretics; she took mercury, which I gave on account of the peritonitis, and she took opium to check the diarrhoea; but she took no other medicine whatever, and yet all the secretions came round. The effusion into the cellular membrane and the peritoneum, both arose from an inflammatory state, and completely subsided when that state ceased.

#### HYPERTROPHY OF THE LEFT VENTRICLE OF THE HEART—EXTENSIVE OSSIFICATION.

There have been no *post-mortem* examinations, Gentlemen, this week, but a friend of mine in the country has been so kind as to send me a heart, which he took out of an old man, which furnishes a very fine specimen of cardiac disease. I have not seen it before. It has been opened during lecture by Mr. Norblad (the curator of the Museum), and it is an instance of extreme state of disease.

I will begin with the right side of the heart: there appears to be no disease here. You are aware that the right side of the heart is much less frequently diseased than the left. Disease of the left side is a hundred fold more frequent. However, the left ventricle exhibits a terrible, or a beautiful—just as you please to speak, whether as pathologists or not—specimen of disease. In the first place there is immense hypertrophy of that ventricle; the walls are nearly as

thick again as they should be; the cavity is about the natural size, or if there be any alteration, it is slightly diminished; then there is most extensive ossification all over the sides of its two openings: the left side they are one mass of disease all round. The ring of the mitral valve is one rugged circular mass of bone. The curtain of the valve is free, and the opening natural. Continuous with this is the ossification of the aortic valves. All three are bony; the sacs of them look as if distended by pieces of walnut, and the opening is reduced to a mere three-cornered chink. This man had really a hard heart—a stony heart. If we go on, however, we shall find still more bone. The bony matter extends even to the orifice of the vessels of the neck. The aorta has many large collections of rugged bone upon its inner surface. The bony matter is deposited originally, I believe, under the lining matter of the inner coat; the inner coat cracks, and the bone is then exposed, so that the blood runs over the bare bone. The blood could have experienced no difficulty in passing from the left auricle to the left ventricle, but had extreme difficulty in escaping from the left ventricle into the aorta. Thus the efforts required of the left ventricle are sufficient to account for its extreme hypertrophy, the heart, or any one muscular part of the heart, growing large, like any voluntary muscle, by exertion. You will sometimes, however, see the left ventricle very much hypertrophied, when there has been no obstruction to the course of the blood, and no disease of the aorta.

When we see the present kind of ossification occur in old people, it does not appear to be the result of inflammation, but of a degeneration of structure. In old age there is a general tendency to induration without any marks of inflammation, and when we observe bone, as in the present instance, all that we can say is, that the parts have had a tendency to secrete bone. In young persons these transformations are frequently the result of inflammation. They commence generally with inflammation; inflammation leads to induration, induration to the formation of cartilage, and the cartilage subsequently becomes bone. In old age the change appears generally to be entirely independent of inflammation.

I cannot tell what peculiar symptoms were present in this case, as I believe that the region of the heart was not examined by the ear. If my memory be correct, the letter which I received states that the subject was nearly eighty years of age; that within the last seven years he had walked very great distances, and died apparently of old age, no particular disease having appeared, except dropsy, just before the last.

I think if the chest had been listened to, a strong bellows sound would have been heard, with, or almost immediately before, the pulse, on account of the difficulty the blood had in getting out of the left ventricle into the aorta. Without the narrowness of the aortic opening, the immense thick left ventricle would have driven the blood most impetuously to all parts; it would have given an immense pulse, produced dyspnoea, and perhaps caused apoplexy, hæmorrhage, and dropsy, from forcible distension of the arteries; and without the immense hypertrophy, the narrowness of the mouth of the aorta would have caused such obstruction that there would have been a most feeble pulse, and extreme dyspnoea, hæmorrhage and dropsy, from the obstruction of blood in the lungs and the whole venous system. The absence of inconvenience to the patient till just before death, may be thus explained, and also by the, probably, very slow and proportionate progress of the several organic changes.

---

ON THE NATURE OF  
SCROFULA,

AND ON A METHOD OF TREATING SCROFULOUS  
ULCERATIONS OF THE NECK.

By G. D. DERMOTT, M.R.C.S.

SCROFULA, I believe, is *chronic inflammation* attacking a system predisposed by debility or derangement of health to that disease, and more frequently the absorbent part of that system. The *exciting causes* being those agents which operate upon the absorbent system more especially, or upon other parts which happen to be particularly subjected to the influence of some of these agents, on account of their position or function.

We know that some of these exciting causes are bad and undigested food in the primæ viæ, acting as a source of irritation to the mesenteric glands and absorbents; the influence of cold and moisture of the lungs, and upon the absorbent system, and mechanical injuries of the joints.

Some of my reasons for believing that scrofula is only chronic inflammation existing in certain structures, are those that follow:—

The *predisposition* both to chronic inflammation and scrofula may be created or increased by any cause which weakens the system generally, lessening thereby the supply of healthy nutriment, and impairing the tone of the system or the *vis medicatrix*; or by a cause which deranges a leading function or

function of the body, when nature's healthy harmony of action is broken,\* and she is easily led astray into disordered or diseased action. This disordered state frequently shows itself locally in the form of chronic inflammation in the viscous or part most debilitated or deranged, and most exposed to the (perhaps slight) exciting cause; hence the three grand steps of many diseases are, first, general disordered state of the system; second, chronic inflammation; third, morbid alteration of structure.

Chronic inflammation and scrofula are both tedious. First, on account of the slight degree of vascularity of many of the structures attacked by chronic inflammation (especially when existing in many parts where it bears the name scrofula), so that the parts are slow in changing their action from diseased to healthy, and slow, therefore, in undergoing the process of renovation. Secondly, because the habit, by the debility or predisposition of the frame's action, is not only morbidly susceptible to the causes *exciting*—i. e., is predisposed to *take on* the disease (scrofula or chronic inflammation), but having once commenced with it, to *continue* it; and this, in a ratio to the increasing debility produced by the continued action or impression of such a chronic inflammation (with its probably associated suppuration) upon the system; for, in a ratio to the increasing debility produced by the continued excitement of the disease, so is the general health, or gradually impaired strength, less capable of bearing up under that excitement; and hence on this account, and perhaps by the disease, from its seat locally impairing some leading function of the body (whether this disease be called merely chronic inflammation, or whether custom brings it under the name of scrofula), the *vis medicatrix* or vital power gives way to the ravages of the disease.

It makes no difference whether this debility is congenital, whether it be acquired by such causes as climate or irregularity of living; whether it be temporary debility produced by temporary causes, or even depression of the powers of the body produced by mental depression, for any-thing that brings the system below its natural standard of action, debilitates the agency of life in it, and makes that system morbidly suscep-

---

\* I would call the *vis medicatrix*, or the proximate cause of organic action, *organic instinct*; it is by this that there is such a consent of action existing between living parts as long as they continue in health, which almost seems to amount to cerebral sense; the seat of organic sense and of organic action (instinct) being in the nerves, the processes of the base of the brain, or, in fact, in the whole of the nervous system; the unity of action and sense existing in the system, depending upon the numerous connexions or continuities of substance which exist between the nerves.

tible to chronic inflammation, and which will be produced upon the application of an exciting cause, as in cases of chronic inflammation of the liver, chronic curvaturæ with tubercles in the lungs constituting phthisis, and generally supposed to be scrofulous, chronic inflammation of the absorbent glands called scrofula, and chronic inflammation in any other part of the body where exciting causes have happened more especially to operate.

In scrofula the effects are not only the same as in chronic inflammation constitutionally, but locally; for in inflammation of two contiguous membranes we have them glued together by a deposition of coagulable lymph; or pus is produced between them from their surfaces; in inflammation of cellular structure we have pus produced in it, and its cells glutted with coagulable lymph; in chronic inflammation of membranes, we have a thickening of them produced by a deposition of coagulable lymph in their substance; in chronic inflammation of the liver we have a deposition of coagulable lymph in its substance, and with it, frequently, a secretion of pus: on the other hand, in chronic inflammation of absorbent glands usually termed scrofulous, the local effects are precisely the same—an abundant deposition of coagulable lymph and suppuration; and what are scrofulous tubercles in the lungs, but probably small glands loaded in the same way? At all events, coagulable lymph is the grand constituent of their substance; and in diseased joints (white swellings) there are also the same two effects of inflammation, suppuration and deposition of coagulable lymph. Thus in scrofula we see all the common effects of chronic inflammation, and these merely, viz., a production of pus and coagulable lymph, with a depression and gradual exhaustion of the powers of the system. If these effects are to be accounted for upon the principle of supposing scrofula chronic inflammation, what right have we to suppose it a specific disease?

In different cases of inflamed joints, inflammation is found to exist in all degrees, from the most acute, down to that termed chronic or scrofulous.

The flakes, moreover, of coagulable lymph met with in the pus are not peculiar to what is termed scrofulous inflammation; we meet with them in the pus in many other cases where suppuration is produced from chronic inflammation, more especially when the general health is much deranged, so that their formation cannot depend upon a peculiar constitutional scrofulous taint.

My plan of treating ulcerations of the neck produced by suppurating glandulæ concatenatæ, seems materially to corroborate my idea as to the non-specific nature

of these suppurations. I have been informed since I first commenced with this plan that it is not altogether new, but I wish to mention it to obtain its more universal adoption. After reducing cutaneous inflammation by the free employment of leeches, and the use of purgatives, so far as the patient's strength warrants, I have recourse to Baynton's method of curing ulcers of the legs:\* first, laying a layer of simple dressing over the ulcer so as to extend for a short distance over its circumference; upon that I apply soft compresses in the same manner, in order that every part of the circumference of the sore, as well as the surrounding skin for a limited extent, shall be equally pressed upon, and that the surface shall not be exposed to harsh pressure. The straps of adhesive plaster I then apply, not so as to strangle the patient, but to extend nearly half way round the neck, beginning with each at the nape, and bringing them forwards nearly as far as the pomum adami; at the same time the skin of the two sides of the sore is drawn into a state of approximation: the straps of plaster of the length specified will stick firmly if the composition is good, so as to draw upon the skin, and cannot inconveniently compress the larynx unless they are improperly brought over the pomum adami. If it is a large ulcer, the neck must be strapped from top to bottom, and the patient can comfortably and neatly wear his cravat over the straps with this injunction, that he do not inadvertently and suddenly twist his neck, so as to give himself pain, nor button his shirt collar too tight, as these are the causes most likely to excite irritation, so as to interfere with the healing. I need scarcely say, that as nothing is more likely to inflame superficial absorbent glands than cold and wet, the patient must preserve a free cutaneous action by being in winter clad with flannel. When all other remedies, internal and external, for the cure of these ulcerations have failed, with these simple dressings judiciously applied, the circumference of the ulcer after a short time becomes white and free from irritation, and rapidly grows over the ulcer, which has become as permanently cured as would any simple ulceration in any other part of the body.

---

\* I have found a composition of equal parts of emplastrum plumbi and roborans, with a moderate quantity of the hydrargyri rubri oxydum, considerably aids the effect of pressure upon these ulcers, probably owing to the plaster bestowing such a gentle stimulus to the wound as to excite the growth of healthy granulations.

## ON FIRING HORSES.

By CHARLES CLARK, V. S.

I AM unwilling to appear again here in the capacity of a critic, but cannot withhold from making a few remarks on the subject of firing horses for lameness, which not long since has been discussed in THE LANCET.

A veterinary surgeon, Mr. James Turner, asserts, page 843 of the last volume of THE LANCET, that the operation of firing has fallen into "disrepute," and after assuming this point, proceeds to advertise what he is pleased to call an "improved method," which is at present confined, we are led to understand, to himself and "his brother," and the success of which "depends solely on making each separate incision completely through the skin, cutis as well as cuticle, and boldly exposing the cellular tissue, forming the immediate covering of ligaments, tendons, periosteum, &c.;" and he tells us, that to cure a spavin in this style, great "dexterity, tact, talent, nerve, &c., are in requisition."

Mr. Turner has certainly calculated too much on the silence of his veterinary brethren in putting forth this information, and he has already been answered very ably and well by one of our best practitioners, Mr. Fenwick, excepting that this gentleman deals with his pretensions too tenderly. In the first place, I utterly deny that this operation is in "disrepute," either in town or country, except so far as College influence and College teaching extend, and have not only been very successful in effecting the desired object by it in my own practice, but, as Mr. Fenwick says, have seen it equally so in that of other veterinary surgeons; and in some instances, where I considered it a *sine qua non*, have not hesitated to guarantee the removal of the lameness, before the owner would submit his horse to the unavoidable blemish it occasions.

"Firing" is deprecated and disused by Messrs. Coleman and Sewell, but the only reason I have heard assigned for this, was from those who have witnessed the performance of the latter gentleman, viz., that he did not do it well; and as pupils are not taught to handle the irons at the College, it is very natural they should either discountenance the operation altogether, or otherwise do discredit to it. To such, Mr. Turner's *deep plan* may be a novelty; but I should think there are very few, even medical men of much experience in horse-flesh, who will not at once see through it as a mode of operating which has been in use for ages back among the most ignorant of

our farriers, who, arguing on their favourite apophthegm, that a "strong disease requires a violent remedy," have thought they added to the effect of their firing, in proportion to the depth they carried it through the skin. All enlightened practitioners, however, have agreed in approving the more moderate method, and Mr. Turner himself is obliged to admit, that this kind of firing is held indispensable by the majority of horse proprietors. But we are now to see "the phoenix rise from his dying ashes." If the measure proposed were merely useless, instead of being alike injurious, cruel, and *unscientific*, it might be passed over in silence. I say *unscientific*, because there is not in either of Mr. Turner's papers, any account of the principle upon which he fires thus deeply, nor a single passage which implies a knowledge of the action of the hot iron on the skin, much less that would convey such knowledge to others. Mr. Fenwick says, "I have not entered into the true *rationale* and effects of firing, which Mr. Turner does not appear to me fully to comprehend." I could wish he had done so, as it would have relieved me from a responsibility which I should not venture on, were it not necessary to show the fallacy of Mr. Turner's views. The following, therefore, must serve as an explanation.

The skin of the horse is much more sensitive and susceptible of irritation than the human skin, therefore blisters and external stimulants of various degrees, have always been among the most general and useful curative means in the power of the veterinarian. Of these means, the actual cautery is nothing more than the most potent and effectual.

About the legs, where this operation is generally performed, the skin may be from one-eighth to a quarter of an inch in thickness, according to the breed of the horse; and the method I have been taught and have practised is, to draw the red-hot firing-iron in regular lines, scarring through the cuticle and *upon* the cutis, but by all means avoiding to pass through it, or expose the cellular tissue beneath. On this account, the edge of the cautery should not be too sharp, or more than a red heat, lest it inadvertently, or by the animal's struggles, pass through the skin; nor should the operation be hurried, but each line passed carefully over, that the parts may be fairly cauterized, and not hastily cut through with a sharp hot instrument. The object in view is not to burn and destroy, but to *inflammate the cutaneous structure*; it is an operation performed *upon* the skin, and in order to produce the following effects:—The parts at first shrivel and contract under the application of the hot iron, but soon after become tumefied, nature setting up a counter action,

and a clear lymph exudes, sometimes in considerable quantities, from the cauterized channels, which continues more or less for about twenty-four hours. Dissection at this period shows the *cutis vera* and cellular membranes greatly thickened, and the capillary vessels injected with red blood. After this, the surface becomes dry and the limb stiff, the heat and tumefaction continue for many days, and the inflammation gradually subsides, leaving the parts still much thickened; and now begins that gradual absorption and tense state of the skin which are consequent on such a state of excitement, and are supposed to be the immediate means of removing that disease, whether consisting in relaxation of structure, osseous deposit, or otherwise, for which the operation was had recourse to. About two months' rest may be necessary, at the end of which time the parts resume their natural size.

Some have expressed the action of firing by saying, that it occasions the skin to form a tight bandage over the part which promotes absorption and cure, but we know not whether to ascribe its efficacy chiefly to this, or to the direct effect of counter irritation. It may be needful to dress the inflamed parts occasionally with emollient ointment, but I say nothing of the common practice of blistering immediately after the operation, because I think it often does harm, and is not involved in the question.

Now, according to the rationale of firing I have laid down, let us see what would take place, if through design or want of skill, or I will say ignorance, the cautery should be carried right through the skin to an uncertain depth in the cellular tissue; for, let me observe, that when once the dense *cutis* is divided, no hand can properly control a red-hot iron in the loose structure underneath it. The first effect will be a retraction of the divided edges, forming what Mr. Turner calls a *lesion* of the parts, and if all the straight and oblique lines are of this cruel depth, the limb would appear like nothing so much as a piece of roast pork in an eating-house window. Violent inflammation ensues, but very little discharge of lymph; and the first effort of nature towards a cure is to fill up these channels by fungous sproutings from the cellular tissue, of which all who have dealt with horses' legs, will understand the momentous mischief. At the same time, the skin, being detached and undermined, will probably ulcerate and slough away; and the leg heals, frightfully blemished, after double the usual time, and twice the amount of suffering to the poor animal. Horses have died in consequence of the excessive irritation. Every observer of horses must occasionally have noticed such specimens of firing; each line presents a long scarred seam as wide as a man's finger, perhaps; for

the edges of the *lesion*, or division, never properly unite, and the leg is swelled or considerably enlarged, because the skin, instead of retracting as in the former case, is actually destroyed and cut through, and in this state can afford no support to the contained parts. I will say nothing about the obvious danger of wounding the capsular ligaments, sheaths of tendons, nerves, &c., by this rude proceeding; but a man must have the *dexterity*, *tact*, and *talent*, of a Turner, to steer clear of them, and also an antiphlogistic power, that most of us are strangers to, and which I suppose must be a secret in the family, "never to permit or allow that sturdy opponent, inordinate inflammation, to gain a day's march upon him." It may be thought that I have exaggerated these disastrous consequences; but it is not only on my own authority that I assert that Mr. Turner has, and can have, no specific by which he can prevent them.

Mr. Fenwick says, that "inflammation and sloughing invariably follow, when, by accident, the iron passes through the skin and burns the cellular tissue; and every veterinarian knows it also; yet for this candid admission, Mr. Turner presumes to charge him with something like want of skill, or at least infers that he does not possess the "profound knowledge" of the Turner family. The best writers are of his opinion. Mr. Blaine remarks, page 674, "I must again caution the young practitioner to let no consideration induce him to fire through the cuticle; if the true skin be wounded, a very considerable inflammation and sloughing will follow." The reader may now judge of Mr. Turner's pretensions. We do not suppose him ignorant of the true rationale of the operation, but really his opinions would almost warrant such a conclusion. If he had advocated firing over a more extended surface, the cause would have borne dispute; but here he divides the *cutis* instead of cauterizing and inflaming it, destroying the very structure upon which the hot iron should act, and rendering it incapable of performing those beneficial offices of pressure and absorption that conduce to the removal of disease. He is angry at being treated as a quack, but his practice cannot be explained or defended by reference to any known laws of physiology respecting the skin; he never in the slightest manner adverts to or recognises them.

It is difficult otherwise to account for the benevolent proposition of exercising his deep method of firing on the limbs of mankind for "scrofulous inflammations of the synovial membranes of joints, &c.;" for under this impression he says, "If such cases have derived benefit from the days of Hippocrates down to Professor Rust's time, from only cauterizing or scaring the surface

of the skin, how much more may be expected by making numerous crucial incisions through the skin with the actual cautery." Here it is very evident that he does not understand the advantage of simply inflaming and corrugating the cutis; he would inflict a series of ghastly wounds, such as never entered into the contemplation of the scientific surgeons, whose moderate measures, he thinks, may sanction his gross proceedings. By going right "through the skin," much more might be expected, certainly, of inflammation and mischief, but not of good effect; as well might the trepanner argue, that if the removal of a portion of the cranium is beneficial, much more good might be expected from going deeper into the substance of the brain. None of the advocates of cauterization in human surgery have so forgotten the legitimate offices of the skin as to think of firing through it. The mosa, the ancient cautery, and the searing iron of the modern Indians, have all a superficial operation, and it has been reserved for Mr. Turner to propose a plan which sets physiology at defiance and astonishes the surgical world.

Presuming that Mr. Turner's two papers contain the gist of the promised volume, I have thought proper to discuss his opinions before they were more diffused, but refrain from many additional remarks which the subject suggests, lest the length of this matter should preclude its insertion.

Veterinary Infirmary, Stamford St.,  
Nov. 15th, 1839.

#### CASE OF UNUSUAL AFFECTION OF JOINTS IN SMALL-POX.

By MARTIN EVANS, M.D.

EARLY in last June a woman applied to me with a male child, about two years old, whom she said had been inoculated some ten or twelve days before by a quack doctor; at the same time stating a belief, that the matter inoculated must have been of a poisonous quality, as the child's health was rapidly declining. On examination, I found several parts of the body dotted with various pustules on the wane; the elbow-joints red, swelled, and extremely painful; inflammation had not proceeded to an equal degree in both, the left having already reached the stage of suppuration, indicated by evident fluctuation; the child had some lingering symptoms of febrile action, and was rather robust for his age. After some general questions I ordered alteratives; the left joint to be fomented, and the right to be treated with refrigerant lotions; leeches

were not employed, the mother being either unable or unwilling to procure them. On the following day the abscess in the left joint was so pointed, the superincumbent skin so stretched by accumulation of matter, and the entire collection not appearing to communicate so much with the interior of the joint as on the previous examination, that I was induced to make a puncture at the posterior part of the joint, a little above the ulceration, where the pointing directed; through this opening issued immediately about three or four ounces of perfectly-formed *laudable* pus, mixed with a little blood; a probe was then used, and a small portion of the end of the humerus was found rough and denuded.\* Common poultices were applied, on which a little pus appeared at each removal, and in a few days the wound healed kindly, notwithstanding the unfavourable features of the case.

I have been thus minute in describing the advance and decline of disease in this joint, as it faithfully represents the stages and treatment of similar inflammations, as they occurred in the right elbow, wrist, hip, ankle, and knee-joints, according as they progressed either successively or simultaneously. The corresponding joints, as those of the wrists, became affected simultaneously, and immediately subsequent to the elbow-joints; then the hip, knee, and ankles, followed without intermission; in all, inflammation ran its course rapidly, suppuration succeeding against every effort to prevent it. The wounds cicatrized well, and the patient was quite well at the end of July, nearly two months after I had first seen him.

My attention was called to this case in consequence of reading a report, in THE LANCET, No. 532, of similar cases brought forward by Mr. Stephens, at a meeting of the London Medical Society. This gentleman inclines to the opinion, that this remarkable affection of the joints arises from circulation of pus in the blood, and adduces in corroboration, "That in phlebitis, when adhesive inflammation took place, with a deposition of lymph sufficient to block up the vein, these effects (purulent depositions) did not ensue. This, to my view, only proves, that where the lymph was shed, there was inflammation bounded, consequently that its extent was not sufficient to light up general febrile action, which may be the

\* May we not suppose that the spongy parts of bones, from their greater degree of vascularity, being endowed with more life than the denser texture, resist death more effectually, consequently that injury or exposure of them will not always kill or create disease? certainly the proneness of parts to death is in an inverse ratio to their vascularity. This was illustrated to me a short time since in a child whose skull was extensively denuded by a fall, but from its greater vascularity at that age escaped without exfoliation.

cause of certain local disease, according to the parts predisposed to assume it. His other auxiliary proof is, "That there was a probable absorption of pus (in his case), as the pustules underwent an imperfect supuration." Even this appears to me rather hostile to his own theory, as the quantity of offending matter was less than usual, and we certainly cannot presuppose the formation of pus in the blood. In one way only can I understand how his latter argument could favour his theory; it is this: that according as pus was depositing in the pustules, the absorbents were *more than usually* active in taking it up. Is it probable that the febrile action, called forth during the existence of variola, excites disease in parts which are prone by nature to receive it, as we see in common continued fever? One point appears adverse to this conclusion, namely, that these affections of the joints appear only towards the subsidence, and not at the acme of the fever. Thus we arrive at a "conclusion in which nothing is concluded," and leave the field of conjecture *pendente lite*.

Teignmouth, Devonshire,  
November, 1830.

## DERBYSHIRE INFIRMARY.

### CASE OF "GOOSE EGG."—INFIRMARY INTELLIGENCE.

CASE.—Hannah Mansfield was sent into this Infirmary in a state of convalescence after typhus fever, to be nourished by the wholesome diet of the establishment. In Dr. Baker's case-book she is reported to have miscarried before her arrival at the Hospital, and to have had after-pains and moanings. Within the first ten days after the supposed miscarriage she had seventy leeches applied to the regions of the stomach and belly, and a blister to the abdomen, considerably larger than two pages of THE LANCET. This blister produced strangury, but did not slough; her phlegm was suspended, and barley-water was prescribed as an antidote; a pint of blood was also taken from the arm, but the pains still troubled both the doctor and his patient, and recourse was had to mercury; three grains of calomel and one grain of opium were administered every three hours. The evacuations produced, &c., did not subdue the supposed inflammation, though in addition to these depletions, nature was all along lending her powerful aid by a constant discharge of blood from the womb (flooding), so the doctor was puzzled, and rested from his labours; but whilst contemplating the consequences of this unquenchable inflammation, a most curious and astonishing sub-

stance came away from the woman, shaped like "a goose egg," and almost as large, composed of "skin," &c. This was promptly secured by the watchful house-apothecary, and nothing has been seen of it since. As on former occasions, however, expectation is alive, and it is hoped that Mr. Dix is engaged in hatching the egg.

After this abortion the uterine irritation ended, the patient and the doctor were relieved, and the pains and the flooding ceased. The woman, although of a good constitution, remained extremely weak, sweating profusely for a time. This, after such violent visitings and miscarriages, is not surprising, but fortune favours her, for she is recovering gradually, and drinks sherry every day.

We presume to contrast this case with another of Dr. Baker's, mentioned in THE LANCET of the 2nd of last month, when there was urgent vomiting, the stomach appeared to have been highly inflamed, the lungs congested with blood, and the patient died without any treatment calculated to subdue inflammation. An indolent uterine tumour absorbed all the doctor's attention, and this he tried to remove. We also recollect a case which was much talked of in the Infirmary, where the doctor used the stethoscope to a girl 17 or 18 years of age, and reported that he heard "mucous rattle." She had enlargement of the belly, and was treated with diuretics, expectorants, &c., till she was tired, and then refused physic. Her belly grew larger and larger, the dropsy did not dissipate, a parish officer was called in, he opened the doctor's eyes to the true nature of the case, removed his patient, and in due time the dropsy, to use a vulgar saying, fell into the girl's arms. The doctor seems a stranger to the peculiarities of the uterus, but he must have full credit for his unremitting attention to his infirmity patients. This ignorant woman, like Miss Louisa Smith of Newington Butts, says, "It is very kind" of him, and lauds the doctor for having cured her of a terrible inflammation of the belly. "If the patient lives, then has he one more to add to the surviving list; if he dies, then it may be justly said of the patient's disorder, that as it was not cured the disorder was incurable."—*Goldsmith*.

*Practical Queries*.—Did not the huge blister, by its strangury, &c., promote the abortion?—Would not mercurial action have the same tendency?—What was the bleeding likely to do?—Would not opium, and the "soothing system," have been more likely to have relieved the pains, and to have prevented the abortion?—Was not this a case of uterine irritation, and hæmorrhage without inflammation, occurring in a pregnant woman, debilitated by typhus fever,

the commencement of the flooding having been mistaken for a miscarriage, the miscarriage, in fact, not taking place till the patient had flooded for more than a week, and had been subjected to medical treatment well calculated to produce a miscarriage?

**Infirmiry Expenses.**—The Committee for inquiring into the causes of the 140*l.* increase in the expenditure for drugs, wine, &c., during the past year, will give their report to the Board in due time. The facts are these, as they appear from the Infirmiry account-books, and from the registered admissions of patients. Dr. F. Fox began his duties as attending physician to the Derbyshire General Infirmiry at the end of August, 1829. Dr. Forester having resigned, Dr. Fox came into his place, and therefore commenced with a full average of in and out patients. It must be particularly observed, that to the end of October (when Dr. Baker began to attend as physician), the drug expenses continued as usual, viz., for August, September, and October, the Derby drug bill did not amount to 30*l.* For the next quarter (Dr. Baker constituting the only alteration in the case, for the other medical officers say they had no new physic fit upon them), the drug bill was 50*l.*, Dr. Baker having but few in-patients (six or seven only); his out-patients about the same in number as Dr. Fox's. The second quarter Dr. Baker had more in-patients, say ten, and the Derby drug bill amounted to 59*l.*; and the third quarter, ending last June, Dr. Baker had 16 in-patients on an average, and the drug bill amounted to 88*l.* It is right to explain, that though a small portion of this account should have come into one of the other quarters, it still belongs to the year's expenditure.

The Weekly Board of Governors now took the affair up, having observed the growing evil for many months, and a report was laid before the Board, but the medical officers were not disposed to report "the whole truth," as it would have been personal to have done so. Even as it was, Mr. Wright was in jeopardy, being suspected by Dr. Baker. From this moment the Doctor checked his physic, his in-patients have been almost regularly decreasing, and the Derby drug bill for the last quarter has diminished to less than 26*l.* in amount. Dr. Fox's averages of in and out patients having continued, and continuing the same as they were before Dr. Baker commenced the intention of these investigations, has been fully answered, for a similar waste of 140*l.* per annum will not be permitted in future.

Nov. 18th, 1830.

## THE LANCET.

London, Saturday, Dec. 11, 1830.

HAVING, in our last Number, reduced the dignity of the present Royal College of Surgeons in London to the less ostentatious pretensions of the Company of "Shavers" which existed in 1460; having, in fact, shown the identity of the two corporations, as exhibited in their spirit of monopoly, and as legally stamped by the letters of their respective charters, we shall now pass on to the cloisters near Blackfriars Bridge, where we shall take a summary glance at the frail and aged SISTERHOOD.

The brief sketches of the state of medical law, which we have already presented to the profession, appear to have excited the shame and indignation of a vast number of medical practitioners. Enough, it seems, of the disgusting history has already been read, to convince every liberal-minded man that our medical corporations, from the first moment of their existence, have only acted as unyielding barriers to our scientific advancement. Great anxiety is consequently expressed on the subject of the plan for a NEW MEDICAL COLLEGE, and the hopes which had been previously entertained of the degree of its usefulness and importance, have been incalculably strengthened by the accession to power of many of those individuals who have long been denominated the "liberal" whigs. This anxiety, so natural to man, and so especially natural to the victims of persecution, shall not, however, betray us into a premature disclosure of the details of the scheme for the formation of a new College. The enemies of reform are ever loud in their denunciations against "dangerous innovations," and a proposal to repeal an "Act of Parliament," or to abrogate a "Royal Charter," is as horrifying to the ears of a monopoliser, as the appalling agitations of an earthquake. Whilst, therefore, we take this opportunity of cau-

B B

tioning our brethren against being deluded by expectations founded upon an "official" change of men and names, we would urge them to investigate, with their utmost attention, the present and past state of medical government. Then, and not till then, will they be secure against delusive promises; then will they treat with becoming contempt any hypocritical proposal, however high the quarter whence it may emanate, for a patch-work reformation. *Reformation*, did we say? Medicine, like the Royal Society, demands a *new* constitution. No "*reforming*" of the old statutes can give the least satisfaction or security; they are all intrinsically, radically, bad—alike disgraceful in spirit and in letter. The medical body, it may be truly said, at this moment presents a correct epitome of what is passing in the political world. It is, in fact, an "*imperium in imperio*." There is the tyrannical ruling oligarchy, the sycophantic, craving, expectant, conceited, aristocracy, and the persevering and meritorious labouring classes, who enjoy no privilege from their nominal superiors, save that of relentless persecution. A complete uprooting, then, of the medico-legal statutes, is what is demanded by every sensible man; but before entering into a detail of the description of substitute that will be required, it is only prudent that we should thoroughly comprehend our present position. Evils are never so successfully opposed as when their extent and bearings are well understood. There is no safety when fighting against enemies who are concealed in ambush. Proceed we, then, to exhibit *en deshabille*, the unsightly corporation, which has so long been permitted by the "Vice Society," to disfigure the Hall of the Company of Retail Drug-dealers.

The Apothecaries boast a higher origin than the Company of Surgeons, having originally been associated with the grocers, from whom, in fact, they sprang. The an-

dient apothecaries traded indiscriminately in all those articles which are sold by the distinct trades of grocers and chemists of the present day. In those times the travelling quack carried on a most flourishing business, and was the only exclusive dealer in medicines. The cures performed by this description of persons have been much spoken of by ancient writers, but of their professional murders nothing whatever has been stated, neither are there any accounts of the patients having been "rubbed out" of existence, as by one infamous quack of our own times. The ancient apothecary, besides carrying on the business of a grocer, acted upon all occasions as the willing tool or servant of the physician, whom he regarded as the great possessor of all learning and knowledge. The knock of the gold-headed cane was magical to the ear of the apothecary, and the shake of the Doctor's wig would half-frighten him out of existence. The friendly intercourse which existed between the doctor and the apothecary is thus spoken of by CHAUCER in his character of the "Physician:"—

"Ful redy hadde he his apothecaries,  
To send him drugges, and his letturaries,  
For oche of hem made other for to winne;  
Hir friendship n'as not newe to beginne."

Whatever, therefore, may be said, in the way of reproach, of the percentage system, now supported and carried on by the doctors and dispensing chemists, the custom may certainly boast of antiquity for both its authority and justification. From preparing the prescriptions of physicians, and from their long experience of the action of various medicines when prescribed by others, the apothecaries at last began to take upon themselves the cure of the sick, and thus intruded upon the province of the "Doctors." The trade of grocer not exactly agreeing with the notions of dignity entertained by these subordinate doctors, they sought to be divorced from the retailers of sugar and butter, and at last so far succeeded as to obtain a charter of incorporation in the

thirteenth year of the reign of JAMES the First. This charter decreed that the apothecaries should constitute a distinct Company, and be entirely free from the regulations and jurisdiction of the Company of Grocers; and the King, after lamenting that the grocer-apothecaries had sunk into disrepute, and were despised, decreed that the new Company should constitute a corporation by the name of the "Master, Wardens, and Society of the Art and Mystery of Pharmacopolites of the City of London." After going through the usual clauses, which are to be found in the charters of that period, respecting "lands," "liberties," "common seal," &c., the Company was authorised to make ordinances for the regulation and government of all persons practising as apothecaries in, and within seven miles of, the city of London, but no regulations, relating to medicines, or their compounds, could be made by them without previous consultation with the president, and the four censors, of the College of Physicians. The principle for regulating the elections was the same as is to be found in all the ancient charters, namely, the *self-perpetuating*. Respecting the business of the apothecary, it decreed, that no persons in London, except those of the Apothecaries' Company, should keep any apothecary's shop, make, compound, administer, sell, send out, advertise, or offer for sale, any medicines, distilled waters, compounded chemical oils, decoctions, syrups, electuaries, pills, powders, lozenges, plasters, or otherwise practise the faculty of an apothecary within seven miles of London, under the penalty of five pounds a month, leviable by distress. Further, it was ordained that no person should practise as an apothecary unless he had served an apprenticeship of seven years with some freeman of the Company, and had afterwards presented himself for approval before the master and wardens, assisted by the president of the College of Physicians, or by

physicians appointed by him to inquire as to his "knowledge, and choice, of simples, and as to the preparation, dispensing, application, mixture, and composition, of medicines."

The Company was likewise empowered to examine the shops of all persons carrying on the business of apothecary in London, or within seven miles, whether freemen or not. They were also authorised to examine all persons whom they might find practising as apothecaries, and to prohibit them from practising, should they be found deficient in a knowledge of pharmacy; and they were further empowered to destroy, before the doors of the offenders, all such medicines as they might deem adulterated, or unfit for use, and inflict penalties besides.

This charter secured to the College of Physicians the whole of their privileges, and "all surgeons experienced and approved were to exercise their art and faculty, and use and enjoy their proper practice in the composition and application of external medicines, so that they did not vend medicines, or expose them for sale, according to the common practice of apothecaries."

In an Act passed in the reign of WILLIAM III., and which was made perpetual in the 9th GEORGE I., apothecaries in actual practice were "freed from the several offices of constable, scavenger, overseer of the poor, and all other pariah, ward, and leet offices, and from being put into, or serving upon, any juries or inquests." Apothecaries not being freemen of the Company, in practice beyond seven miles of London, were allowed similar privileges, provided they had served an apprenticeship of seven years.

Such were the provisions of the Charters of the Apothecaries' Company down to 1815, when was passed the statute entitled, "An Act for better regulating the Practice of Apothecaries throughout England and Wales;" but a more appropriate designation would have been,—“An Act for enabling the Apothecaries' Company of London

to harass the minds, and extort money from the pockets of, the whole body of English Medical Students, to confuse the Judges of the Land, and to take from the Members of the Royal College of Surgeons, nine-tenths of their rights and privileges." How the Company must have chuckled at its success in obtaining this Act! It has thrown thousands upon thousands into their coffers; but a more useless and worthless piece of legislation never issued from the houses of Parliament. This we shall prove by contrasting its powers with those of the Charter from which we have just quoted. The Company, we are well aware, pretend that the act was, in a manner, forced upon them by the proceedings adopted at the meetings of general practitioners held in the years 1812-13-14. These meetings certainly produced a great sensation amongst the profession throughout the whole country, but they were sadly misconducted, and, taking advantage of the slight knowledge possessed by the most active of the agitators, the College of Physicians and the Company of the Apothecaries, who had acted as bottle-holders until the combatants were exhausted, altogether ousted the wranglers from the field. The conquerors were then enabled to make their own terms, and the two houses of Parliament, without scruple or hesitation, applauded and confirmed their manœuvres for monopoly. If the Apothecaries' Company had been moved by the slightest feeling of regard for the welfare of the profession or the community, such an Act as that passed in 1815 would have proved altogether nugatory. The Charter of JAMES I. gave them ample power to protect the public from incompetent pharmacopolites; but it did not confer upon them the privilege to extract, at their discretion, money from the pockets of the medical students. This was the omission, which, in the eyes of the keen-sighted Company, rendered an Act of Parliament indispensably necessary, and bottomed as was that act in the most inveterate avarice,

it has proved, as might have been expected, a measure of monstrous iniquity. If it be contended that the decision of the House of Lords in 1703, in the cause—"Coll. Phys. v. Rose," led to a material alteration in the practice of apothecaries, we deny that that decision in any way affected the legal powers of the Company, as defined by their then-existing charter; it altered not their legal position, and we repeat that the Act of 1815 was only rendered necessary, because the charter of JAMES the First did not confer upon them the privilege of extracting the *fee* shillings for a "license" to practise as an apothecary.

---

A CORRESPONDENT, who signs himself "FAIRPLAY," has addressed to us the following note:—

"Sir,—As you have often criticised the practice of our hospital surgeons with severity, let me ask how a case of "Tumour in the neck," treated by Mr. LAWRENCE, as detailed in the last number of your Journal, can be justified? And whether his last operation for cataract does not deserve censure?"

FAIR PLAY.

"Dec. 7th, 1830."

We certainly cannot approve of the practice of the surgeon in either of these cases; neither do we approve of an operation, the particulars of which will be found at page 380 of our present Number.

---

WE should be cruelly and criminally deficient in the discharge of our duty towards the afflicted portion of the public who seek relief in our hospitals, if we were to omit directing the attention of the governors of these institutions, to the circumstances under which the patients are frequently discharged. It often happens, that poor creatures who have been for weeks bedridden, and subjected to long courses of mercury, are sent out of the hospitals at a few hours' notice, without having a friend to apply to for relief, or a bed whereon to rest their aching bones. It was only about

twelve days since, that four patients called at the private residence of the Editor, to complain of the sudden manner in which they had been dismissed from St. Bartholomew's Hospital; and we have little difficulty in saying, that two of them were in a most unfit state to be discharged, and quite certain are we, that no private patient who could have paid a *fee*, would have been turned into the street under similar circumstances. One of these poor creatures was from Yorkshire, and had not a single friend or relative in London; yet he was so much disabled, that it was only with the greatest difficulty he could walk. On the Sunday he had been directed by the house-surgeon, Mr. ———, to keep in bed; on the Monday he was deemed by the visiting surgeon a fit subject for the streets.

And these are our charitable hospitals!

---

"*REX V. LONG.*"

(*Note from Mr. HENSON the Solicitor.*)

---

"9, Bouverie-st., Fleet-st.,  
Dec. 7, 1830.

"SIR,—Understanding that you wish me to send you the particulars of the costs incurred in this prosecution, and the monies allowed by the county, I beg to forward you the following memorandum:—

"Entire amount of costs in the prosecution of LONG .....	£	s.	d.
	132	1	3
"By cash allowed by the County of Middlesex for the witness- es, and received of the treasurer on the 8th of November	42	11	6
<hr/>			
"Leaving the amount of costs incurred by you as the prosecutor .....	89	9	9

"Of which 89*l.* 9*s.* 9*d.*, fifty-five pounds were received by me before the petition was presented to the treasury, leaving a balance still due from you of 34*l.* 9*s.* 9*d.*, in addition to which will be the costs of the petition to the Lords Commissioners of the Treasury, which will amount to 5*l.* or 6*l.* more.

"I have not as yet been enabled to procure an answer from the Solicitors of the Treasury, to whom the petition is submitted, nor shall I for some months to come, because the petition is referred from the Solicitors to the Attorney and Solicitor General, who will report thereon to the Lords of the Treasury.

"I remain, Sir, yours truly,

"W. S. HENSON.

"T. Wakley, Esq. Bedford Square."

The Lords of the Treasury now in office, are not the gentlemen to whom LONG's fine of 250*l.* was paid; if they were, we should be inclined to say a few severe words to them upon delaying for some months the consideration of such a petition as the one we presented. The difficulty, inconvenience, and expense, incurred in prosecuting criminals in this country, have long effectually obstructed the full administration of justice. From what we know of Earl GREY, the first Lord of the Treasury, and Sir THOMAS DENMAN and Sir WILLIAM HORNE, the Attorney and Solicitor-General, we are inclined to believe that Mr. HENSON will receive an earlier reply to his application than the hitherto tardy proceedings of the Treasury have led him to anticipate.

---

ATTORNEY-CORONERS are so extremely anxious for medical men, the only competent persons to preside over inquests, that they are availing themselves of every opportunity to show that their ignorance of law is equal to their ignorance of medicine.

The attorney-coroner of the City held an inquest on the body of the boy who was operated upon by Mr. EARLE (whose case is recorded at page 380), and the coroner and jury, we should think, were not a little surprised when they heard, that a "mallet" had been extracted from the child's *ear*. Of what use are such inquests?

## WESTMINSTER MEDICAL SOCIETY.

November 13, 1830.\*

Mr. CHINNOCK in the Chair.

## GONORRHOEA, AND THE IDENTITY OF ONE FORM OF THAT DISEASE WITH SYPHILIS.

Mr. BACOT. I rise to acquit myself of the promise made to the Society last Saturday, to bring under consideration the subject of gonorrhœa, and the question of its identity with syphilis. It is not my intention to occupy the time of the Society with a detail of the symptoms and method of treating gonorrhœa; it is a disease so universally known, that to dilate upon so trite a topic would be more than useless, though I believe there are few practical men who will not readily admit that gonorrhœa, however common it may be, occasionally presents difficulties in the cure, and anomalies in the progress of the symptoms, sufficiently vexatious to the most experienced; however, putting this view of the subject aside, at least for the present, I will proceed at once to draw your attention to the identity of one form of this disease with syphilis. In doing so I must not only entreat your attention, but your favourable consideration, for I feel that I am struggling against the general opinion of most modern practitioners, and that I am especially opposed to some of the most distinguished men of the present day. If this were a mere hypothetical question, it would be undeserving of our consideration, but as it involves, in the course of the discussion, circumstances that occasionally throw a shade of suspicion upon female chastity, and destroy the peace of the domestic circle, besides that it leads to some practical conclusions, it has strong claims upon our attention. The term gonorrhœa, in its usual acceptation, implies, as we all know, a purulent discharge from the organs of generation, attended with pain and scalding in passing the urine; to these symptoms I restrict the definition of the disease, because the superadded symptoms, which are almost endless, are not *essential* to the disease, neither do I include in my definition the usual term "the produce of impure connexion," because that is not an essential circumstance to the production of discharge from the sexual organs, and the impure origin of which can only be made out by the confession of the patient, or from other evidence than the mere symptoms; thus in the female it is impossible always to distinguish between a venereal discharge

and mere leucorrhœa; in many female infants also, the symptoms above mentioned, discharge from, and inflammation of, the genitals, with pain in making water, not unfrequently accompany certain forms of struma; in the male the presence of stricture will often produce the symptoms of gonorrhœa, passing a bougie will do the same, and no doubt a man may produce a discharge from the urethra, arising from inflammation of the mucous membrane of the urethra and simulating gonorrhœa, whenever he chooses to apply any irritating substance within that passage. None of these facts can, I apprehend, be doubted; and if not, then we have abundant sources of what may be, and has been, repeatedly called gonorrhœa, without having recourse to sexual intercourse; for if we have all the above-named symptoms, in conjunction with redness and tumefaction of the orifice of the urethra in the male, and turgescence and redness of the mucous lining of the labia and vagina in the female, I apprehend no man will rely upon the mere appearance of the discharge, to settle the point as to whether the complaint is the produce of connexion or not, much less whether it be the result of impure connexion. Now it is well known that what we call gonorrhœa has been recognised from very early times; it is described by all the older writers; and how should it be otherwise? So long as mucous linings are liable to inflammation, so long, under various circumstances of disease, either constitutional or local, must gonorrhœa have existed. I need not quote authorities to prove so notorious a fact, they are to be found in every book, and the regulations of the Bishop of Winchester's stews in particular will not only show the frequency of the complaint, but what of course does not admit of doubt, the facility with which the discharge, however arising, can be communicated by intercourse between the sexes: this then puts us in possession of the fact, that not only did purulent discharges from the organs of generation prevail long before the disease called syphilis was known, but that it so existed both as a constitutional disease, as well as a consequence of promiscuous intercourse between the sexes. But now comes the question, Is gonorrhœa a form of syphilis? or, in plainer language, Does the poison of syphilis ever attack the mucous lining of the organs of generation, producing the symptoms of gonorrhœa without a breach of surface, and known by its causing the usual secondary symptoms of the lues venerea? I assume that it occasionally does, and shall proceed to state shortly the grounds upon which I have formed this opinion; but I have some difficulty in doing this, because the subject is so extensive, and the authorities so nume-

\* Want of space prevented the insertion of this Report in its proper place.

rons, that I can scarcely do more than glance at the labour that has been bestowed upon the inquiry, in which so much ingenuity has been displayed, and so many mistakes committed. It is well known that the identity of the two diseases has been warmly espoused by Hunter, Foote, Swediaur, Sawrey, Lagness, Carmichael, and several others, and that it has been especially opposed by B. Bell, and other equally respectable authorities, as well as by the tacit consent, if I may so say, of the bulk of the profession. As usual, both parties appeal to practical facts and direct experiments, to prove their respective positions. Now I will at once declare that, in my mind, none of the recorded experiments are at all satisfactory; those of Hunter fail, from the mode in which they were conducted; the appearances produced by inoculation were interfered with by art, and the belief that the cure of a disease by mercury proved its nature to be syphilitic, renders all his labours nugatory; but then the same must be said of the trials made by B. Bell, because they only go to prove that, in a very limited number of instances, the insertion of gonorrhoeal matter into the skin of the penis, or *vice versa*, was unattended by the expected proofs of the mutual conversion of the two diseases; but when the numerous instances of discharge from the urethra are considered, it would not change my opinion in any degree to find a thousand instances of failure in the production of a syphilitic sore by the insertion of gonorrhoeal matter; whilst on the other hand, if one successful experiment can be quoted of this kind, the matter is settled; and this is asserted to have been said to have been done by Dr. Harrison. To constitute a fair set of experiments on this subject, it would be necessary to recollect that the inoculation of the matter, from a syphilitic sore, requires some discrimination, for all sores on the genitals are not syphilitic, and that its insertion into the urethra is not necessarily attended by a similar ulceration, all that can be reasonably expected is, that an inflammation of the mucous membrane, and in consequence a discharge of pus, should take place, the specific nature of which can only be proved by its after-consequences. Secondly, it is necessary, in performing such experiments, that every curative means whatever should be avoided, and that the processes should be left entirely to nature. Thirdly, that the inoculation should be performed from one individual to another, and not on the same person; and fourthly, the *experimentum crucis* should be demanded, namely, to produce a syphilitic sore from the inoculation of gonorrhoeal matter. So much for the experimental part of the inquiry. With regard to other evidence, we have the positive as-

sertion of Swediaur, that he has met with secondary symptoms arising from what he calls bleenorragia only; cases are also related by Vegarou and Lagness, tending to the same point; the former records a fact of six Frenchmen having had connexion with the same woman, one after another; three of these men contracted chancre, two gonorrhoea, and one escaped with a bubo only. A case of the same kind is related by Mr. Hennea, but it would be uncandid not to state that all these relations are imperfect, inasmuch as the exact condition of the female is not given with the necessary clearness to make the case conclusive. There is also an indirect testimony in Mr. Evans's pamphlet favourable to this view of the subject. That gentleman tells us that at an inspection of the public women which he attended at Valenciennes, out of one hundred only two were affected with ulcerations, and at Little nearly the same proportions existed, and yet the men continued to present the same proportion of ulcers on the genitals as usual. I proceed in the next place to observe that shortly after the introduction of syphilis among the nations of the Continent, surgeons almost universally took up the doctrine of the identity of the two diseases, and all our own practical writers not only assumed the matter without hesitation, but proceeded to the cure upon this presumption, and some of them go so far as to say that gonorrhoea is always a proof of first infection. One of the ablest of these writers (Mr. Wiseman) affirms that he has met with various individuals infected by the same woman having chancres, some of whom contracted gonorrhoea, and others sores only, and it is by no means unusual to observe the same thing now, but there is nothing conclusive in this, because it is not always, nor perhaps often, possible to affirm that a female with gonorrhoea has not deeply seated in the vagina an ulcer also; neither do I wish to draw any decisive inference from the belief expressed by the writers of the sixteenth and seventeenth centuries in favour of the identity of the two diseases, because it is quite clear that in the vast majority of instances, gonorrhoea, though a venereal complaint, that is to say a complaint produced by means of sexual intercourse, is not syphilitic, that is, does not lead to secondary affection. But I can conceive that the surgeons of those days, though aware that gonorrhoea had existed long before the invasion of syphilis, still were induced to consider it to be part and parcel of that disease, in consequence of their observing that secondary symptoms did really flow from it, and thus from too great a fondness for generalizing facts, they took it for granted that all discharges from the urethra had a syphilitic origin; and in my opinion there are facts enough to warrant any belief that

there exists a *symphilitic* species of gonorrhœa, from which may proceed pains, ulcers in the throat, eruptions on the skin, and other symptoms recognised as the true consequences of syphilis. Of such consequences I shall relate three examples, and then conclude, by a summary of my views stripped of all unnecessary *verbiage*, after making a few remarks upon the practical inference derivable from these views. About ten years ago I was called to attend a young gentleman labouring under gonorrhœa, the symptoms of which were very severe; this young man was of very irritable habit, and had contracted the disease in the usual way; there is nothing peculiarly deserving of attention in this case excepting the great severity of the inflammatory stage of the disease, which was attended by such an enormous swelling of the prepuce, that the relations of the gentleman became alarmed, and as he was highly connected, it was thought right to join the late Mr. Pearson in consultation. It is needless to repeat the mode of treatment adopted, and I only mention Mr. Pearson's name in order to record the expression that he made use of to me when he quitted the patient, whom he saw only once. He said, "If I were in your place, when the disease is nearly subdued I would exhibit mercury, for I have seen many evil consequences follow such cases of gonorrhœa." I did not, however, follow this advice, and my patient, after remaining quite well for two months, became affected with ulcerations of the tonsils and palate, and finally recovered with some degree of deformity, exfoliation of part of the palatal bones having taken place. Now, I can confidently assert that this gentleman had gonorrhœa only; I inspected him repeatedly and minutely, and I can truly assert, that not a particle of cuticle was destroyed or abraded on any part of the genital organs. My second example is that of a medical pupil, who, about two months after the cure of a severe gonorrhœa, applied to me on account of superficial ulcerations of the tonsils, pains in the limbs, and a profuse eruption of lichen simplex over the whole body. His remark upon coming to me was, "Sir, I always denied the possibility of secondary symptoms arising from gonorrhœa, but now I am unfortunately convinced of its truth." The alterative administration of mercury was recommended, and the patient speedily got well. The third case which I shall trouble you with is that of a female, a patient at the St. George's and St. James's Dispensary, who laboured for many weeks under a profuse purulent discharge from the vagina, with great turgescence and redness of the whole external organs, and ardor urinæ, but who nevertheless wished to pass off this disease as mere leucorrhœa. Whilst under treatment, she was

seized with a smart attack of fever, preceded by pains in the limbs, and in forty-eight hours was covered with one of the most profuse and distinct crops of copper-coloured spots I ever witnessed; she was then really, in plain language, ashamed to show her face, and I saw no more of her. I have stated but three cases, and those very shortly, in order to spare the valuable time of the Society; but I trust that enough has been said to afford matter for reflection, and, at least, to excite the attention of those who hear me. Perhaps it may be asked, What is the advantage of this discussion, and to what course of practice does it lead? My answer to this is,—that the advantages of this discussion are two-fold;—in the first place, if it be true that numerous discharges from the genital organs of either sex may arise without sexual connexion, important practical conclusions may be the consequence, saving, perhaps, many females especially, from misery and disgrace; it may teach us, in our medical capacity, some degree of caution in pronouncing upon the venereal nature of such discharge, and thereby save us also from much difficulty, and sometimes from censure. It is not above three months ago that I witnessed a severe discharge, with intense ardor urinæ, and considerable local irritation of the external organs, in a young female between thirteen and fourteen years of age, who had never yet menstruated, but in whom the signs of puberty were beginning to develop themselves, and yet certainly, both from inspection of the parts and other circumstances, it was impossible that sexual intercourse could have taken place. Now had this female been but a few months older, or so situated as to have been exposed to suspicion, the medical man's opinion might have been decisive as to the future prospects of this poor girl. Now with regard to discharges avowedly the result of impure connexion, and where it may be suspected that after-consequences may ensue, I do not propose materially to vary the treatment, because I am induced to believe that one species of that disease is syphilitic; but I do think it is of importance to remember, that symptoms may arise, demanding our serious attention, and to the nature of which we must not wilfully shut our eyes; that in very severe cases of gonorrhœa, it may be advisable to let our patient know the risks that impend over him, and occasionally, perhaps, to terminate the cure by an alterative dose of mercury, a medicine which I consider absolutely mischievous and improper to be given during the earlier stages of the disease. I have purposely omitted any mention of those symptoms which immediately and avowedly flow from gonorrhœa, and gonorrhœa only, such as

various species of ophthalmia, rheumatic pains, especially those of the feet, all of which are sometimes very troublesome sequelæ of the disease, but which, nevertheless, have nothing to do with the question at issue; and I will now conclude by referring to a few sentences in a work which I lately published, wherein this question is treated of at some length. It cannot have escaped your penetration, Sir, that the time devoted to our discussions has compelled me to waive many arguments, and to pass unnoticed many interesting points connected with this inquiry; but I hope enough has been said to excite the interest, and to call forth the opinions, of many gentlemen around me, fully competent to put me right if I am in error, since truth alone is, and ever ought to be, the object of our search.

Dr. SIGMOND disputed the correctness of Mr. BACOT's chronology of the disease. He could never perceive the slightest similarity between the two diseases, but considered them perfectly distinct; the only circumstance he could allow at all favourable to the doctrine of identity, was the necessity of administering small doses of calomel after gonorrhœa.

THE PRESIDENT complimented the author of the paper on the clear and comprehensive manner in which he had treated the subject; he expressed his concurrence in his doctrines, and stated his surprise, that in the list of authorities corroborating his views, the late work by Mr. Travers had not been referred to; to this he called the attention of the Society.

Mr. BACOT said, he had not been able to comprehend Mr. Travers' work, otherwise he should have adverted to it.

Mr. EVANS related a very clear and interesting case that had fallen under his own observation, bearing particularly on the question, where gonorrhœa was followed by secondary symptoms to a violent degree, and required the exhibition of mercury, sarsaparilla, &c., for its cure. He had, previously to this case, been decidedly opposed to Mr. BACOT's doctrines. A similar case was related by a gentleman whose name we could not learn.

Dr. GRANVILLE, during his travels on the Continent, had had many opportunities of investigating the subject; his attention was particularly called to it in some parts of the Peninsula; he expressed himself favourable to Mr. BACOT's views.

Dr. BARRY opposed the notion of the identity of the two diseases. Dr. Copland followed him by supporting the identity. The discussion was very animated, and the majority of the members were inclined to support Mr. BACOT's opinions.

## SPONTANEOUS EVOLUTION.

To the Editor of THE LANCET.

SIR,—I have read with much interest in the last number of your valuable LANCET, the details of two cases of "spontaneous evolution," by Mr. Cooper, of Brentford; and certainly, as far as the subject of evolution is concerned, they are interestingly illustrative of that mysterious power, whereby nature produces so admirable an adaptation of means to the end. An observation of nature and her mode of action has been, since the earliest ages of medicine, the directing principle in the building-up of theories, and the application of remedial agents; but there are few instances, indeed none, where her power is so strikingly displayed, as in the subject before us. So far Mr. Cooper deserves the thanks of the profession, but I regret that we cannot bestow our meed of praise on his line of practice in his first case. He says, "Introductory pains commenced on Saturday; the pains continued at intervals until Tuesday evening, when I was sent for. On examination, I found that the membranes were not broken. On Wednesday I was again sent for, and now I discovered the arm presenting, and so firmly wedged in, that the child could not be turned."

Now, Sir, Mr. Cooper on his first examination tells us, that the membranes were not broken. What condition the os uteri was in, or what was the presenting part, he does not say; but if he could find that the "membranes were not broken," he certainly could ascertain the condition of the os uteri and the presenting part; now Mr. Cooper did or did not ascertain the presentation on Tuesday; if he did, I consider that a degree of culpability is to be attached to him in consigning to her fate a poor creature, when he could, before the evacuation of the waters and the impaction of the child in the pelvis, turn with ease to himself and safety to the mother, and if he did not, he cannot claim the tact of a tyro, much less that of a practitioner of 14 years' standing. I shall not insult the understanding of your readers by quoting proof of the propriety, nay, necessity of this proceeding, it being insisted on in the lectures and works on midwifery. Well then, on Wednesday Mr. Cooper finds himself in a dilemma, he cannot turn in consequence of the opposing power of the uterus; having no data to proceed upon, and finding himself in the by-paths of uncertainty, he betakes himself to "*physiological reflection*," and the effect of his physiological ratiocination is to subdue the strong action of the uterus. Surely the profession will hail with gratitude so happy an *idea*.

Mr. Cooper then proceeds to overcome this obstacle, but lo and behold, after he has accomplished his end, i. e. the relaxation of the uterus, he throws himself into the arms of Morpheus, and desires to be called when uterine action comes on again, the very thing on which he had wasted so many physiological ideas; however, he left a good midwife (nature), and by a most fortunate occurrence, evolution took place, and saved the patient's life and the doctor's reputation. I need not ask, Would any man be mad enough, in cases of that kind, to trust to spontaneous evolution?

Allow me to apologise for this communication, and to assure Mr. Cooper that I have not been actuated by any personal feelings, and do really tender him my thanks for laying the cases before the profession.

I am, Sir, yours,

OBSTETRICUS.

London, Nov. 29, 1830.

#### SUPPRESSION OF QUACKERY.

Dr. H. C. FIELD, of Baggot Street, Dublin, writes to us as follows:—"As I think the opinion of so numerous a body as the medical practitioners, on this side of the Channel, should give some additional preponderance to a cause in which they are, with English practitioners, equally interested, I have for some time anxiously hoped (but in vain) that some one, on the part of the former, more capable, would express his great sense of obligation for your exertions, and of the justice of a general demand for a protecting law against all kinds of medical empiricism. Permit me to say that we have felt here most indignantly on the subject of the empiric Long. The ebullition of angry feeling is now subsiding into contempt for him, with astonishment and disapprobation, however, at the encouragement given to quackery by the trifling punishment inflicted." The doctor continues his strictures at some length, and calls upon the press to lessen public credulity,—unhappily a demand much more easily made than accomplished,—and concludes by imploring the legislature to take immediate steps to guard the community against the plundering and murderous proceedings of quacks.

#### OBSTETRIC SOCIETY.

A correspondent (*Argus*), in making some observations on the proceedings of the "Obstetric Society," observes that "its exertions might have been rendered far more efficient if it had been thrown open to the profession, instead of being confined to a few who may be said to have a direct interest in the question. There is not a man practising midwifery in the united kingdom

who would not have come forward and most readily have joined in a petition to the legislature. One word to the secretaries of the Obstetric Society. As in the "full plénitude" of their candour they published the proceedings of the Society, why did they not also publish the correspondence which took place between the Colleges of Physicians and Surgeons and themselves, through the ex-Secretary of State for the Home Department? From undoubted authority I am informed that the epistles from the learned and most liberal bodies, would make the hair on the head of an intelligent person stand on end.

#### ASSOCIATION OF MEDICAL PRACTITIONERS AT NEWCASTLE.

THE members of the medical profession at Newcastle-upon-Tyne, at a meeting held a short time since at the Assembly Rooms, Mr. Baird in the chair, have unanimously agreed to a series of resolutions expressive of their opinions on the dissatisfactory and degrading custom of charging for medicines as a mode of remuneration for the exercise of professional skill, and that the nature and extent of services actually rendered, are the only just and rational basis for obtaining compensation. In accordance with these views a table of fees and charges "specifying the several services which practitioner may be called on to render, with a reasonable but adequate sum affixed to each, adapted to several ranks and circumstances of the community," was adopted, each practitioner affixing his name to it as a pledge of his using it in all practicable cases.

A resolution was also entered into, that those practitioners who acceded to these regulations should form themselves into a Society, to be called "The Newcastle and Gateshead Association of General Practitioners in Medicine and Surgery," which Society is to hold meetings once or twice a year for the consideration of subjects connected with their joint interests and well-being, and for the promotion of social and friendly feelings amongst the members.

We are sorry that the secretary, Mr. T. M. Greenhow, did not forward to us the table of charges, as it might be acceptable as a guide in other cases. Mr. Greenhow observes in a note accompanying the resolutions,—“In consequence of the address of the Metropolitan Society, a correspondence has been commenced with that body, but it does not appear that they expect to be able soon to accomplish any-thing connected with a better principle of remuneration, though it is part of their ultimate object. At any rate it is obvious that a general movement in the profession would hasten and facilitate incalculably, such an intention on their part.”

## CURE OF ENLARGED SPLEEN BY IODINE AND THE HYDRIOATE OF POTASH.

Dr. W. M. West, of Newbury, has forwarded to us the particulars of a case of great enlargement and induration of the spleen, with alarming symptoms. The disease had existed for nine or ten years, and it was successfully treated in the following manner:—

“ I began with small doses of iodine, one grain every four hours, which I continued for nearly a month, without producing the slightest effect; I then added half a grain more, to be repeated every five hours, and to rub the hydriodate of potash on the part affected night and morning. In a fortnight I saw her again, and perceived a considerable change for the better. I then increased the iodine to two grains every six hours, prolonging the intervening periods, to prevent its exciting pain or uneasiness of the stomach; after taking this for a week, she complained of slight pains like the colic, with pains of the head, as described by Professor Brera and many others. During the omission of the iodine, I ordered the hydriodate to be persevered in. In a week, all those feelings that had appeared to be aggravated by the former treatment, were subdued; I then ordered a quarter of a grain of opium to be added to each dose of the iodine, and this was persevered in until a perfect cure was effected, which took place, as nearly as I can recollect, in about three months.”

## ASSOCIATION OF MEDICAL PRACTITIONERS IN GLASGOW.

The want of a medical institution accessible to every respectable member of the profession, had been long felt in this city. Although there is a very extensive and valuable library already in existence in Glasgow, it belongs exclusively to the members of the Faculty of Physicians and Surgeons, who form but a small proportion of the practitioners of Glasgow and its neighbourhood, and whose demands from new entrants in the shape of entry money are so exorbitant, as to prevent many who would otherwise have joined them from entering their body. For the purpose of establishing an institution on liberal principles, and calculated to be generally useful, a considerable number of medical practitioners and medical officers of the army and navy resolved, in the year 1824, after various meetings, to form themselves into a medical, literary, and benevolent society, under the designation of “ The Glasgow Faculty of Medicine,” declaring all regularly-licensed physicians and surgeons eligible for becoming members. Two-thirds of the annual subscriptions, which are only 25s., with one guinea of

entry money, go to the library, and the remaining third to form an ordinary fund for defraying the necessary expenses of management, and for granting relief to decayed members or their families. In connexion, a widow's fund has been established, by which a regular member may insure to his widow (by annual payments) any annual sum, from 10*l.* to 30*l.* according to approved tables adopted by the faculty, and which have stood the test of experience else where in similar associations. The faculty, in their hall, vaccinate gratuitously, and distribute lymph to all applicants weekly. There is also a medical literary society, without additional expense, the entering which is optional with the members. The library has rapidly increased, and now contains the greater proportion of the standard medical works, with other publications, inclusive of all the approved periodicals. This association has now placed the means within the reach of all our professional brethren, of keeping pace with the march of improvement in the healing art.

As there are many young practitioners in the vicinity of Glasgow who may have heard of this association only through some prejudiced medium, and who are therefore ignorant of its real objects, I have been instructed by the Faculty of Medicine to transmit to the editor of *THE LANCET* the above sketch, in the hope that with his usual urbanity and zeal for the interests of the general practitioner, a corner may be spared in an early number for its insertion.

WM. E. C. CLARK, Sec.

Faculty of Medicine Hall,  
St. Andrew's St., St. Andrew's Sq., Glasgow,  
Nov. 18th, 1830.

## SURGICAL LECTURES IN THE DUBLIN COLLEGE.

A CORRESPONDENT (Y. Z.), who dates his letter from Dublin, complains of the mode in which the lectures on surgery are delivered at the Dublin College by Mr. Wilmot. “ Four of these lectures (he observes) are delivered weekly; two of them by Mr. Colles, and two by Mr. Wilmot. This latter gentleman delivers his lectures in such a low voice, that they are absolutely inaudible to nearly one half of the class. Thus those of the pupils who cannot get to the front seats, are completely debarred from obtaining the knowledge for which they have paid. Besides, when Mr. Wilmot speaks, his manner is confused, and he evidently labours under great paucity of words; defects than which I know none more disagreeable, and few more prejudicial to the interests of students. A *copia verborum* is essential to the successful communication of knowledge to others, and where wanting, no

extent of acquirements will make up for the deficiency. I have only to hope that some improvement will speedily be effected in these lectures; for I certainly know that the gentlemen whose first season is the present, have been sadly disappointed.

#### CURE OF HYDROCEPHALUS.

MR. R. S. RICHARDSON of Holborn, states that "a case of hydrocephalus in an advanced stage" was treated successfully by him in the following manner:—"The patient, a boy *ætat.* three years, had been attacked eight days previously to his being called in, at which time he was in a state of insensibility, and apparently dying. Mr. Richardson says, "I found the little patient insensible, sawing the air and picking at the bed-clothes with one hand, whilst the opposite side appeared motionless and paralytic. The respiration was difficult, and there were repeated attacks of convulsions. The eyelids half concealed the pupils, which were dilated; bowels inactive; alvine dejections dark-coloured and fetid; pulse quick and weak; head of a hydrocephalic form. As the bowels appeared to have been neglected (the evacuations being scanty, dark-coloured, and offensive), I prescribed a brisk purgative, consisting of five grains of the powder of scammony and calomel, and two grains of jalap, immediately. This I directed to be followed up every four hours with a mixture of infusion of senna and tartrate of potash. I also directed the warm-bath to be employed, four leeches to be applied to the temples, and sinapisms to the feet. Drastic purgatives were exhibited daily, the warm-bath was employed every evening, and the feet were kept in a constant state of vesication by means of sinapisms. By perseverance the bowels were completely cleared, and a state of hypercatharsis (as some would term it) was produced. The little patient gradually recovered the use of his faculties, but appeared restless, peevish, and irritable. I now suspended the use of purgatives, and ventured to exhibit one minim of tincture of henbane four times a-day, which tranquillized the child, and appeared to accelerate the cure. The tincture of henbane was succeeded by the administration of infusion of senna and tartrate of potash, so as to relieve the bowels twice or thrice daily, and I am now happy to say that the child has perfectly recovered. This case serves to show that we never ought to despair, even under circumstances apparently the most hopeless and unpromising."

#### EFFICACIOUS ADMINISTRATION OF CROTON OIL.

MR. A. SCOTT, of Sydenham, has communicated to us the particulars of a case in

which the croton oil was used with the most decidedly good effects on a patient who was reduced to the lowest state of emaciation and debility. The illness, which had arisen without any obvious cause, had been progressive for many months. The patient was a child about ten years of age; exhaustion and loss of appetite were the only prominent symptoms, but these were so extreme, that the powers of speech and motion could hardly be exerted. Change of air, various aperient medicines, calomel, leeches to the head, tonics, &c., were resorted to, not only without good effect, but with decided aggravation of the symptoms. "Under these circumstances," Mr. Scott says, "I proposed the administration of the croton oil, which, after again trying some other purgatives without effect, was given in the manner following:—Two drops were divided into three pills, and one directed every hour. The first and third were retained on the stomach, but the second was rejected. Three copious fetid motions were the consequence; and on seeing her the following day, I could not help thinking she looked better, though I feared to express a hope, so completely were the minds of her parents made up as to the event. The stomach was more tranquillized, and in a day or two she was able to retain pills of the *ext. colocyn. c.*, which happily kept up the action of the bowels, the evacuations became more natural, and in a few days she took a little nourishment. Her recovery has been rapid and progressive."

#### ST. BARTHOLOMEW'S HOSPITAL.

##### EXTRAORDINARY OPERATION—DEATH.

THOMAS BRADY, *ætat.* 7, was admitted into Keaton's Ward on Monday, the 22d of November, under the care of Mr. Viucent.

On Friday, the 19th, whilst at play with some other children, he put the round head of a nail into his left ear. He was unable to get it out again, and his father took him to a surgeon for the purpose of having it extracted. The gentleman to whom he was taken, told the father that he could distinctly see the head of the nail, and that if the boy would allow him, he could easily extract it. The boy objected strongly to this measure, and it was necessary to have him held by four men, but their efforts were not sufficient to retain his head at rest, and consequently no attempt at extraction was made. When he was brought here he objected so strongly to the examination of his ear, that it was necessary to have him held by several assistants. This being done,

Mr. Vincent proceeded to introduce a probe, which, when it had been passed about an inch, could be distinctly heard to strike some metallic substance, which appeared to be firmly impacted in the tympanum. As it could not be moved with the probe, several pairs of forceps were successively introduced, and with each of them the piece of nail was taken hold of, but could not be extracted. Mr. Vincent used as much force as he thought prudent, and from the boy's efforts to get away his head, he must have lacerated the membrane lining the meatus, which was followed by tolerably copious hæmorrhage. Mr. Vincent then desired him to be put to bed, to have his ear syringed with warm water, and afterwards a bread-and-water poultice to be applied, and in the evening six leeches, to the ear.

25. He has suffered no pain in his ear or head; the several functions are regularly performed, and he appears perfectly well. There is a free discharge of pus from the ear.

Dec. 2. The discharge from the ear stopped this morning; he has headach.

3. Much better. Mr. Vincent ordered the leeches to be repeated.

4. He has very little pain in the head, and appears free from the symptoms which attacked him on the 2d. Mr. Vincent to-day requested Mr. Earle to endeavour to extract the nail, which he immediately proceeded to do. He began by introducing into the meatus a director, which he used with so much force, that he bent it; dressing forceps were then employed, with which he laid hold of the nail, and pulled so forcibly, that he bent them also. Another pair was tried, which unhappily met with a similar fate. A pair of forceps, with hooks at the extremities, was then used, but they were soon bent straight; several attempts were made with different instruments, but the nail could not be moved, though Mr. Earle exerted great strength on the occasion. Mr. Earle then requested Mr. Vincent to make an incision of about an inch long parallel to the posterior part of the ear, and to divide the meatus auditorius. This Mr. Vincent immediately did, and Mr. Earle again proceeded to search for the nail. Forceps of different kinds were repeatedly introduced, but they either bent, or slipped their hold every time. An elevator was had recourse to, but it was equally unsuccessful. A pair of tooth-forceps was next employed, and after laying hold of the nail (as Mr. Earle said), and pulling very forcibly, he at length succeeded in extracting three pieces of metal, which appeared to be portions of the head of a nail. Encouraged by this success, he introduced the forceps again, and extracted the *mallet-bone*; they were again repeatedly introduced, and

though Mr. Earle enclosed the head of the nail between the extremities of the forceps (as he said), nothing but *portions of bone* were extracted. Mr. Earle now called for a pair of wire-nippers, for the purpose of cutting the nail in two; but some gentleman observed that they would be too large to be introduced into the tympanum. He said that it was evident that the nail was bent, and was "lying in the posterior part of the tympanum," and talked of trephining the mastoid cells, but soon abandoned the idea. On looking through the incision which had been made, bone could be seen at the bottom of a deep cavity. Mr. Earle said it was the external boundary of the tympanum, and thought that the nail was lying against it; but he again, in a few minutes, changed his opinion, and said he did not know where it was. The patient had now been on the table about *an hour*, and it was found that he was nearly exhausted; his pulse could scarcely be felt, and his skin was bedewed with cold perspiration. Some wine was offered him, which he refused; his pupils were dilated, and it was considered necessary to desist from any further attempts; to have him put to bed, and to have a bread-and-water poultice applied to the ear, and to give ten drops of liq. ant. tart. every four hours. Mr. Earle then stated that "he had used more force than was warrantable." He consoled himself, however, that there was now a large opening, through which pus might escape if it should form, but yet he feared that part of the petrous portion of the temporal bone would exfoliate, and that inflammation would come on in the brain, and occasion abscess and death. He stated that he had seen three or four similar cases which had terminated in this manner!

5. Has not spoken since Mr. Earle's operation; he has been insensible ever since; groans a good deal, as if in pain; pupils very much dilated, and the approach of a lighted candle occasions very little alteration in their size. There is no discharge from the ear; pulse very rapid, and scarcely perceptible; bowels open once during the night. His mouth cannot be opened sufficiently wide to allow his tongue to be seen. He has not slept since yesterday. Mr. Vincent saw him to-day, and ordered a blister to be applied to the back of the neck, and to take ten grains hyd. c. creta every eight hours.

6. Eleven A.M. Is perfectly insensible; has not spoken since the 4th. He continued to groan loudly till ten o'clock last night, but since then he has been perfectly quiet. Countenance is now cadaverous, and lips are exsanguine; eye-lids half closed; right pupil very much dilated, left contracted; a lighted candle brought close to them occasions no change; pulse cannot be felt in

either wrist; the heart beats very feebly and rapidly; respiration hurried and frequent; there is also gargouillement; bowels not open since our visit yesterday. Saliva is seen flowing from the corner of the mouth; skin bedewed with cold clammy perspiration. He has taken his medicine regularly; blister has not risen; he appears to be in *articulo mortis*. We returned at one o'clock to see him, and were told that he had been dead about an hour.

*Post-mortem Examination four hours after death.*

**Head.** About four ounces of serum were found between the dura mater and arachnoid membrane. There was softening of the entire extent of the base, and of the anterior part of the hemispheres. The vessels on the surface were very much distended, but the substance of the brain was very pale. The ventricles were examined, but nothing particular was discovered in them.

**Ear.** The temporal bone being removed from the skull and the soft parts stripped off, the cavity of the tympanum was immediately brought into view, without anything else being done. Not a vestige of the bony portion of the meatus auditorius externus remained, the whole having been removed in the operation, and the floor of the tympanum was also wanting. The remaining portion of the tympanum was covered with pus, which being washed off, the surface of the bone beneath appeared highly inflamed. The nail not being in the tympanum, sections were made through the cochlea, vestibule, semicircular canals, and mastoid cells,—but there was no nail to be found!

STRANGULATED HERNIA.

*Condemnation of a Practitioner in words, by a Surgeon, who on Saturday last condemned himself in DEEDS.\**

A man, apparently about 25 years of age, was admitted into Darker's Ward with a strangulated congenital hernia, on the right side, on the 7th of December, at two p.m., under the care of Mr. Earle. He stated that he has had a rupture many years, but that he had always been able to return it himself until last Saturday, the 4th instant: it then became strangulated, and the symptoms have since then been progressive. Mr. Earle considered that the case would admit of no delay, and proceeded to perform the operation immediately, which he did in the usual manner. On cutting into the sac, some dark-

coloured fluid escaped; it also contained some omentum and intestine; the omentum appeared mortified, the intestine was dark-coloured and exhibited numerous gangrenous spots; a few adhesions existed between the omentum and gut, but they were recent and easily separated; the mortified omentum was removed, and an incision of about two inches in length was made into the intestine, but no hæmorrhage followed it. The other proceedings exhibited nothing particular.

After the patient had been removed to his bed, Mr. Earle addressed the class. He began by *deprecating*, in the strongest terms, the *malpractice* of the medical man to whose care the patient had been entrusted, and said that he felt assured that if the operation had been performed at a proper time, the man's life would have been saved. He stated that he feared the man had now but a very slight chance of recovering, but in the event of his doing so, he would have an artificial anus; he said that all his operations for strangulated hernia had been successful when they had been done in time. In the present instance, the case was of that kind which he had taken the liberty of calling scroto-vaginal, in contra-distinction to the vaginal hernia that occurs in the female. The stricture existed at the superior part of the tunica vaginalis, at that part which, in the natural state, contracts to inclose the spermatic chord.

After making these remarks, Mr. Earle visited the patient, and found it necessary to give him brandy, which he rejected the moment he had swallowed it.

Ordered to take a saline draught, with a drachm of sulphate of magnesia, every hour, and an enema containing an ounce of castor oil, directly.

The enema was administered, but returned immediately; he has taken the medicine every hour, but vomited immediately after each dose. Towards the evening his abdomen became much more painful, and the slightest pressure on it caused great pain; he had constant vomiting; pulse feeble and slow, and there had been no evacuation from the bowels; he appeared to be in a state from which he could not recover.

We will give the result of this case.

**HIGH TEMPERATURE OF THE FLUIDS.**—In a case of dropsy related by Mr. Hunter, the fluid drawn from the abdomen was 104 deg. In a case of ovarian dropsy which I lately attended with Dr. Gibson, the thin fluid drawn from the general cavity of the abdomen, raised the thermometer to 102 deg., though the thick fluid from the cyst was only 100 deg.—*J. Burn's Surgery, vol. I.*

\* Mr. Earle should remember the "note and the beam."

## EXTIRPATION OF THE FIBULA.

At a late sitting of the Société des Sciences Naturelles et Médicales, at Brussels, the following case was reported by Dr. Sentin.

M. Hallemans, *ætat.* 39, of a robust constitution, was admitted at the Hôpital St. Pierre, under the following circumstances:—About six months ago he had, without any obvious cause, been affected with violent shooting pain in the right leg, on the lower portion of which an ulcer subsequently formed, and gradually enlarged, being accompanied with intense pain and considerable swelling of the whole leg. On his admission the ulcer was about one inch and a quarter in diameter, its margin was inflamed and very painful, and at the lower part of it there was a sinus which was found to terminate at the fibula. The general health of the patient had within late begun to decline, he lost his appetite, complained of fever, and restlessness at night, &c.; so that Dr. Sentin having convinced himself that the bone was affected, decided upon removing the diseased part of it: an incision of three inches in length being made at the outer side of the leg, the bone was laid bare, but proved to be diseased to a much greater extent upwards than had been anticipated; the incision was accordingly enlarged, and the bone being laid bare in its whole length, was found to be almost thoroughly diseased; a small portion of it only was healthy, from which the diseased part was removed by means of a trephine; the adhesions of the soft parts to the bone were then divided, and the inferior portion of the fibula detached from the astragalus by a curved saw. A large number of vessels were tied, amongst which was the posterior tibial artery. The peroneal nerve was likewise divided; at the lower part of the tibia the bone was also, though but slightly, diseased, it was, however, considered prudent to have the actual cautery applied to it. The edges of the wound were brought together, except at the lower part, where a tent was placed between them in order to promote suppuration. On the third day after the operation the dressings were removed with the exception of the uniting bandage; suppuration had begun at the inferior part of the wound. On the fourth day the edges of the wound were much inflamed, swollen, and painful; an erysipelatous redness began to extend over the whole limb, the patient complained much of headach, giddiness, &c., there was much fever, and considerable irritation of the digestive and respiratory organs. The dressings were entirely removed, and an emollient poultice put on in their stead, and the patient was largely bled. Under this treatment the fever and local irritation subsided; the wound suppurated rather profusely, but

had on the seventh day a good appearance. The favourable progress of the case was, however, somewhat interrupted by a severe attack of pneumonia, which was happily subdued by repeated venesection. On the 14th day the wound looked well; some aponeurosis and tendinous parts came away, and the tendon of the peroneus longus being almost entirely destroyed, was cut through at the place where it passes behind the ankle; the pus was healthy. The wound was dressed with dry lint and cerate. From the 20th to the 30th day the state of the patient greatly improved, the wound became much smaller, and the irritation of the lungs also completely disappeared, so as to admit the use of tonics and nourishing food. On the 30th a small piece of the tibia exfoliated at the place where the cautery had been applied. Two months after the operation the patient was quite well, cicatrization was complete, and his general health had also much improved; the movements of the limb were at first rather limited, but gradually became as free as before, so that after some months' exercise he was able to return to his former employment.—*Gaz. Med. de Paris.*

## HEADACH CAUSED BY THE PRESENCE OF A SCOLOPENDRA IN THE FRONTAL SINUS.

We extract the following case from the report of the "Société des Sciences Médicales, du Département de la Moselle."

A farmer's wife, twenty-eight years of age, residing in the neighbourhood of Metz, had for a long time been affected with an unpleasant itching sensation in the nose with coryza, to which symptoms in the year 1827, violent headach acceded, so that she was at length obliged to apply for medical aid. The headach was irregularly intermittent, and generally began at the root of the nose and the middle of the forehead, or at the right frontal region, extending thence first to the right side, and then over the whole head. The attack was accompanied by a great discharge of tears, and sometimes even nausea and vomiting; the features were forcibly distorted, the jaws firmly closed, and the eyes and ears so very sensible, that she could not bear the least light or any noise. At other times she became delirious, pressed the head between her hands, and ran about in a state of distraction. The pain was, according to her statement, like the strokes of a hammer, or as if something was perforating the skull, and the fits generally returned about twelve times in twenty-four hours; sometimes the headach continued uninterruptedly for several days. The coryza existed during the whole period, and the discharge was occasionally very fetid and

mixed with blood. Some medicines were employed, but no regular plan of treatment was followed, and it was not before a twelve-month's suffering that this singular affection terminated, after the expulsion of a worm from the nose, which moved with rapidity, and when placed in water, remained alive for several days; it was afterwards killed by being put in alcohol, and sent to M. Maréchal, who reported the case to the Society. He found the animal to be more than two inches in length, and one line in breadth; it had two antennæ, was of yellowish colour, flat, and consisted of sixty-four rings, on each of which were two legs. M. Maréchal subsequently transmitted the insect to MM. Hollandre and Roussel, who ascertained that it was a scolopendra electrica.

#### EFFECTS OF THE BITE OF A VIPER.

In the *Comptes des Travaux Méd. du Dep. de la Moselle*, M. Beaumont, of Briery, reported the case of a young, robust man, who, in the summer of 1827, was bitten by a viper under the following singular circumstances:—

The boy had been out on a hill in the neighbourhood of Homecourt, and saw two snakes, which he killed, by dividing them into several pieces with a hatchet. A few moments afterwards he came back the same way, and finding one of the heads lying on the ground, he picked it up, and was going to throw it away, when he suddenly felt a bite in the index of the right hand; he tried to shake the head off, and at last, with some effort, succeeded in detaching it from the finger, on which he saw two stings, at the distance of about half an inch from one another. He immediately returned home, but had hardly gone a hundred paces when he felt a violent pain in the throat, giddiness, and extreme lassitude, so that he could hardly walk; fortunately there was a house at about a hundred paces from the spot where he had been bitten, and after extreme efforts succeeded in reaching it; on his arrival he felt so faint that he was obliged to lie down; he felt sick; had a slight fit of syncope, and vomited a large quantity of bile; at the same time his tongue began to swell, so that he could not articulate. About an hour after the accident a silk thread had been placed around the finger, but was afterwards taken off by a surgeon, who cauterised the wound; the hand, arm, and even the whole of the right side of the trunk, began to swell under violent pain, so that the patient repeatedly fainted away. The application of a hundred leeches to the hand and arm, as well as the use of embrocations and poultices, were without any effect, and the

pain and swelling still continued, and increased to such an alarming extent, that a physician, who meanwhile had been sent for, advised the sulphate of quinine in large doses, which having been administered, the patient felt immediately relieved, and under the continued use of quinine perfectly recovered on the eighth day, with the exception of stiffness in the arm, which, however, also gradually subsided.

#### CONGENITAL WANT OF THE IRIS.

Dr. HENTZSCHEL, of Chemnitz in Saxony, gives an account of three sisters with the above malformation. The parents are still alive and in good health; the eyes of the mother are well formed; in those of the father the upper portion of the iris is entirely wanting. He is presbyopic, and cannot bear any strong light. He is frequently subject to ophthalmia, and within the last four years his sight has become much impaired. In the eldest daughter, who is 28 years of age, the iris is completely wanting, she suffers greatly from photophobia, and is almost constantly affected with ophthalmia, in consequence of which a staphyloma has formed in the left eye. On the cornea of the right there are a few nebulæ, the lens is of a greyish colour, and sight is very much impaired.

In the second daughter, 21 years of age, nearly the same symptoms are observable, and there is no iris in either eye; she is affected with photophobia, and very liable to ophthalmia; the sclerotic is very thin, so much so, as to permit of the choroid shining through at several points; in the left eye vision is very deficient; in the centre of the right cornea there is a greyish spot, which, however, not only does not impede vision, but seems even to facilitate it, by lessening the intensity of light.

In the youngest girl, who is 13 years of age, sight is also impaired, though to a less degree than in the two elder sisters.

There are two more children in the same family, a girl and a boy, the eyes of whom are perfectly well-formed.—*Ammon. Zeitschr. f. Ophthalmologie.*

#### TO CORRESPONDENTS.

A CORRECTED list of those Fellows of the Royal Society, who openly and honourably supported Mr. Herschel, shall appear next week.

(Other Correspondents must stand over.)

JOHN LONG.—This wretch has not yet (Thursday, December 9th) surrendered himself to take his trial at the Old Bailey.

## MEDICAL JURISPRUDENCE.

### PRACTICAL COMMENTARIES ON DR. CHRISTISON'S PROCESSES FOR DETECTING POISONS.

#### LEAD AND ITS PREPARATIONS.

DR. CHRISTISON subdivides the chemical part of his excellent article on lead into two sections, one referring to its detection after it has been administered in large quantities; the second to its relations to medical police, comprehending the mode in which it is affected by water—its use in several arts—the adulteration of various articles of food to which it is applied. To the first section we must limit ourselves exclusively, recommending to our readers the attentive perusal of the second, which we have no hesitation in asserting to be the most brilliant and masterly application of chemistry to medico-legal inquiries which has ever been made in this or any other country. The patience, the profound knowledge, and the manipulatory skill, displayed by Dr. Christison on this subject, would entitle him, if he had never written another sentence, to be ranked amongst the most distinguished chemists of the age.

The author, following his accustomed arrangement, first describes the metal and such of its compounds as come within the province of judicial research. Of these he enumerates litharge, or the semi-vitrified protoxide, minium, or the red oxide, and the acetate, or sugar, of lead. All these, he correctly states, agree in the property of being blackened by sulphuretted hydrogen gas. The acetate is soluble in water, the litharge, and carbonate, in nitric acid, and

No. 381.

the red oxide, but partially soluble in that menstruum. Carbonate of lead also, when heated to redness, assumes as it cools a yellow colour, the carbonic acid being expelled, and the yellow protoxide remaining behind. The solutions of lead are extremely liable to decomposition by animal or vegetable matters, many vegetable infusions, and almost all animal solutions, precipitating the oxide of lead in combination with organic matter.

We pass over the enumeration of the tests which the author recommends for detecting lead in pure solution, reserving our observations on them till we notice his mode of proceeding with complicated mixtures.

*"Process for detecting Lead in mixed Fluids."*—A solution, if necessary, is, in the first place, to be made in water. Professor Orfila in the early editions of his Toxicology advises that the soluble and insoluble parts be separated by filtration,—that the fluid be subjected to a stream of sulphuretted hydrogen, and the sulphuret reduced with black flux,—and that, if no lead be procured by that process, the insoluble matter left on the filter be incinerated, and reduced. In the last edition of his work the plan recommended consists in simply evaporating the whole fluid to dryness and incinerating it in a crucible; when a button of metallic lead is procured."—p. 408.

Nothing can be more practically absurd than Orfila's directions in this instance; we quote them principally to justify the scepticism in great authorities, which we expressed in the first of these papers. To look for metallic globules in such a mass of carbonized materials as would result from the incineration of a complex animal mixture, would be almost as hopeless in practice, as the attainment of the object which, in nursery metaphor, is called "seeking a needle in a bundle of straw."

"The process which has appeared to me the most convenient is a modification of the

CC

former one. In the first place, a little nitric acid should be added to the suspected matter before filtration; for nitric acid I find redissolves any insoluble compound formed by the salts of lead with albumen and other animal principles, as well as some of those formed with vegetable principles; and consequently renders it more probable that the poison will be detected in the first part of the analysis, if present at all.\* This being done, sulphuretted hydrogen gas is to be transmitted through the fluid part of the mixture; and if a dark-coloured precipitate is formed, the whole is to be boiled and filtered to collect the precipitate."—pp. 408, 409.

Several other black precipitates are thrown down, however, from metallic solutions by this re-agent, viz., from the soluble salts of mercury, silver, copper, bismuth, &c. A mode of discrimination, therefore, becomes essentially necessary, and the author proceeds in the following manner:—

"In order to ascertain that the precipitate positively contains lead, I should advise a different process from that recommended by Orfila, which I have found to give, on a small scale, metallic particles of too small a size and indistinct an appearance. Those who are accustomed to use the blowpipe may put the sulphuret into a little hole in a bit of charcoal, and reduce it by the fine point of a blowpipe-flame, when a single globule is procured, which is easily distinguished by its lustre and softness. A much better process, for those who are not accustomed to use the blowpipe, and perhaps a better test of the existence of lead in all circumstances, is to heat the sulphuret to redness in a tube, and to treat it with strong nitric acid, without heat or with the aid of a gentle heat only. The lead is thus dissolved without the sulphur being acted on. The solution is then diluted with water, filtered, evaporated to dryness, and gently heated to expel the excess of nitric acid. If the residue be dissolved in water, it will present the usual characters of a lead solution when subjected to the proper liquid tests. Of these the hydriodate of potass is to be preferred when the quantity is too small for trying more of them. But for this purpose great care must be taken to expel all excess of nitric acid, because an excess will strike a yellow colour with the test, though lead be not present.

"If the preceding process should not detect lead in the filtered part of the mixed fluid, then the insoluble matter left on the

filter is to be incinerated as Orfila suggests. This branch, however, will be very rarely required, if lead be present, because the precaution of adding nitric acid previous to filtration, dissolves the lead from most of its compounds which are insoluble in water. The process of incineration in medico-legal analysis generally should be avoided if possible, as it is not easily managed by unpractised persons."—pp. 409, 410.

It appears above, that Dr. Christison does not consider the reduction of the metal essential, and that he considers the effect of certain reagents as sufficiently characteristic; these he has described at p. 382. The best, he states, are the chromate of potass, hydriodate of soda or potass, and metallic zinc; the first two cause lively yellow precipitates, the third produces the deposition of the metallic lead in an arborescent crystallization. To the two former of these tests, individually considered some objections apply, none of which have escaped the author's notice, but to none does he pay the special attention which the strictness of these investigations demands. Thus, the sulphate of copper is precipitated black by sulphuretted hydrogen; this black precipitate is dissolved by nitric acid, and when evaporated to dryness and again redissolved, will strike a yellow colour with hydriodate of potassa, unless all excess of acid be expelled, which, in unpractised hands, will not usually happen, the evaporation being usually concluded when brought to dryness; whereas, from the tendency of nitric acid to form bi or super-salts, a bi-nitrate of copper is usually produced, the excess of acid in which acts on the hydriodate in the described manner. We may add also, that from the scandalous adulterations of the hydriodate of potash of commerce, the evidence of the whole experiment may be destroyed at this stage of the inquiry, carbonates, chlorides, &c. being precipitated, and obscuring the colour of the hydriodic acid. In minute quantities, finally, the action of metallic zinc will not assist us, for it certainly is not entitled to the epithet "delicate" applied to it by the author.

It is thus evident that in small quantity, and under the management of an inexperienced person, the several tests may have been applied to a copper solution, and positive testimony given to the detection of lead. We are, therefore, inclined to prefer the re-

\* The precipitate formed by acetate of lead with albumen is dissolved by nitric acid. From that formed with milk the acid removes the oxide of lead entirely, leaving the casein.

duction process as performed on charcoal with the blowpipe flame, an operation which is extremely easy, and affords at once the most beautiful and satisfactory evidence which can be obtained. Minute instructions will not, however, be misplaced, and we would recommend the operator to practise the experiment on sulphuret of lead, before he proceeds to the examination of the suspected substance.

A small hollow should be scraped in a piece of dense fine charcoal, and in this the sulphuret should be placed, moistened with a drop of distilled water, in order to make it adhere to the support; it should then be touched with the *interior* or blue flame of the blowpipe, when the reduction almost instantly takes place. The little globule of metal should then be removed and examined, for we have now to distinguish it from silver, which, take it in the pure state, is a white, shining, and soft metal; the globule should, therefore, be flattened by gentle pressure, replaced on the charcoal, and touched with the *furthest* point of the flame, when it quickly disappears, and on withdrawing the charcoal, two beautiful concentric circles of red and yellow remain, being the yellow and red oxide of lead. Nothing can be so conclusive as this experiment, and its success is perfectly certain.

When a soluble salt of lead is taken to an excessive dose, the phosphate of soda, or sulphate of soda or magnesia, should be administered as soon as possible, and vomiting speedily excited; an insoluble sulphate or phosphate is thus produced, and an effectual antidote supplied. A point now remains for consideration, which Dr. Christison has entirely omitted, viz. the means of detecting lead in the condition of the extremely insoluble phosphate or sulphate contained in the vomited matters; for this purpose the matters should be agitated with a considerable quantity of water; this mixed with solid matter, the phosphate or sulphate from its weight quickly subsides, and should be collected, washed, and heated to redness with charcoal in a glass-tube; phosphuret, or sulphuret, of lead is thus generated, either of which may be reduced by the blowpipe in the manner above directed; the reduction should be accomplished in the interior flame, when, if the salt be the phosphate, which the analyst should always inquire,

the process presents a modification thus described by Griffin, in his excellent *Manual on the Use of the Blowpipe*, p. 177, and for the accuracy of which description we can vouch from repeated trials.

“ Before the blowpipe alone on charcoal, in the *exterior* flame, it melts, and on cooling forms a dark-coloured polyhedral crystal, the faces of which present concentric polygons. In the interior flame it exhales the vapour of lead; the flame assumes a bluish colour, and the globule on cooling forms crystals, with broad facets inclining to pearly whiteness. At the moment it crystallizes, a gleam of ignition may be seen in the globule. If the crystallized mass be pulverized and heated with borax, there results in the first place a milk-white opaque enamel; upon the continuance of the heat this effervesces, and at length becomes perfectly transparent, the lower part of it being studded with metallic lead.”

Another and still easier mode is, to suspend the phosphate or sulphate in water, transmit sulphuretted hydrogen, wash and reduce by the blowpipe-flame. In both cases the concentric circles of red and yellow oxide remain on the charcoal when the flame is removed.

The foregoing extracts and remarks are amply sufficient for the guidance of the examiner of matters of food, drink, &c., suspected to be adulterated with lead, with the exception of cheese, which has been, and is, occasionally, coloured with red lead. In this case the cheese should be chopped into fragments and suspended in water, when, if blackened by sulphuretted hydrogen, the indication may be considered decisive without further trouble.

---

*Elements of Chemistry, including the Recent Discoveries and Doctrines of that Science.* By EDWARD TURNER, M.D., Prof. of Chem. in Univ. of London. Third edit., 8vo. pp. 900. London, Taylor, 1831.

We feel much pleasure in recording our decided approbation of this excellent work, and in affording testimony to the great ability and industry manifested in the improvements to be found in this edition. The book as it now stands, is not only highly creditable to the author, but is calculated to confer additional reputation on the institution to which he is attached.

In the present volume, Dr. Turner does not depart in the slightest degree from the excellent arrangement which he has hitherto observed, one in which he differs materially from many of his contemporaries, but which we confidently believe is better suited than any other to the construction of an *elementary* treatise, that is, to a work not so much intended for the reference of scientific chemists, as for the guidance and instruction of the utter novice in the art. The simple substances by this method follow each other in strict succession, uninterrupted by a too theoretical adherence to their supposed ultimate habits or electric relations. The mind of the pupil is thus gradually, and imperceptibly, conducted to the knowledge of facts, and afterwards taught to apply them with more certain, and satisfactory, precision. The several individual substances Dr. Turner treats with great judgment, omitting, in most instances, all the unnecessary accumulation of irrelevant and useless circumstances which crowd the works of the continental chemists, and which threaten, shortly, to render the details of chemistry almost as incomprehensible as infinity itself.

The principal improvement in this edition is, the introduction of Berzelius's doctrines on "haloid" and "sulpho" salts. Some change may also be noticed in the statement of the theory of galvanism. The experienced reader will, moreover, observe many minor additions and alterations, corresponding to the progress of this zealously-cultivated science. The greater number of these have been drawn from that admirable periodical the *Annales de Chimie*, and many of them have already been transferred to our pages. For the benefit of our junior readers, we subjoin in the foot-note the names of the new substances treated of in this edition, to which our space does not permit a more lengthened attention;\* we cannot, however, omit his notice of Berzelius's opinions on the nature of the "haloid" salts.

\* *Acids.* Aspartic, amylic, chlorous, ceric, hippuric, indigotic, pyrophosphoric. Agedoite, alizarine, corytalen, coumarin, pluranium, rhenium, sanguinaria. To these we may add his account of the modified opinions of the nature of the caseous principle of milk, the confirmation of the existence of the metal thotinum, and the controversion of Taddei's opinions concerning gliadine and zymome.

"*Haloid Salts.*—This term comprehends all those compounds which consist of a metal on the one hand, and of chlorine, iodine, and the radicals of the hydracids in general, excepting sulphur, on the other. The word *haloid*, being derived from ἅλς, sea-salt, and εἶδος, appearance, is very appropriate, since the substances to which it is applied, such as the chlorides and iodides, cannot in many instances be distinguished by their aspect from real salts; but in point of composition they resemble oxides rather than salts, and in connexion with these they have already been described.

"Berzelius has correctly remarked, that the number of haloid salts which a metal is capable of yielding with the same element, generally corresponds to the salifiable oxides which it forms with oxygen. Thus, there are two chlorides and two iodides of mercury, proportional to the two oxides of mercury; and potassium, which has but one salifiable oxide, unites in one proportion only with chlorine and iodine. Besides simple haloid salts, Berzelius distinguishes three different combinations of them. The first of these is an acid haloid salt, formed of a simple haloid salt and the hydracid of its radical. A compound of the kind may be obtained by evaporating a muriatic solution of gold with excess of acid at a very moderate temperature, when crystals are obtained, consisting of chloride of gold and muriatic acid. The compound of fluoride of potassium and hydrofluoric acid offers another example. These compounds may be called *hydro-haloid salts*. The second mode of combination, which is more frequent, gives rise to what may be termed *oxy-haloid salts*, being composed of a metallic oxide, united with a haloid salt of the same metal. Thus chloride of lead combines with oxide of lead; and submuriate of iron, obtained by evaporating permuriate of iron in an open vessel by a rather strong heat, is considered by Berzelius as a similar compound. The third kind of combination is productive of double haloid salts. They may consist, first, of two simple haloid salts which contain different metals, but the same non-metallic ingredient, as the double chloride of potassium and gold, or the double fluoride of potassium and silicium; secondly, of two haloid salts consisting of the same metal, but in which the other element is different, as the compound of chloride of lead with fluoride of lead; and, thirdly, of two simple haloid salts, of which both elements are entirely different. In some cases haloid salts unite with common salts; as, for example, when chloride of sodium is fused with carbonate of baryta, or carbonate of soda with chloride of barium."

Having spoken thus favourably of the work, we have to notice an error or two of

omission, with some trifling faults of commission,—blemishes which we regret to observe in a book which we should otherwise have designated as perfect in its kind. Why, we would ask the author, has he passed over, in silence, the beautiful and talented papers on galvanic subjects, by Mr. Kemp, of Edinburgh, published in the new and clever “Journal of Natural and Geographical Science” in that city? Was it fair, or candid, to pass by, thus contemptuously, the labours of a young but highly promising chemist, whose papers have been translated into more than one of the foreign scientific journals? Dr. Turner cannot plead ignorance, nor will he venture to deny the importance, of Mr. Kemp’s experiments. We cannot account for the circumstance, except on one supposition, in entertaining which we hope we should wrong Dr. Turner. Again; we find that Dr. Turner has taken no notice of papers published in *THE LANCET*, pointing out a remarkable error in the tests advanced for nitric acid; the author still recommends the sulphate of indigo, although its utter fallacy has been indisputably established; we pass over this, however, the more superficially, as our own Journal is concerned in the omitted facts. The important discovery of salicine, moreover, is omitted, though certainly there was quite time enough to have alluded to it in the appendix, if not in the body of the work. We are also compelled to notice the inadequate, we had almost said discreditable, manner, in which electro-magnetism is disposed of, a subject which, in scientific importance, is perhaps unequalled at present, and which, from every other chemist, from Henry especially, has received the attention which it so signally demands. Lastly, we must allude to the brace of laughable plates which terminate the volume; our readers will scarcely believe it, but let them examine, and they will find that Dr. Turner has considered it necessary (3rd edit. A.D. 1831) to present them with a drawing of—a safety lamp and a pestle and mortar! A retort stand, an evaporating dish, and a Hessian crucible, are also figured with the most amusing solemnity. Such are all the faults which, we believe, Dr. Turner’s *Elements* contain; there are, however, some typographical errors which have run through each edition, and some of which are by no means unimpor-

tant; thus at page 351, alcohol is stated to be composed of 14, or one equivalent of “oxygen” gas, united with 9, or one equivalent of water, instead of 14, or one part of “olefiant” gas, &c. This error we have known to create a considerable impediment to the understanding of the compounds of carbon and hydrogen, and their atomic relations.

In conclusion, it is but just to say, that these faults are few and trifling indeed, when contrasted with the numerous excellences of the work; that, on the whole, we consider it the best *elementary* book on chemistry in any language with which we are acquainted, and that all the errors are shared by every contemporary publication, without many of the redeeming features by which this is distinguished. It is only because we expected the nearest approach to perfection from Dr. Turner that we have alluded, thus specially, to these particular omissions.

## ST. THOMAS’S HOSPITAL.

### CLINICAL LECTURE

DELIVERED BY

DR. ELLIOTSON,

Nov. 29, 1830.

In the enumeration of cases admitted and presented, with a brief summary of which the present lecture was prefaced, was one of rheumatism of the chest and one of inflammation of the spine, both of which were cured by the application of leeches to the region affected; one of chronic inflammation of the hip-joint, following a sprain of six months’ duration, with numbness and, occasionally, acute pain down the front of the thigh, which was cured by the vigorous application of cupping-glasses and making his mouth tender, and one of an uncertain nature, in which the upper part of the man’s abdomen was tense, hard, and very large, affording a little fluctuation, which was relieved by active purging and friction with hydriodate of potash, in the form of ointment, a very useful salt, Dr. Elliotson observed, in many enlargements of the abdomen and other parts.

#### COLIC ARISING FROM LEAD.

In William’s Ward was a very good case of colic from lead, which was treated very

simply and cured. The man's name was Thomas Passmore; he was aged 52, was admitted on the 4th, and presented on the 25th of November. He said that he had been ill a month, had had no stool for three days, and, indeed, had never had a stool oftener than that during the whole month. He was labouring under vomiting and violent pain of the abdomen, such as is vulgarly ascribed to a twisting of the intestines—*tormina*; on pressure, however, there was little increase of pain, or rather, indeed, some portion of the pain was diminished. But besides the pain, which thus appeared to be of a spasmodic character, there was tenderness. The tenderness was inconsiderable, and on making pressure he experienced considerable relief, though he felt soreness; the case, therefore, was, no doubt, much more one of spasm than of inflammation, though it partook of both. The pain was greatest about the umbilicus. He had had no sleep for some time, in consequence of the pains in the back and limbs. This is a fact worthy of notice. The pulse was only 72, and was full and soft; material inflammation, therefore, was out of the question, and the principal part of the affection evidently consisted in spasm. His face was not flushed, and his skin was cool. I asked him if he had been exposed to lead, to which he replied in the negative, and I, of course, could not say that he was not speaking the truth. I gave him a scruple of calomel, and ordered him to take half an ounce of castor oil every two hours afterwards, till he was purged. He said at night that the pain was more severe, and that he had had no motion. The gentleman who saw him in the evening gave him another scruple of calomel and a grain of opium, this being followed by castor oil; his bowels then became opened, and two stools occurred.

It is the custom of many excellent practitioners to give opium in large doses at the first, with the purgatives, and I have no doubt that it is a very good practice, provided you give purgatives briskly, for the opium can then do no great harm, and possibly may do good; it may, in fact, act indirectly as a purgative, by lessening the spasm. This, I believe, is almost the only instance, except in the case of extraordinary idiosyncrasy, in which opium opens the bowels; but still, in this disease, the ultimate effect of opium is to leave the bowels more contracted than before, and therefore I am not in the habit of employing it. I think I have found that the cases do as well when you give simple purgatives as when you administer opium. I am not, however, speaking decidedly on this point. I have not compared a sufficient number of cases to say whether simple purgatives, or their union with opium, will answer best; but so far as my

observation has hitherto gone, I believe that full doses of purgatives will answer as well without opium as with it; and as, although opium may do good in the first instance, there is a chance of the bowels becoming more sluggish afterwards; I have fallen into the habit of giving purgatives without it, and my cases do just as well as the cases of those who give opium in addition.

However, this man took opium but once, and then only one grain, so that no inference can be drawn from this case; he took forty grains of calomel, and two or three ounces of castor oil: all this medicine opened his bowels, and he got the better of the spasm; but now more or less of an inflammatory state came on in a decided manner. There was tenderness of the abdomen; a severe pain down his thighs; the tongue was brown, and his face became flushed. It is also to be remembered, that he said he had a fall upon the abdomen six years ago, which of course rendered the abdomen more liable to inflammation on the application of an exciting cause. I found it necessary the next day to bleed him to syncope, to put on twenty leeches, and to follow that by a poultice of bran. It was necessary, in two days, to apply twelve leeches to the abdomen, and after the application of these he did very well.

For opening the bowels in colic, I believe one of the best plans is to give a large dose of calomel, say a scruple, for securing the operation of other purgatives to be given in repeated doses subsequently. A large dose sits on the stomach as well as a small one, and does not operate violently. An injection of three ounces of oil of turpentine at the same time is very useful; this medicine might be given by the mouth, like the other purgatives. When all things fail, dashing cold water on the belly and legs has often succeeded, just as it sometimes does in spasmodic retention of urine. The introduction of tobacco-smoke into the rectum ought never to be omitted, when the case proves rebellious to ordinary measures.—There is a little apparatus for this purpose; but when faintness and the pulse show the system to be influenced, you should desist from the insufflation, and after a time, if the bowels do not relax, repeat it. Sydenham had so high an opinion of this in constipation, from his experience, that he says,—“*Ego fumum nicotianæ sive tabaci ex tubulo inverso per vesicam majusculam in intestina validissime insufflatum, enema omnium quæ mihi innotescunt hactenus, efficacissimum esse duco.*”

After his colic and inflammation were cured, he had severe pains in his limbs, for which he employed the hot bath, and that quickly and entirely removed them. Now the occurrence of these pains strengthened

my original suspicion, that the man had been in the way of lead. When colic occurs from cold, or an obstruction in the intestines within or without (for any thing that obstructs them will cause colic, whether, for example, it be the pressure of a strictured abdominal opening in hernia, or a collection of hard faeces within), whatever causes it, if it be not lead, there is seldom pain in the back and in the extremities. The occurrence of pain there in the first instance made me ask whether he had not been in the way of lead, and he denied that he had; but when I saw, after the colic was gone, that the pains were severe in the extremities, and that the warm bath took them away, I had still stronger suspicions, and questioned him over and over again, till at last he said he had been engaged in painting a ship (he was a seafaring man), but could not have supposed that that produced the colic, or he would have said yes when I questioned him. Patients will continually tease you in this way; they will not give a plain and true answer, but will be guided by what they think. Although he had been in the way of lead, yet, because he thought it could not have hurt him, he denied it altogether. This is a difficulty that you will every day meet with in investigating cases. Although, however, he had only been engaged one day in painting the vessel, he had of course been exposed to the effluvia of lead afterwards till the paint was dry. This exposure had occurred, he said, some little time before the colic began, which might be correct, but the exposure might have left a disposition to colic, and then an accidental cause might have brought on the complaint. This is just what we see in ague, where persons have been exposed to malaria. Ague frequently will not appear at the time, but the tendency to the disease, nay, perhaps the poison itself, being in the system, the persons will go on for a long period, perhaps several months, when the disease will appear if they take cold. So it might have been with this man with regard to the lead; accidental circumstances might have acted upon the predisposition acquired by his exposure to the lead. When colic arises from lead, it is often preceded, accompanied, or followed, by those severe pains in the loins and extremities. When you give lead internally as a medicine, you will find that if you are obliged to administer it in large quantities, the most severe pains of those parts will sometimes result. You may keep the bowels open during the exhibition of the superacetate of lead, and prevent all colic, but frequently severe pains in the extremities come on afterwards; these are best removed by the warm-bath, or by colchicum, but I believe that the warm-bath answers better than any thing else. It is among the peculiar effects of

lead to produce violent pains in the back and the extremities. There is another observation to be drawn from the consideration of this case, namely, that although colic is a spasmodic complaint, it is very liable to become an inflammatory one; it is very liable to become enteritis. We see this every day in colic from strangulated hernia. The symptoms are at first colic; the pain comes and goes, and there is no pyrexia; but after a time, sooner or later, you have tenderness of the abdomen, with all the marks of abdominal inflammation, and, ultimately, mortification. It is just the same with colic of all kinds; if there be the least obstruction, and it is unremoved, inflammation is sure to appear: and even if it be removed, if this is not effected in good time, inflammation may still come on. Here the disease had lasted, more or less, a month, and the opening of the bowels did not prevent inflammation; indeed, that which was mere tenderness—slight tenderness of the abdomen on the first day that he came to the hospital, soon became extreme tenderness; his pulse got up, his face became flushed, his tongue brownish, and it was necessary to bleed him. Independently of this, you will often find it useful to bleed in colic, just as in the early stage of strangulated hernia, or spasm of any sort throughout the body; for relaxation of spasm is often effected by bleeding. If the pulse be full, and the person strong and in the prime of life, it is often a good practice to bleed; it produces relaxation of the whole frame, and, consequently, relieves the parts that are in a state of spasmodic contraction among the rest. This is a good practice also on another account; it tends to prevent inflammation; though the moment signs of that appear, you ought to treat the disease as one of an inflammatory character. If the colic had not presently yielded, I should have bled this man; and although it did yield, yet, as tenderness increased, I lost no time in bleeding him the next day. It is also to be remembered in colic, that no antiphlogistic measures can do good if the obstruction continues in spite of them and other means, for it keeps up the inflammation. I recollect being called to a man twelve months ago, who was labouring under a dreadful colic after drinking a quantity of rum. The pain was much diminished by pressure; pressing with the whole weight of my body on the abdomen with both hands lessened his pain materially, but his obstruction never gave way. Oil of turpentine was given both by the mouth and the rectum, and every sort of purgative was administered; opium was also given in full doses, but none of these produced any effect; none of them would open his bowels. Inflammation supervened, and

he died. It appeared that this colic came on in a moment, and, by post-mortem examination, it was found that one portion of the intestine had passed within another; intussusception had taken place, and adhesion had thus occurred around the intussuscepted part, the intestine was completely obstructed, so that nothing, of course, could have relieved his complaint short of opening the abdomen, and operating upon a portion of the intestinal tube. This, however, could not have been effected in the present instance, because there was no greater indication of an obstruction in one part of the abdomen than in another; there was no pain in one spot more than another—no tumefaction or induration. Although some surgeons have performed this operation, it is a practice that one would hardly be inclined to adopt, unless in some rare cases where the situation of the obstruction was very clear, and the person in certain danger, though without having sunk too far.

#### SCARLATINA.

There was likewise presented in William's Ward a case of scarlet fever, affording a very good illustration of that disease, and of the treatment which it is best to adopt for so guiding the disease that it may go on mildly and torment the patient but little. Like most of these cases, it occurred in a young subject, a boy named James Harris, ætat. 10, who was admitted into William's Ward on the 11th of November. He had been ailing for a month, but on the 9th of November was seized with rigours, which were followed by heat, pain of the head, and sickness. On the 10th, a redness of the skin was observed about the chest, which on the 11th, the day of admission, had extended over the whole body; and the day the affection appeared, he complained for the first time of a sore throat, and there was, at his admission on the 11th, an ulcer on one tonsil, covered by an ash-coloured tenacious exudation, such as is generally considered a slough. The tongue was tremulous, and red round the edges; the pulse frequent and small, as much as 150; he complained of pain in the forehead, sickness, and heat, with great thirst; the bowels were rather confined.

You know that scarlet fever belongs to the exanthemata of Dr. Willan; that it is a disease which occurs only once, and affects children particularly. I believe its recurrence in the same person is not more frequent than the recurrence of small-pox or measles. Dr. Willan says, that among two thousand cases he never saw it occur more than once; but that it does recur, the same as measles and small-pox, is undoubtedly true. There are exceptions to this

very general rule. Many persons are insusceptible of this disease, not merely adults, but children. Many children who are as much exposed to it as others, never have it. I myself have never had the disease, though continually exposed to its infection, and there are hundreds and thousands of others who have not, although, like me, they have gone through the common diseases incidental to childhood, such as small-pox, cow-pox, chicken-pox, whooping-cough, and measles. It is thought that children are more liable to this affection than adults, but I do not know that this is quite proved. In childhood, as much as at any other period, we are exposed to the contagion, and are therefore as likely to catch it then as at another time; and, further, as when we have had it once we cannot have it again, adults, for the most part, must escape, without the disposition to it being at all greater in infancy than afterwards. If you suppose an equal susceptibility of the disease during the whole of life, as all are exposed to its infection from infancy upwards, and scarcely any have it a second time, of course the greater number of instances of the disease must occur in children. Scarlet fever is not by any means so usual a complaint, whether in children or adults, as the measles and small-pox.

It is not certain what is the period that elapses between the application of the contagion and the appearance of the disease. I believe, with respect to all contagions whatever, that there is a great variety of periods, and I do not think that there is a rule for any of them, because where we can make accurate observation, as in gonorrhœa and syphilis, we see that there actually is a great variety. Scarlet fever is said to appear in general within four or five days after the contagion has been applied. The interval is longer, generally, in adults. It is not exactly known how long a person is capable of communicating the contagion after he has had the disease; perhaps not longer than two or three weeks, unless desquamation of the cuticle continue; and then the exfoliations appear to be so impregnated with the poisonous secretion of the skin, that they may give it as long as they continue to be formed. How long they may retain the contagion after separation, I do not know.

The disease usually begins, as it did in this child, with a feeling of general illness, pain in the head, and chilliness, which are soon followed by heat, thirst, and sickness, and all the symptoms of pyrexia. There is this difference in the early period of this disease between it and small-pox, that in small-pox there is frequently intense pain in the loins, sometimes dreadful pain, especially in adults, such as would almost make you fancy an inflammation that might

induce suppuration; and great tenderness of the epigastrium,—symptoms which do not occur in scarlet fever. If a person, therefore, be taken ill suddenly, and you suspect the appearance of an eruptive disease, and yet there is no violent pain of the loins, and no extreme tenderness of the stomach, you have not the least reason for supposing small-pox. In measles, before the eruption, there are generally catarrhal symptoms. You see the eyes running; you hear the patient sneezing and coughing; the whole face is flushed, and the head very heavy. This is not the case in scarlet fever, which does not so much affect the conjunctiva and the air passages, whether the nostrils, larynx, or bronchia, as do the measles: there is nothing like catarrh; and, therefore, when you see violent symptoms of that, you may suppose that the disease will be measles, and not scarlet fever. When the eruption has begun a short time, there generally can be no doubt as to its true nature; minute red points appear upon the face and neck, extremely small; they soon become innumerable, run together, and within twenty-four hours, form continuous patches over the trunk and extremities; the patient then looks very like a boiled lobster, or as if he had been smeared with raspberry-juice; it is a bright scarlet colour, that does not appear in measles, or in any other disease; the hue is most vivid at the flexures of the joints and in the loins; the efflorescence is especially continuous round the fingers, seldom so much so on the trunk. The skin altogether is smooth in this disease; but if you examine it very accurately, you will find exceedingly minute asperities, like the *cutis asperina*, where the skin is naturally rougher than in other parts. The small points of the skin become a little inflamed, and, consequently, there is not a coarse roughness, such as may be felt in the face, under measles, but a minute roughness, which may just be felt with the very ends of the finger; but for this, you might say, that there were merely red patches of the skin.

You are not, however, to suppose that what are called cutaneous diseases are mere diseases of the skin; they are all called cutaneous diseases, it is true; but it would be wrong to suppose that these diseases are limited to the skin. In measles, the mucous membrane of the nostrils, the conjunctiva, the mucous membrane of the air-passages, often down to the very air-cells,—nay, occasionally the substance of the lungs and the pleura, and even the intestines, are much affected. In small-pox there is often great affection of the larynx,—such as frequently destroys life; a great affection, also, of the epigastrium; the stomach is particularly tender, and is really inflamed from the

very first. So in the case of scarlet fever, you are not to consider it a mere disease of the skin; it certainly does not much affect the eyes or the nose, but it does affect the inside of the mouth, the tonsils, the velum pendulum palati, the pharynx, and the tongue, often most intensely. These symptoms are more or less observed in almost every case, and in some instances the parts are affected to a violent degree, so that, indeed, their state particularly co-operates in causing death. There is sometimes, likewise, in this disease, an inflammation of the stomach and intestines; the mucous membrane of the alimentary canal is affected below the pharynx, so that there is tenderness of the epigastrium; and sometimes there is, as I shall presently mention, inflammation of the head, inflammation within the chest, or lungs, as well as in the abdomen. In all these diseases, the inside of the head often suffers extremely; more or less inflammation occurs there. These are really diseases of almost the whole system.

The case which I have now mentioned was one of that form of the disease called *scarlatina anginosa*. There are three forms of the disease, the first of which is *scarlatina simplex*, in which the skin only is affected, or, rather, the affection within the mouth is inconsiderable, not worthy of notice. In the second variety the throat is affected considerably; hence it is called *scarlatina anginosa*. If this occur, which it sometimes does, with a disposition to mortification, the disease is then called *scarlatina maligna*.

The present case was one of *scarlatina anginosa*; it was a mild case, but still it affected the throat, not, however, very severely. It is generally on the second day of the person's illness that the eruption comes out, and it generally lasts a week altogether; on the fourth day of the whole disease the affection is at its height; about the fifth it declines, so that interstices and patches reappear; about the sixth there is an indistinct eruption only; on the seventh it is usually gone before the end of the day; and on the eighth and ninth the cuticle is seen coming on. In the mildest form of the disease the tongue is red, but if there be much inflammation of the mouth,—that species of the disease properly called *scarlatina anginosa*,—you see the tongue not only red, as if the mucus upon it were sprinkled with grains of cayenne pepper, but the papillæ are so elongated, as well as red, as to project considerably through the mucus. The tonsils, and the velum pendulum palati, are entirely red, and you see them covered here and there by dirty exudations or sloughs; these, of course, vary in quantity, so that between them and the tumefaction the patients can sometimes scarcely swallow or breathe. It is dis-

eased mucus in the one case, and when removed you see the inflamed surfaces below; when it is a real slough an ulcer is seen on its removal, that is, in the anginosa, when the inflammation of the throat is intense. In this state the general symptoms are much more severe; there is more shivering at first, and afterwards more intense heat of the body. The heat is so intense as to be at  $107^{\circ}$ ,  $108^{\circ}$ , or  $111^{\circ}$ ; but even in the mild form of the disease, where the throat is scarcely affected, you will find the heat very intense. The eyes, too, are affected, and so is the nose, but to nothing like the degree that you see in measles, though sometimes the face so swells that the eyes are closed. It is observed in this form of the eruption that it does not come out on the second day, as in the mild form, but at a later period; nor does it fully come out: it comes and goes, and the disease does not terminate so decidedly altogether; the desquamations will continue for some weeks. In this extreme form of the disease the symptoms are all severer from first to last. When there are symptoms of great malignity, there are signs of great debility; the throat is in a state of dark sloughing, mortification takes place, and the most putrid smell is perceived, and, for the most part, the patients die. Now, in the case under consideration, one ulcer occurred upon the left tonsil. When the ash-coloured slough was removed, an ulcer appeared under it.

The treatment consisted simply in keeping the patient clean and cool, and in giving him scarcely any thing to eat. You will find a great number of cases of scarlatina do perfectly well if no medicine be given. This is almost always the rule of treatment. Keep your patient clean and cool, and equally avoid internal stimulants, by giving him as little food, and that as little nutritious as possible. Thus treated, he is almost sure to do well. You will hear persons say that they have given a particular medicine in two or three thousand cases, and these have all done well; and another will say the same thing with respect to some other medicine. I have no doubt that if they had given no medicines the cases still would have done well, provided the patients were kept clean and cool, and given only diluent drinks. There can, however, be no doubt of the propriety of *one* sort of medicine, and that is aperients, because an open state of bowels very much lessens the general irritation of the system, by the removal of the unhealthy and disordered secretions which it necessarily produces, and by gently evacuating the vascular system; but I believe that is all that is required in by far the greater number of cases. There was at one time a great antipathy to purgatives, founded on the supposition that they were ex-

hausting. It is remarked by Dr. Bateman, that the patients were first exhausted by the treatment adopted, that fires were lighted in the rooms, the doors and windows were kept shut, additional clothes were put upon the bed, and the patients were kept in such a state of heat and excitement, and so much exhaustion was produced, that purgatives became really hazardous. Moderate purgatives, however, are all that are requisite. You must carefully open the windows and doors, according to the season of the year, and let the patient be but lightly covered. This patient was at first washed several times a day with cold water, and afterwards with tepid water. There is no objection to the application of cold affusion, if you ascertain that the temperature is steadily above  $98^{\circ}$ , or, indeed, if the patient merely says he is hot. By merely cold water you will induce perspiration better than by other means, and you will sometimes, it is said, cut short the disease altogether. It is not, however, an object to cut short the disease, because if you so put an end to it, the patient will most likely have it at another time, and as the disease is begun he may as well go through it: the object is to lessen, rather than remove it. But whether you use cold affusion, or cold ablation, or tepid affusion, or tepid ablation, you will find that the practice is exceedingly beneficial. I never omit the use of water, if the patient feel hot, and be not in a profuse sweat. I do not use cold affusion, because I find cold, or tepid, ablation answer the purpose; but in every case of this disease, where the heat is above the natural standard, I have the patient washed several times a-day, as long as the heat continues, with either cold or warm water, whichever he prefers. I never yet lost a case of this disease.

It is to be regretted that the French do not seem yet to know the value of cold water in fever. M. Rayer, whose work on cutaneous diseases, coming after Willan's, and founded to a great extent upon it, is altogether a far better and more copious work, says that the application of cold water to the surface is too much extolled by the English, and that we should not go beyond wetting the epigastrium. Yet he acknowledges that he has *never* dared to employ it as directed by Currie, Withering, Bateman, and others. I know that it is not at all too much extolled; and the comfort of cold ablation, to say nothing more of it, is indescribable. It is our neighbours' fancy that it may produce anasarca. It might, if employed when unnecessary, that is, when the skin is not hot and dry, and anasarca generally follows this disease when the patient has been improperly exposed to cold, and especially to cold and wet; but so absurd a misapplication of

a remedy is no argument against it. No remedy is really a remedy, but when well-timed; *nullum datur remedium quin solo tempestivo usu tale fiat*. I have seen incalculable good from cold and tepid ablu-tion, but never the slightest harm.

Abstinence from food is of the greatest importance: you should give nothing but tea, barley-water, and similar diluents. Bleeding generally, and particularly locally, from the head, throat, chest, or abdomen, is sometimes required. When the throat is affected, you will find that one of the most useful applications is the chloride of soda or lime. This was used in the present instance around the bed; but you will find it one of the most serviceable gargles that you can employ. You must remember, however, that children cannot gargle the throat, and sometimes adults are in such a state that gargling is out of the question; in such cases you must apply it by means of a syringe, squirting it all over the mouth and fauces: this should be done every hour or two: the solution should be diluted, so as not to produce pain; I have continually employed it for the last two or three years, and certainly with the most beneficial effect. It comforts the patient; it causes the ulcerations to assume a healthy appearance, and throws off the sloughs. It is of great use also to employ the chloride of soda or lime about the bed; but the latter generally is used for these external purposes. It would appear that the chlorides of lime and soda have a tendency to destroy contagion, and on this account I sprinkle one of them upon the bed-clothes, have it thrown upon the removed linen, place it in saucers around the bed, and introduce it into the vessels which are used by the patient for the purposes of nature. Were it only to lessen fevor, its use in every sick room in the latter mode is a great comfort. I adopted the practice in this case because I knew that this was an infection which is particularly apt to spread, and because so many children are always in the hospital. I recollect the circumstance of a patient being admitted into a ward with scarlet fever, and children and young men in that ward, for nearly two years afterwards, were continually seized with scarlet fever, notwithstanding the hospital is thoroughly whitewashed and cleaned once a year. Where malignant symptoms come on, it may be necessary to use the treatment that is adopted for typhus fever. But it is frequently necessary to apply leeches in this form of the disease, on account of local internal inflammation. There is, however, another thing to be remembered in connexion with this affection, namely, that after it has gone through its stages, the patient is very liable to dropsy. It is a singular circumstance, but one well-established,

ed, that after scarlet fever, children are apt to become anasarcaous; nay, sometimes more than anasarcaous; to have effusion into the head, chest, or abdomen. I believe this occurrence takes place much more frequently in winter and in cold damp weather, than at any other time. Hence, allow me to repeat, that however proper cold affusion, or cold ablu-tion, may be, when the temperature is above the natural standard, yet, when the heat is not above the natural point, and after the disease is over, there would be the greatest danger, no less than perfect inutility, in their application. I believe the dropsy that occurs after this disease is almost always of an inflammatory nature—that there is either a general inflammatory state, or a local inflammation. As in other inflammatory dropsy, the face is affected at the very first. I believe that when effusion occurs in the chest there is inflammation or sub-inflammation of the pleura; and so with respect to the abdomen, there is peritonitis; and with respect to the head, arachnitis; or at least the state of these parts is inflammatory. I believe that this dropsy is best treated by purgatives, and by leeches applied to the parts in which it particularly occurs, whether the head, the chest, or the abdomen. If there be hydrocephalus, or ascites, or hydrothorax, or if there be not—in all cases purgatives are the best remedies, adopting local bleeding if you find local dropsy, and having recourse in intense cases to bleeding from the arm. It is said that digitalis answers a good purpose, that it controls the pulse, that it excites the secretion of urine, and that it lessens the inflammation altogether. Many cases do well with slight or even without any treatment; but I believe the best general rule is to treat the disease in the first instance, if this be not counter-indicated, on the anti-inflammatory plan.

ON THE USE OF  
THE STETHOSCOPE  
FOR THE DETECTION OF  
PREGNANCY, A FÆTUS IN UTERO, &c.

By DAVID C. E. NAGLE, A.M., M.B.,  
Trinity College, Dublin.

“Ου χρεῖ παννυχιον εἶδεν βουλευφορον  
ανδρα,  
ὃ λαοι τ' ἐπιτετραφαται, και τοσσα  
μεμηλε.”

—

“It had never occurred to me (said the illustrious Laennec) to apply auscultation to the phenomena of gestation. For this happy idea we are indebted to Dr. Kergaradec,

who obtained by it two results, which may now be considered as the most certain signs of pregnancy, namely, the pulsations of the fetal heart, and the simple blowing pulsation (*battement simple avec soufflet*), or placenta sound."

It may, perhaps, be considered presumption in me to differ in opinion from authority so weighty and influential with medical men as that which is supported by the names of Laennec and Kergaradec. But when I venture before the profession with views that, to many of its members, may appear both novel and untenable, I hope they will extend to me all the indulgence which should be awarded to one who really has no object in view but the advantage which may arise from a fair and candid examination of opinions and doctrines which appear to him to be erroneous. With much reluctance, indeed, should I attempt dissenting from any opinion offered by the talented Laennec, as the result of his *own* observation and experience; but when I reflect that, in midwifery at least, he must necessarily have had but a very limited experience, I feel sufficient justification for not fully coinciding with the inferences which he drew from Kergaradec's researches.

In a paper which I laid before the public in a late Number of *THE LANCET*, I considered auscultation to furnish us with the most and the only unequivocal sign of pregnancy, in so far as it enables us to hear the pulsations of the fetal heart, from the moment that it begins to act with any degree of energy; but I must be pardoned if I withhold my assent to the importance of the other phenomenon laid down by Kergaradec as a sure sign of utero-gestation. I perceive, with regret, indeed, that in the "*Dublin Medical Transactions*," lately published, Dr. Ferguson concurs in opinion with Kergaradec, that the "*placental bruit*," as the former designates it, should be considered as "*infallible evidence of a fœtus in utero*;" and opposed as I am to such physicians as Laennec and Kergaradec, I hope my young and intelligent countryman, who himself admits that he has had but a very limited acquaintance with midwifery cases, will pardon me for a disagreement in opinion with him too, when I submit that we are not justified in placing any reliance on what is usually denominated the "*placental soufflet*," as an unequivocal sign of impregnation. In justification of this assertion, I trust I shall succeed in laying before the profession sufficient proofs and the most convincing facts.

During my attendance at the excellent Meath Hospital, I endeavoured by much industry and minute attention to the diseases of the chest, to familiarize my ear to the nicest distinction of the rôles and sounds

afforded by disease. Prepared as I must thus have been for the detection of the stethoscopic phenomena presented by gestation, I entered, from my very commencement at the Lying-in Hospital, on the investigation and analysis of those phenomena. The result of some of my inquiries I shall now endeavour to submit to the profession.

I have already stated that the simple blowing arterial murmur, designated by some "*placental soufflet*," heard in the advanced stages of utero-gestation, should not be considered as an unquestionable sign of impregnation, and I trust I shall show by most satisfactory proofs that it is wrongly denominated *placental*, the placenta in my mind having nothing to do with its production. The contrary opinion I know is confidently maintained in a paper published in the last volume (5th) of the "*Dublin Hospital Reports*," by Dr. Kennedy, for whose understanding and industry I entertain so much respect, that I should be sorry even to insinuate that in his hands the stethoscope should be considered as an "*inutile lignum*."

In the appendix to Laennec by Forbes, 2d edit., p. 703, it is stated that "*the bellows sound*" is usually heard "*on the side opposite to that on which the fœtal pulsation is perceived; but this is by no means constant*." The latter part of this extract is, I humbly submit, the only portion of it deserving our attention; for in some hundreds of cases in which I carefully examined this phenomenon, I have, in ninety-nine instances out of every hundred, heard it as well on the one side as on the other in the same patient. It may, I admit, be masked on one side in some degree by the pulsations of the fetal heart; but an acute and practised ear will experience no great difficulty in detecting it even then. The great and unusual difficulty is, to find a case where it is really confined to one side. Whenever I happened to meet with any want of facility in detecting this sound during the day-time, I returned to the examination in the stillness of night, and generally heard it without much trouble, noting carefully that it was not that which proceeded from the opposite side.

When the patient is placed in the recumbent posture, with only a sheet interposed between the sternal extremity of the stethoscope and the abdomen, the auscultator will in most cases detect the soufflet at a point midway between the umbilicus and the superior anterior spinous process of the ilium, but not unfrequently closer to the latter. It often extends from this point towards the middle of Poupart's ligament, the loudness of the murmur in many cases increasing in a very marked degree as we descend; yet it not rarely assumes near the

gament a sharper character. From the same point it can often be traced upward and forward towards the mesial line, in the course, as it were, of the *trunk* of the *lateral* uterine arteries, which, it must be remembered, is enormously enlarged in the advanced stages of gestation. Thus then, in most cases, the soufflet can be traced from the middle of Poupart's ligament to a point midway between the scrobiculus cordis and the centre of a line extending from the anterior superior spinous process of the ilium to the umbilicus; and, in general, it is at the same time audible on both sides. Of this I have had indeed many satisfactory proofs; for instance, in the first of the twin cases recorded in No. 376 of THE LANCET, in which case, while examining the patient, I pointed out the fact to Dr. Kennedy. To this circumstance respecting the sound I must beg leave to direct attention, while from the nature of the soufflet, and the extent of surface over which it could be heard, I endeavour to draw an argument against Dr. Kennedy's theory, that "the placental soufflet is heard indifferently over the abdomen," and that "it depends on the transmission of blood through the arteries of that part of the uterus to which the placenta is attached."

It will be recollected that in the above case of twins I stated that there was but *one* placenta. The patient having died, this was found to have been attached to the upper part of the fundus of the uterus, which, I also stated, was more than usually distended previous to delivery. Now, if the soufflet be owing to the attachment of the placenta in a case where it was thus affixed, it is very improbable that the soufflet could extend equally on both sides all the way down to the middle of Poupart's ligament, without gradually decreasing as we, in the descent of the cylinder, receded from the radiant point. Besides, when the cylinder was moved across any part of the abdomen from one side to the other, the soufflet could not be detected to extend *uninterruptedly*, even at the upper part of the uterus, as we might reasonably expect it to do, particularly when it was traceable down even to Poupart's ligament. We must therefore account upon other principles for the occurrence of the sound on both sides. Dr. Kennedy's expression, "heard indifferently," is so equivocal, that I am at a loss to determine the precise sense in which he meant to use it. If he means to imply, as I believe he does, that the sound can be heard, no matter what part of the abdomen we examine for it, the above case, and many others, will be directly opposed to him. In numerous cases I found the soufflet distinctly audible for a few square inches between the superior anterior spinous process

of the ilium and the umbilicus, but often approaching close to the latter, and it was even then quite perceptible in both iliac fossæ also. The question for us to determine in a case of this kind is, whether the sound on the opposite side is the effect of radiations from that part where the placenta *might* be supposed to have its attachment. Now the placenta was placed on that part, or it was not. If the placenta was placed on that spot, and thus gave rise to the soufflet on both sides, we might reasonably expect that this soufflet would radiate from one side to the other across the *anterior* surface of the uterus where the space must be narrower, rather than across the *posterior* wall where the greatest extension of the uterus is known to take place. Yet in no case was I ever able to trace it across the anterior surface of the abdominal parietes in an uninterrupted course, or even to detect it under the mesial line, except when it proceeded from the epigastric arteries, from which it can, in such a case, be easily proved to arise. But if the placenta was not situated on that part of the side of the uterus over which the murmur was so audibly heard, it will follow as a necessary consequence, that the murmur *there* must have originated in some other cause, an admission that would be fatal to Dr. Kennedy's theory, and the practical inferences he deduces from it. Now the cause of the murmur existing almost *invariably* in this spot, may, I conceive, be found greatly, nay chiefly, owing to the fact mentioned in his own paper, p. 239, that "in the neighbourhood of the ligaments, at the lateral parts of the uterus, we shall also find a *more full distribution of vessels*, even when the placenta is not attached to this part, as the principal vessels which connect the uterus with the maternal system pass into it *here*." To this fact I beg particular attention, as it is calculated very much to facilitate the settlement of the disputed question respecting the *site* of the murmur, and, consequently, whether, as we shall have occasion to discuss hereafter, the discreet and guarded practitioner would, without any other sign, be warranted by any change in the quality of that murmur alone, to pronounce on the life or death of a fœtus in utero.

Another position of Dr. Kennedy is, that when the soufflet is heard over the whole uterus, the placenta is then attached to the anterior wall of the organ. It will be easy, I think, to prove that this inference is unfairly deduced. In such a case the soufflet would be more distinctly audible, in proportion as we approached in our examination to the point of insertion, whereas the contrary is the fact; for the more we recede from the mesial line towards the iliac fossæ, the clearer, as far as my experience at least

warrants the assertion, does the murmur invariably become. Now let me suppose that the placenta is situated under the mesial line, what should we expect? Why, that the soufflet would be most distinctly audible over a space coinciding with the diameter of the placenta, and become fainter and fainter as we receded from that point of radiation. But I have already shown that the contrary is the fact. The same mode of reasoning will apply if the placenta be situated on the fundus of the uterus, for the murmur is generally heard louder at a point which is nearer to the pubes than to the fundus of a distended uterus.

In order to meet some assertions of the French writers, it will be necessary to refer to page 703-4 of Laennec. There he says, "What seems to me most probable is, that the sound in question exists in the chief artery distributed to the placenta," and then alludes to a communication made to him by Dr. Ollivry, who is represented to have expressed himself to the following effect:—"The point where I had previously heard the blowing pulsations, corresponded exactly with the point in which the placenta was implanted;" and again; "A proof that the cause is what you have stated, is found in the fact that the sound ceases the very moment the umbilical chord is cut." In his opinion a very triumphant, but in mine "a very lame and impotent, conclusion." As Laennec has himself successfully ridiculed the "*post hoc, ergo propter hoc*" mode of argument, perhaps I shall be fortunate enough to meet forgiveness from some of those distinguished men whose doctrines I am thus presuming to impugn, if I submit that Ollivry's "*prope hoc, ergo propter hoc*" is equally inconclusive. The admirers of Drs. Laennec, Kergaradec, Ollivry, Ferguson, and Kennedy, will be startled, perhaps, when I assert that the "self-same" identical description of murmur or soufflet, which usually occurs in the advanced stages of pregnancy, is distinctly presented to the ear, when there is no fetal circulation at all going on—where there is or has been *no placenta*! And now for the proofs.

In the first place I shall venture to assert, that the fetal circulation has nothing to do in the production of the murmur in question; that it can and does exist with its characters unaltered, even when that circulation is destroyed, no matter for what length of time; and therefore that we are to attach no importance either to the soufflet, as an infallible test of gestation, or to Ollivry's assertion, that "the murmur ceases the very moment the chord is cut." I could adduce many cases in support of my assertion, but the following will, I hope, appear sufficiently decisive.

On the 27th ultimo, a patient was admit-

ted into the Lying-in Hospital with abortion threatening, in consequence of ill usage received about three weeks previous. My acute and intelligent friend, Surgeon R. Robinson, was engaged in examining, with the stethoscope, this woman when I entered the ward. He expressed a wish that I should examine the case, observing to me, that he could not hear the fetal heart, but could distinctly perceive, in the right iliac fossa, a murmur *prolonged*, and not by any means "*abrupt*;" "but if I am (said he) to be influenced in my diagnosis by the theory of Dr. Kennedy (the truth of which he knew me all along to deny in the most decided terms), I must, from the distinctness and prolonged nature of the murmur, conclude that the fetal circulation is still going on." I examined the patient, could detect no fetal pulsation, but heard, on the right side, the murmur as described; it was also audible in the left iliac fossa, but weaker than on the opposite side. Convinced that by this case too I should be furnished with a powerful argument against Ollivry and against Dr. Kennedy's theory, respecting the quality of the murmur being a test indicative of the life or death of a fetus in utero, I remained in the ward until about four o'clock that day, at which hour the patient was delivered of a fetus, very small, dead, and so putrid, that not only had the funis been divided, as it would appear, for some considerable time previously, but, as it was a breech presentation and the parts in a very undilated state, I had considerable difficulty during the extraction of the fetus to prevent its limbs from falling asunder. The patient was in about the seventh month of her pregnancy; had received, about *three weeks* before her delivery, an injury on the side (after which occurrence she did not feel the fetus to move in utero), and the suspicion of its having been three weeks dead was fully justified by its excessive putridity. It is important to observe, that the placenta, in this case, was very much impoverished, and its diameter not greater than that of the palm of an adult's hand. This case, then, proves, not only that the murmur is quite independent of the fetal circulation, but that persons, unaccustomed to accurate stethoscopic observations, would, if influenced by Dr. Kennedy's theory respecting the *quality* of the soufflet affording a sure indication of the life or death of a fetus in utero, be liable to fall into very serious and egregious errors, as, from the practical importance of the fact, I shall have to prove more fully in the subsequent part of this paper.

I shall now proceed in my endeavours to show, that the presence of a placenta is not necessary for the production of a murmur, such as we ordinarily hear in the advanced stages of gestation; and that we can detect

It, as in certain cases of disease, when there is, or has been, no placenta at all. Here I am perfectly at issue with Drs. Ferguson and Kennedy, who assume that the soufflet should be considered as a test of pregnancy. As subversive of such dangerous theory, I am happy to have it in my power to instance the following case, which Dr. Montgomery, Professor of Midwifery to the King and Queen's College of Physicians in Ireland, did me the favour of taking me to examine on the 18th inst., at Sir P. Dunn's Hospital, into which the patient, Ellen Corrigan, aged 40, was admitted about three months before. She had had but one child, now twelve years old, after whose birth the catamenia continued regular until about four years ago, when she was attacked with fever, after which they began to exhibit some irregularity in their quality and the period of recurrence. Immediately after the fever, she began to suffer from weakness and sickness of the stomach which lasted six months, when, for the first time, she observed in the left iliac fossa a tumour, a hen's egg in size. This tumour repeatedly produced a lancinating pain that would frequently dart across the abdomen to the opposite side, to which, with a convulsive effort, she would apply the hand to arrest as it were the pain, and grasp the tumour that, she fancied, had shot across from its usual situation. The menses, she states, continue pretty regular and natural; the tumour is subject to great variety in size, and at present exhibits many of the characters observable on the abdomen of a woman in the seventh month of her pregnancy, and indeed the female has often been suspected of being pregnant. The *right* lower extremity is frequently more swollen than the left, and the veins are described to have been in a very enlarged condition. Such is the case I had to examine for the "placental soufflet" of authors; and in the right iliac fossa I detected, in the presence of Dr. Montgomery, an intense and lengthened murmur, which he also heard, and which, when the patient lay in the horizontal posture, I found to proceed from a point near the anterior superior spinous process of the ilium, upward and forward, towards the mesial line, as in cases of pregnancy. I then made the patient turn quite on the right side, so as to lessen, as far as can be done, the pressure on the left iliac vessels; yet the sound could be heard here, even in such a posture, without any material change in its character; so in like manner did I examine the right side, where the soufflet was invariably more intense than on the left. When she got into the erect posture, the murmur continued unaltered on the right, but became a little weaker on the left side. It is unnecessary to say that I examined with particular care this case, so

interesting, as far as the stethoscope, at least, is concerned. It was mentioned that the right lower extremity was far more swollen than the left, and that the murmur on the right side was louder than on the left. To a reflecting mind may it not appear, that these two circumstances might bear the relation of cause and effect to one and the same thing—increased pressure on the right iliac vessels, and, by a necessary consequence, an obstruction to the free transmission of blood through them?

To an unprejudiced person I would put the case thus. If the soufflet in question is to be considered an *infallible* proof of pregnancy, it can exist only where there is or has been a *placenta*. But I may be permitted to hope that the above case, of nearly four years' standing, fully justifies the belief, that we can have this murmur when there is no placenta. I therefore respectfully submit, that we should no longer deem it an infallible test of utero-gestation. Again; if the murmur depend on the presence of a placenta, it is only fair to infer, that its intensity, and the extent of surface over which it can be heard, ought to be in proportion to the size of the placenta; but I shall show that this proportion does not exist, and therefore the conclusion to which we ought to come must strike every unbiassed mind. First; in the second of the twin cases, which I lately laid before the profession, there were *two* placentæ, each of the ordinary size; yet I could not, by the most minute examination, detect, previous to birth, any alteration in the character of the soufflet. Again; on the 17th of September last, a female was delivered in the hospital of a healthy fœtus, whose umbilical chord, of the ordinary size and length, bifurcated within three inches of its termination in the placenta, and each branch was inserted into a distinct placenta of the usual size and consistence; yet, even in this remarkable case, there was no unusual variety observable in the nature of the murmur. Thirdly, in the case where, as I mentioned, there was a very small and impoverished placenta, Mr. Robinson and I detected a loud and lengthened murmur.

Having thus far endeavoured, for the sake of truth, to combat the ingenious theory of Dr. Kennedy, Ollivry, and others, I feel that I cannot, with propriety, decline offering some observations respecting my own opinion about the *site* of the murmur; this I shall venture to do, and shall take it as a particular favour, if I am in error, that my mistake should be rectified by some more experienced and more intelligent member of the profession. In the opinion which I am induced to adopt, I have many to agree with me; and I own it is to me both flattering and encouraging to find, that my

view fully coincides with that of a highly respectable fellow of the King and Queen's College of Physicians in Ireland, my very talented and very estimable friend Dr. Clinton.

[We defer to a subsequent Number the remainder of Dr. Nagle's observations.—*Ed. L.*]

#### SPONTANEOUS EVOLUTION.

##### *To the Editor of THE LANCET.*

SIR,—I entreat Mr. Cooper to believe that I disclaim every-thing resembling a doubt of his veracity, or disapprobation of his treatment of the cases recorded in a late number of *THE LANCET*. In my observations on his cases, I purpose nothing more than to suggest the necessity of the utmost caution in following his example, under peculiar circumstances. With the exception of Drs. Kelly and Denman, it has been admitted by all writers on the species of labour incorrectly described as "spontaneous evolution," that the popular notion of the arm's retrocession, and the conversion of the case into a breech presentation, is erroneous. Of the first-named gentleman it is necessary to remark that his belief is merely an opinion, apparently unsupported by the actual observation of such cases. Dr. Denman thought the arm ascended into the uterus; and I believe Mr. Burns of Glasgow held the same opinion. This misapprehension was first corrected in this country by Dr. Douglass of Dublin, who had been preceded in the relation of one case by Herder of Weimar. Professor Boer of Vienna gives an account of one in which the arm receded, but he was not certain that it returned into the uterus: in this instance Dr. Gooch believed that the position was not of the kind supposed, but that it was a breech presentation with the accidental descent of the hand into the vagina—an opinion which is strengthened by the circumstance of Boer not having felt the side of the child previous to the descent of the breech. It is stated by Professors D. Davis, Drs. Gooch, Douglass, and Herder, and confirmed by other practitioners (among whom I offer my humble testimony of two examples), that the arm is protruded from the shoulder; the side of the thorax is presenting and is protruded through the os externum before the breech, which, with the lower extremities, follow, and which are followed by, the head and the remaining arm. Dr. Douglass also mentions that although the descent is laterally until the nates arrive, "there is a twist made about the centre of the curve at the lumbar vertebræ, when

both buttocks, instead of the side of one of them, are thrown against the perineum, and immediately after, the breech issues forth, the upper and back part of it appearing first, as if the back of the child had originally formed the convex, and its belly the concave, sides of the curve."

Mr. Cooper's cases are most remarkable exceptions to what, on all the testimony we are at present possessed of, is certainly the general rule; and with the greatest respect and diffidence I suggest the inquiry whether he might not have witnessed parallels to Boer's case? If from irritation, fever, and all the other first consequences of great excitement, accompanied by rigidity of the parts concerned in the process, the patient be suffering, then Mr. Cooper's would be the indispensable remedies: indeed they are not only indicated in such cases, but ought oftener to precede protracted obstetric operations, especially turning, than they do. But it may be worth while to inquire how often, even with the advantage of this treatment, it may be good, in cases where the supposed evolution is expected, to consign the patient to the result of time, and the efforts of nature. When the child is small, the pelvis capacious, the mother in good health, and has previously borne children, efficient pains may be relied on, and the majority of such cases will terminate favourably without the interference of art, and with only the loss of the child. Not so, however, when the contrary of one, or all, of these conditions be found.

At the time that this variety of difficult parturition attracted the attention of the profession, instrumental midwifery had not received those valuable accessions which it since has, especially at the hands of Dr. D. Davis: at that time the, mis-called, spontaneous evolution was looked for as the most desirable event; and instrumental intervention was regarded as an evil of greater magnitude. With our present improved means of relieving such cases, I presume to think that the instances in which the termination by the supposed evolution will be preferred, are exceedingly few. It should be remembered that the children are already dead, or their loss is inevitable, and that when all hope of changing the position is lost, the next best thing to be done, is to complete the process as speedily as may be consistent with safety to the soft parts of the mother. The certainty of the ultimate ability of Nature to complete the delivery is not a sufficient reason for confiding in her; in very few cases would she be absolutely incompetent to the performance of the task; but it is well known that many may be more safely relieved by art than intrusted to her resources. Such do I conceive are a large proportion of the cases described as terminat-

ing by spontaneous evolution. When they occur at the full period of gestation, and all endeavours to alter the position are fruitless, what are the certain evils and probable risks to be incurred previously to the birth of the child? First, its death; secondly, very considerable, and often injurious, pressure on the contents of the pelvic cavity; thirdly, great diminution and derangement of the vital powers, and the probability of their ulterior disturbance, if not their entire exhaustion. What is a more obvious mode, or a better, of averting these consequences, than delivering the child, which may be done by separating the head, when easily accessible (which it is not always equally); or by perforating the presenting part, and (if necessary in consequence of inordinate bulk, eviscerating) fixing a crotchet on the spinal column, and then extracting it with the same caution which is required in forceps operations?

In offering these opinions I earnestly deprecate any imputation of advocating unnecessary and mutilating manipulations, and hope that should they be commented on by any of your correspondents, they will do me the favour to bear this disclaimer in mind, and thus supersede the necessity for my vindication being sought else than a justification.

I am, Sir,

Your faithful servant,

WILLIAM AUGUSTUS WALFORD.

\* \* Since the above communication I have, through the kindness of Mr. Dore, an experienced surgeon of Marchmont Street, had an opportunity of witnessing a novel variety of labour, usually and incorrectly denominated spontaneous evolution. I record it, not so much that it is in itself highly interesting, but rather that it is an additional disproof of the fallacy, that when shoulder presentations do not admit of turning, they frequently terminate by a spontaneous evolution of the child, and the case becomes converted into one of breech or foot presentation.

When I saw the patient, she had been in labour some hours; the os uteri was fully dilated, the liquor amnii discharged, and the uterus strongly contracting round the body of the child, whose arm protruded from the shoulder, while the right side of the thorax engaged with the superior aperture of the pelvis. As she had borne several children, had a capacious pelvis, was tolerably well in health, and had just entered the eighth month of her pregnancy, it was deemed expedient to trust the labour to the efforts of nature; the event justified the treatment, for the process was completed within a very short time. I did not witness its termination, but I am indebted to the politeness of Mr. Dore for the following de-

scription:—"The arm did not recede; the right side of the thorax came first, with the head doubled on the left side, and closely jammed against it; then followed the breech and inferior extremities." This case affords another proof of the incorrectness of Dr. Denman's doctrine of spontaneous evolution; and also of Dr. Kelly's error in asserting the resiliency of the child's arm at the termination of a pain; for during the short and ineffectual attempt which I made to turn, which was rendered fruitless by the frequent recurrence of the pains, I carefully noticed, that the positive position of the child was not altered on their subsidence.

The occurrence of this case at the present juncture, occasions a curious speculation in my mind, as to the influence of the "crown-er's quest law" on obstetric operations. We have lately heard the most atrocious slaughter described by a non-medical coroner as a mere mishap; and still more recently have seen a verdict, complimenting the perpetration of unnecessary and murderous dismemberment: under these circumstances it is a very natural inquiry, What would be the direction of a non-medical coroner, when the unavoidable loss of foetal life became the subject of inquiry? I shall be glad to learn from the advocates of the existing system, how a non-medical coroner could superintend an investigation where the operation of craniotomy or embryotomy had been the indispensable condition of preserving the more valuable life of the mother?

W. A. W.

#### THE LATE DR. NUTTALL.

*To the Editor of THE LANCET.*

SIR,—Having seen a letter published in THE LANCET, stating the distress of the widow and family of the late Dr. Nuttall, I herewith beg to enclose you one pound; ten shillings of which is from myself, the remainder subscribed by Messrs. Jeffery and Smyth, my pupils. The case, indeed, is a deplorable one, and I am sure cannot fail of exciting the sympathy of the profession; and depend upon it my utmost exertions will be used among my friends and patients for the relief of the unfortunate survivors. Believe me to remain, Sir,

Yours, very sincerely,

T. A. STOCKER.

Sidmouth, Dec. 8, 1830.

## THE LANCET.

London, Saturday, December 18, 1830.

HIS Royal Highness the Duke of SUSSEX made his first appearance in the chair of the Royal Society on Thursday evening last, and it must be confessed that the royal personage presented a very prominent figure. He was splendidly attired in a full court dress, and, in the absence of brilliant scientific attainments, was decorated with a profusion of brilliant stars. On taking the chair, his Royal Highness thanked the Fellows "for the honour they had conferred upon him, by electing him their president; and assured them, that he should constantly use his best endeavours, not only to advance the interests of science and of the Society (distinct things, certainly), but also of every individual Fellow. His *house* (he stated) was at present undergoing repair, but as soon as it was in order, it was his intention to throw it open, alternately on the forenoons and evenings of Wednesdays, for the reception of the Fellows, and also of men of science. This, he trusted, would suit the convenience of the whole of them; for those who could not do him the honour of breakfasting with him, might be able to attend from half-past eight until eleven at night. If he failed in any particular, he hoped they would not attribute it to a want of zeal in the cause. They would remember that he was young in office. He hoped, however, with the assistance of the Council, to give them general satisfaction."—The fellows appeared highly to relish this promising indication of the Royal Duke's substantial merits. His supporters are evidently not deceived in their man, and we give the Duke every credit for his own shrewd discrimination. The Duke, it appears, well understands the wants and tastes of those who so strenuously advocated his cause at the late election. His Royal

Highness is evidently of our opinion concerning the Society's *abdominal* condition, and, accordingly, means to support whatever there is left of a *head*, by devoting his special attention to the intestines. The Duke, whom we really believe to be a very worthy man, submitted (out of compliment we presume, to those members of the company of "shavers" to whom he was partly indebted for his new dignity), on the morning of the day on which he first attended, to the removal of the sable ornament of his upper lip; in a word, his mustaches had yielded to the unrelenting edge of the razor,—but we understand that, on *this* occasion, Mr. PETTIGREW did not operate.

His Royal Highness, on taking the Chair, did not seem very much at ease. In truth, from his manner one would suppose that in obtaining his present anchorage he had experienced a somewhat perplexing voyage. At all events, it is possible that the contemplated chance of a wreck had disturbed the serenity of his mind, for on admitting a gentleman as a fellow, he congratulated him on his introduction to the "Nautical" \* Society.

THE following is a correspondent's corrected list of the Gentlemen who openly supported Mr. Herschel at the late election.

THERE stands before us a pile of letters, all couched in terms of indignation and abhorrence, on the subject of the operation\* performed the other day at St. Bartholomew's by Mr. HENRY EARLE. Many correspondents, who neither sign their names, nor give us any means of knowing who they are, demand that we should insert their communications. Upon what grounds do they require that *we* should incur a responsibility from which they themselves are the first to shrink? It must be recollected, that, on another occasion, the publication of the TRUTH, cost us nearly ONE THOUSAND POUNDS. But, faithful in the discharge of our duty to the public, we have *again* published the truth,—that is, an unimpeachable report of what we deemed to have been a ———, no! there is no choice of adjectives here; ——— operation. Mr. EARLE certainly deserves no lenity at our hands, and after the dimensions to which he was reduced in the “overtures” and “professions” affair, in November, 1829, he cannot be a person towards whom one

is disposed to entertain even feelings of resentment. He is too small an object to be retained upon the tablet of the memory. The details of the operation are so painfully impressive and characteristic, that a commentary upon their peculiarities could only weaken the effect which a mere perusal of them must and ought to produce, upon the mind of every sensible and humane person. But we may venture to inquire, *en passant*, whether, if Mr. EARLE had performed such an operation in the private residence of either of the governors, he would ever be permitted to operate there again; and if not, upon what principle is Mr. EARLE retained in his office in the hospital? The mal-administration of the affairs of these institutions has become an evil of vast magnitude, and an effectual reform cannot, we fear, be wholly obtained through the pages of a medical journal.

We cannot dismiss this subject without calling the attention of the profession to the inquest which was held upon the body of the unfortunate child. It was thus briefly reported in *The Morning Chronicle* of the 8th inst. :—

“FATAL CONJURING TRICK.—An inquest was held yesterday at St. Bartholomew's Hospital, on the body of THOMAS BRADY, aged seven years. It appeared that the deceased and some other boys at school, were ‘playing the conjuror,’ which they did by putting nails into their ears, and pretending to draw them out at the nose. A nail was at length forced into the deceased's ear, which penetrated through the drum, and lodged in the cavity. The nail was ultimately withdrawn at the hospital; but the boy became insensible, and expired on Monday, from inflammation on the brain.—Verdict, ‘*Accidental Death.*’”

Thus the attendance of HENRY EARLE himself was not required by the wise non-medical judge! When, O when, will the proceedings of this court be regulated by the sound and just principles of common sense? If JOHN LONG, the felon, had performed the operation instead of HENRY EARLE, what would have been the verdict of the jury, and what would have been said

\* Reported at page 380 of our last Number.

by the profession? Answer *that question*, reader.

AFTER the above notice was written, we received the following letter, which we readily insert, because the writer thinks that it contains some palliation of Mr. EARLE's conduct. No other communication in his favour has reached us.

*To the Editor of THE LANCET.*

SIR,—I have just read in the last Number of your valuable Journal a very *partial* account\* of an operation for extracting a nail from a boy's ear, followed by a case of strangulated rupture, with some remarks made by Mr. EARLE. In common justice to that gentleman, who at all times evinces so much candour and openness in his conduct towards the pupils, and so much zeal to promote their interests and the cause of truth, I think it right to state, that after the operation Mr. EARLE expressed himself, as nearly as I can recollect, in these words:—"I regret that I have persevered so long in this case, as I am now persuaded that what I took for a foreign body, and which afforded so much resistance, was a portion of bare bone denuded by the repeated attempts to extract the nail, and the suppuration which followed. The head of the nail, which I did extract in fragments, was situated under this projecting portion of bare bone. On introducing my finger at the opening made by Mr. VINCENT, I distinctly felt that the floor of the meatus was destroyed, and thought that I could trace the head and body of the nail, which felt to me curved; but in this I must have been deceived by the denuded state of the bone, which conveyed the impression of a hard foreign body. Having removed the head of the nail, I was induced to persevere, which I now much regret." This, Sir, was the candid acknowledgment of Mr. EARLE. Compare this with the attempt of Mr. ——— to deceive the pupils and hide his failure, by telling them "there was an hour-glass contraction of the bladder" (vide his case of lithotomy). It is right to remark, that many attempts had been made before Mr. EARLE saw the case, who was only consulted because *symptoms of affection of the brain had commenced*. With respect to the case of rupture, your reporter has omitted to mention that Mr. EARLE expressly stated he took that opportunity of impressing on the minds of those present the danger of delay. He said he was aware he had expressed himself strongly, but after witnessing such consequences he could not but feel strongly, and it was for

the benefit of those present that he urged the danger and impropriety of delay.

I trust you will admit these few lines, in justice to a gentleman who, if he has been severely just in commenting on the conduct of another, has shown no wish to favour himself when in error. Yours,

A LOVER OF CANDOUR.

Dec. 16.

*Ecce iterum, crispinus!*—WILLIAM BAKER, Coroner! The following report of an inquest which was held under the Presidency of this very learned attorney, was published in *The Times* of Wednesday se'nnight.

"Yesterday an inquest was held before Mr. BAKER, at the London Hospital, on the body of MARTIN MERTINS, an infant of 14 months of age, on suspicion of occasioning whose death by wilful burning, ELIZABETH SMITH, his late nurse, is now in custody. The facts stated yesterday in *The Times*, in the report for Worship-street, were proved at length." (On turning to the account here referred to, we found the following statements.) "Yesterday, Elizabeth Smith, about 17 years of age, was charged before Mr. Broughton, at Worship-street Police-office, with the following unparalleled cruelty to an infant, which has occasioned its death:—Ann Mertin, the mother of the infant, stated that she resided in Quaker-street, Spitalfields. She kept the prisoner to nurse her child, who was 14 months old, as she had occasion to go out to work. On Thursday morning last she went out as usual, about 8 o'clock, to her work, leaving the prisoner in care of the infant. About 6 o'clock at night the prisoner came to her and said the child was ill, and requested she would come home; she hastened home, and found the prisoner's mother in care of the infant, and who said that her daughter had met with an accident with the child. Upon taking the infant in her arms, a most horrid spectacle presented itself,—the flesh was entirely burnt off the lower part of the back and belly, and the child in the most excruciating torture. She applied such things as she was recommended to use, but the next morning it got worse, and she took it to the London Hospital, where every attention was paid to it: she was also allowed to remain with it, and it lingered until Sunday, when it expired. The surgeons and nurses of the Hospital had expressed their opinion that the child had been made to sit upon the fire, as the clothes which were produced were not even scorched. It was a fine boy, and the only one witness ever reared out of five.

\* Our report was strictly accurate.—ED. L.

The poor woman was dreadfully affected during the above narration. The prisoner in her defence said, that the child awoke about half-past 4, and she took it out of bed immediately, and held it over the ashes with its clothes up, for an occasional purpose: there was a very large fire, which blistered the flesh, when the child began to scream, and she instantly took it away: finding what had happened, she took the child to her mother's.—Mr. Broughton said, that the fire must also have blistered the prisoner's hand; he had no doubt but the child was put on the fire as a punishment for what it had done in the bed. He should remand the prisoner till Friday, to await the result of the coroner's inquest." After the above facts had been proved, "the Coroner addressed the jury, observing, that from the whole of the evidence, it appeared to him that the nurse, ELIZABETH SMITH, had, either to deter the infant from again committing some fault, or to punish it for having so done, held it to the fire, and unfortunately so long that it had received a fatal injury, but that he could not believe the girl intended to seriously injure or destroy it. That, therefore, if the jury coincided with him, they would not deem themselves justified in returning a verdict of murder or manslaughter, but one of accidental death, with some censure on the prisoner. The Jury accordingly returned a verdict of 'Accidental death, through the culpable neglect of ELIZABETH SMITH, but whose conduct does not amount to an act of criminality.'

At the late county contest, the imputation of deficiency in legal knowledge was repeatedly cast in the teeth of the advocates of a medical coroner. At the same time, it was admitted that the medical candidate had proved himself to be not altogether deficient in legal information; but in the way of comment on the alleged fitness of medical men generally for the office, there was the unceasing jeer of,—“Yes; but a man cannot be qualified unless he have a knowledge of law.” From motives which it is unnecessary to explain, we have refrained from criticising the manner in which Mr. BAKER has hitherto discharged the *legal* duties of his office, though, we must confess, that the occasions have many times been almost too tempting to be resisted. A coroner like this, may, we hope, be looked upon as a medico-legal curiosity; a fit animal for a niche in a museum, or a cage in

a menagerie. Mr. BAKER, to be sure, furnished evidence enough at the election that he was entirely innocent of being possessed of any very considerable acquaintance with the laws of his country; but, unhappily, from the position in which he is now placed, his extreme ignorance of that branch of the law which relates to the duties of coroner, is likely to have a baneful effect upon the interests of the inhabitants residing in the eastern district of the county. It is really lamentable to reflect, that an office of such vast importance, is thus, through the ignorance of its presiding officer, converted into an instrument calculated for no other purpose, than to extract money from the pockets of the freeholders and other inhabitants of MIDDLESEX. If the report which we have taken from *The Times* be correct, and of its accuracy we are assured by a gentleman who happened to be present at the inquest, Mr. BAKER is altogether ignorant of what constitutes the crime of manslaughter in the eye of the law, and we must take upon ourselves the arduous and unprofitable duty of lecturing him into some small degree of legal information,—a task which we, certainly should not have undertaken, if the work of Mr. JERVIS on the duty of coroners were not at hand to support our opinions by the weight of its authority. Satisfied, then, of the accuracy of the report, we hesitate not to inform Mr. BAKER that ELIZABETH SMITH was guilty of manslaughter, at least; and the question,—Was she not guilty of murder?—is one that would certainly be answered in the affirmative, by, we think, many able lawyers of the day.

The distinction between murder and manslaughter is this: that in the former crime there is malice; in the latter, none; but a cruel wench, who could expose an unhappy child's *nates* to the scorching effects of red-hot coals, until blisters had been raised upon the skin,\* in spite of its struggles and its

\* The gentleman before alluded to, who was present at the inquest, has stated to us that the poor little infant's *scrotum* was swollen as big as his fist, and that the parts were most horribly scorched.

cries, can scarcely be said to have acted without malice. At all events we should ourselves have held no such doctrine. If, however, the crime did not amount to murder, it was, beyond all question, a case of manslaughter, and one, too, which required that a very severe punishment should be visited on the perpetrator. If the girl scorched the child in the way of correction, even with *good* intention, it was manslaughter. This, of course, is too astounding a statement to obtain the assent of Mr. BAKER, if it be allowed to rest upon our individual *medical* authority. We shall therefore treat him to an extract from JERVIS—an authority which he will do well to consult upon all inquests of the least importance.

"If killing be done with a *dangerous* weapon likely to endanger life, or cause bodily harm, due regard being had to the strength and *age* of the party, it will be *murder*; but if with an instrument not likely to cause death, though improper for correction, it will amount to *manslaughter* only. Yet where the act is manifestly intended for a *good* purpose, and the instrument used is not such as in all probability must occasion death, due weight should be given to the nature of the provocation, even though the party be hurried to great excess. Where a father, whose son had been frequently guilty of stealing, and, complaints having been made, had often been corrected by him for it, beat his son in the heat of passion with a rope by way of chastisement for another theft with which he was charged but resolutely denied, although it was proved against him, and the son died, upon which the father expressed great horror, and was in the deepest affliction for what he had done, intending only to have punished him with such severity as to have cured him of his wickedness; it was holden to be *manslaughter only*."—*Jervis on the Office and Duty of Coroner*. 1829. p. 157.

Mr. BAKER will do well to store up these words in his memory, even if he possess not those ideas by which alone he can estimate their true value. The *literati* will soon be called upon to decide whether it be chiefly from ignorance of law, or of medicine, that attorney-coroners are most unqualified to preside at inquests.

THE following letter on the subject of the alleged improper dismissal of patients from St. Bartholomew's Hospital has been addressed to us by Mr. Wood, the house surgeon:—

To the Editor of THE LANCET.

SIR,—I beg leave to offer you a correct statement of the circumstances connected with the departure from St. Bartholomew's Hospital of the poor unfriended man, whose injuries you so deeply commiserate in this day's number of your Journal. This patient, whose name was Hugh Fletcher, came into the hospital on the 4th of November, with a chancre on the prepuce and a large sloughing hubb in the groin. The marked and rapid improvements of the symptoms, under the employment of simple means, induced the surgeon to point out the case to his pupils, as one of particular interest. There could be no question about the propriety of keeping such a patient in bed, but this confinement displeased him. I told the man, after having repeatedly found him up, that, if he would not remain in bed, he had better walk off. He departed accordingly, and the surgeon was surprised to find him absent when he made the visit the next day. So then it is true, that "on the Sunday he had been directed by the house-surgeon, Mr. —, to keep in bed;" but it is not true that "on the Monday he was deemed by the visiting surgeon a fit subject for the streets."

Now, Sir, as far as this hospital is concerned, I shall venture to add my dissent to the whole of the paragraph from which the above sentences are extracted. The medical directors, far from "often sending out at a few hours notice poor creatures, who have been for weeks bedridden and subjected to long courses of mercury," on the contrary, I say it with pleasure, often show great indulgence in this respect.

Your extra-professional readers may perhaps not all be aware that two classes of sufferers receive the benefits of this institution; the more seriously afflicted within doors, the less afflicted without. Ignorant patients often entertain the notion, that, when they once become inmates, they ought, before their discharge, to be completely cured of their maladies, supposing them to admit of a cure. But, were such a notion suffered to be carried into effect, the benefits of these charities would be considerably diminished, and the mortality of our metropolis greatly enlarged. That convalescents, who can attend as out-door patients, should give up their beds to persons who are labouring

under greater suffering and danger than themselves, can only be objected to by those who are too selfish to carry their views beyond their own immediate interest.

I shall be obliged to you to permit this letter to be inserted in your Journal; but, before concluding it, let me express the hope that you will be more careful in future of soiling its valuable pages by imputing cruelties to a body of men truly humane and respectable, and that you will not so readily shake off your wonted scepticism to give implicit confidence to the complaint of a gang of vagabonds and ingrates, who are branded with a disease, which to its many loathsome qualities is well known frequently to add one, the most disgusting of all,—that of making its professors conceal and pervert truth.

I remain, Sir,  
Your obedient servant,  
JOHN WOOD.

House Surgeon's Apartments,  
St. Bartholomew's Hospital,  
December 11, 1830.

Mr. Wood doubtless considers that the foregoing letter contains an ample refutation of the statement which we made last week concerning the improper dismissal of the patients. We cannot enjoy the satisfaction of agreeing with him in opinion. Mr. Wood acknowledges having said to the man, that he had better "walk off" if he could not keep in bed. Now the case was one of sloughing bubo, and the patient, probably, derived some benefit from taking an occasional turn in the ward. This might have been in opposition to Mr. Wood's notions of the action of the curative process, but we certainly think that the house-surgeon went too far in telling the man that he had better "walk off" for so slight a deviation from his orders. Besides, Mr. Wood would not have said as much to one of the surgeon's patients in private practice, and this should always be the rule of conduct for hospital functionaries. Let the inmates of our public medical charities be treated with the same degree of kindness as persons of the highest station, who may be visited in their own houses. The want of veracity met with in venereal patients, is a new fact which future pathologists will be grateful to the surgeons

of St. Bartholomew's, for their having been the first to notice. Mr. Wood is somewhat displeased, and calls his patients a "set of vagabonds and ingrates." If they be such a set of vagabonds, why are they deemed proper objects of charity and admitted into the hospital? The house-surgeon, probably, is not aware, that before patients are received into the institution, they obtain a petition from the steward, which is ultimately signed by a governor, representing that the petitioner is a proper object of charity, and the propriety of admitting him into the hospital, is then left to the discretion of the surgeon. When patients have been received under such circumstances, it is going rather too far to designate them as "a set of worthless vagabonds." Again, does not Mr. Wood know that this rule of petitioning is a mere matter of form? That the governors are only trustees? That the funds of the hospital are really the property of the poor, and that the surgeon is, *ipso facto*, the servant of the poor patients? That the trustees are not uncontrollable, and that the discretion of the surgeon is not checked only because the soundness of his judgment is not questioned? The surgeons ought to know, that a poor person labouring under distress and dangerous disease, can at any time procure an order for admission from the hands of the Lord Mayor; an order which, under pressing circumstances, his lordship would withhold at his peril. In a word, the hospital belongs to the diseased poor, and not to the medical officers who pocket such enormous fees for frowning at them two or three times a week.

Upon inquiring of one of the patients who paid us a visit, the reason of his unceremonious discharge, he answered, with peculiar *naïveté*, "Why, Sir, you see, God bless 'e, the surgeons have got a tur'ble number of them 'ere gentlemen pupils, who pays 'em so much a-head to see our wounds dressed, and to see us cut about; and when

we wants no more cutting and be getting a little better, we be turned out to make room for fresh ones, because, Sir, you know, the pupils won't pay if the doctors don't show 'em some work. Only t'other day, right afore us in the ward, I seed a gentleman pupil pay the doctor six or seven and twenty pounds. Bless 'e, Sir, the nurses says as how the doctors gets thousands and thousands in that 'ere way, and sartently the gentlemen pupils won't pay that 'ere money if they get *nothing* for it. Bad work's better nor none a' tall."

Shrewd as was this man, *he* evidently knew *nothing* of Lincoln's Inn Field politics.

In dismissing this subject for the present, we must express a firm hope that those patients who may be received into the hospital as fit objects of charity, will not, in future, be dismissed without a proper timely notice.

In making our observations, we have had no second purpose to serve, certainly no desire to detract from the merits of Mr. Wood, whom we believe to be zealous in the discharge of his duties; but, hospital physicians and surgeons should ever remember, that medical science ceases to be of value if it be not blended with feelings of considerate benevolence.

#### DIABETES IN HORSES.

In a late Number of the *Journal de Chimie*, M. Lassaigne gives an account of a disease in horses, which has, for the last three months, been frequently observed by the veterinary surgeons of Paris; its principal character appears to be, the evacuation of a very large quantity of urine, which sometimes amounts to about six litres per hour. The urine, having been examined by M. Lassaigne, was found to be clear, of straw-yellow colour, and very little smell; it reddened litmus paper, though but feebly, and not before some time, and consisted of

Water.....	98,0
Urea, benzoate of potash, acetate of potash, acetate of lime, chloride of soda, and free acetic acid	1,5
Mucus.....	1,5

It accordingly differs from urine of healthy horses—first, by its great quantity of water; second, the presence of free acetic acid; and third, the entire absence of carbonates. No trace of saccharine matter could be discovered in it.

#### DISCOVERY OF NERVES OF THE CORNEA.

We find it stated in a German journal, that these nerves have been lately discovered by Professor Schlemm of Berlin, according to whom they originate from the superficial branches of the ciliar nerves, and may be traced along the sclerotic, and over the orbiculus ciliaris towards the cornea, between which and the sclerotic they penetrate, and become imperceptible.

#### WESTMINSTER MEDICAL SOCIETY.

Saturday, December 4, 1830.

Dr. STEWART in the Chair.

#### PATHOLOGY OF FEVER.

Dr. SIGMOND rose and commenced by observing, that in compliance with the wishes of the Committee, he had selected the pathology of fever, as the subject to which he should call the attention of the Society, one which, at any rate, could not fail to excite an interesting discussion.

The nature of fever, from the earliest periods of medical science, has been the subject of much investigation; valuable have been the observations which have been handed down to us, and a multitude of the most intelligent men that society contains, were daily and hourly increasing our stock of information; still, it should be candidly confessed, that however perfect our treatment of fever has become by practice and observation, there is much wanting to explain satisfactorily the train of phenomena that arise. The two leading characteristics of fever, are generally acknowledged to be, an unusual state of animal heat, and an alteration in the action of circulation; and to this is added, a great depression of the sensorial powers. The first is indicated by the state of pulse, the second by the sensation of heat. The question naturally arises, What causes produce these changes? With regard to heat, the lungs, by their inhalation of oxygen, generate caloric, which remains latent until it is distributed over the body by the circulation of the blood, but this evolution seems materially to depend upon the brain, the medulla

spinalis, and the nervous ganglia, whose healthy action, as in other parts of the system, materially depends upon the equable circulation of the blood; the state of the pulse is affected by the undue action of the heart and arteries. Whatever accelerates the circulation of the blood to the brain, causes a greater degree of distribution of caloric, and produces excitement; thus stimuli, either mental or bodily, impart energy to the nervous system, and increase the heat,—whilst that which retards the circulation depresses mental power, and chills the frame. Wine, as long as arterial acceleration goes forward, adds to the sensorial power, and imparts heat to the body; but when venous retardation takes place, the mind suffers, and cold is also produced. Intermittent fever, Dr. Sigmond considered, to depend upon an alternate collapse and excitement of the brain, the circulation not imparting to the brain its healthy stimulus. There was diminished influence of the nervous system over the whole body, the result of which is the cold stage,—heat, not given out to the surface of the body, is accumulated in the internal parts, until a re-action is produced by the energy acquired by the nervous system, an excitement which determines the accumulated heat to the surface of the body,—these alternate actions and re-actions give rise to the phenomena of intermittent fever, which are too well known to need description. The periodical recurrence of the paroxysm, is attributable to the same general law of the animal economy, namely, that organs perform at stated periods their functions, whether healthy or morbid, such as the uterus unloading itself at its peculiar period, the stomach performing its digestion at a certain time, and on definite days, the eruptions go through their course in exanthematous fevers. Neither the humoral pathology, nor the doctrine of the lensor of the blood, nor spasm of the extreme vessels, nor the doctrine of excitability accumulated and exhausted, nor inflamed brain, is admitted, though the ingenuity and talent which Hippocrates, Boerhaave, Cullen, Brown, and Clutterbuck, are universally acknowledged, nor have they explained satisfactorily to us that which we daily see. The system which appeared to be the best, was that which viewed the connexion between the brain and the vital fluid as so intimately, so closely associated one with the other, as to produce energy or debility as they act upon the other. Deficient energy of the brain extending its influence over the whole body, is an evident law of the disease; and the stimulus which the sanguiferous system gives to the brain, seems essential to restore that diminished sensorial power.

The observations of M. Bailly have esta-

blished too, as a fact, that the mean duration of intermittent fevers in all climates is precisely the same, namely, fourteen days, and this corresponds with most acute diseases which seem to have a remarkable tendency to run their course in that time; where intermittent fever appears present after that period, it consists but of a nervous periodical affection, which is the result of the morbid susceptibility contracted, but which has not the essential characteristics of the disease.

Continued fevers are inflammatory and nervous. In the inflammatory disease determination of arterial blood to the brain and nervous system cause increased heat, the quick and full pulse. In the nervous or typhoid disease, the retardation of blood takes place, the brain loses its natural stimulus, and there is a deficiency of heat; the heart has not power to throw off the blood which is accumulated within it, a venous congestion is the consequence. The mere unloading the veins is then not sufficient, energy must be imparted to the nervous system, and upon this the restoration to health depends. Whatever then destroys the equilibrium of the circulation, impairs the nervous energy, and as nervous power is necessary for the due action of circulation, these two functions act and react upon each other, producing the symptoms which form fever. Upon this reasoning depends our plan of treatment; in inflammatory fever we diminish arterial action, and prevent its influence on the brain and nerves; in typhoid fever we increase the powers of the brain and nervous system by stimuli, and thus excite the healthy circulation.

Dr. BARRY said, that while Dr. Sigmond had deemed it necessary to enumerate all the fathers of medicine in his views of the rival theories of fever, it appeared extremely strange that the name of Broussais was entirely neglected; Broussais, whose peculiar doctrines were at the same time of such interest and notoriety, that to pass them over, reminded him of the performance of Hamlet, in which the part of the Prince of Denmark was omitted by desire. The same remark, he considered, would nearly apply to Dr. Sigmond's silence on the anatomical features of the disease. As to alteration of heat constituting one of the peculiarities of fever, he (Dr. Barry) thought Dr. Sigmond was wrong in not stating, that this alteration should be *above* the natural standard; alterations *below* this do not constitute fever.

Dr. SIGMOND replied with great good humour to Dr. Barry's principal objections. He recapitulated some of his opinions, and in allusion to the cause of intermittent, spoke of the analogous effects which, in his own experiments, he had known to be produced by the smelling of sulphuretted hy-

drogen, by which all the phenomena of a paroxysm of intermittent could be produced. He did not agree with Broussais' opinions.

Mr. KING believed, that many different diseases were confounded under the term fever; he scarcely knew any affection which might not be included under the ordinary definition applied to this disease. He would not call every affection fever in which there were increased heat, pain, and accelerated pulse, but he would confine it to instances of these phenomena occurring, without any organ or set of organs being determinately affected.

Dr. A. THOMPSON passed a warm eulogium on Dr. Southwood Smith's treatise on fever, he agreed fully with the circle of morbid actions pointed out by that author.

Dr. BARRY apologised for standing up so often, but the observations just made involved matters of the most serious moment. In the first place, though he had a high respect for Dr. Smith's talents, and considered his book a perfect specimen of fine professional writing, yet he could not pin his faith upon the one, or set up the other as the Alcoran of fever practice.

Mr. CHINNOCK declared himself a warm disciple of Broussais, he had never known a fatal case of fever in which, on examination, the abdominal appearances, contended for by that author, were not detected. He might add, that exposure to vegetable malaris, he believed, usually induced an inflammatory affection of the brain or spinal chord; cases of this kind had indeed fallen under his own observation.

Dr. BLICKE said, that with respect to the dependence of intermittent on malaria, he was in possession of rather a curious fact,—he described minutely the topography of a small island in the north sea (the name we could not hear), on which there was not a single tree or any vegetation more than a thin sward; it was twenty miles from land, and yet its inhabitants were frequently attacked with intermittent fever.

The PRESIDENT inquired, whether the peculiar smell noticed by Dr. Smith, could be corroborated by any of the members present. Dr. Sigmond replied, that it existed also in erysipelas. Dr. Barry mentioned an extraordinary circumstance, for the truth of which he pledged himself, that he knew an individual who could recognise the yellow fever by its smell, as exactly as a dog could scent a partridge. (*A laugh.*) It was a fact; he had known him enter a street, stop before a house, and say the yellow fever was in it, guided by his sense of smell alone. (*Renewed laughter.*)

Dr. ADDISON opposed the doctrines of Broussais on the data of his own necrotomic examinations. In the most decided fevers,

he had frequently ascertained the absence of the slightest gastro-enteric inflammation, while, on the contrary, he had examined bodies of persons totally free from fever, in which the abdominal mucous membranes were extensively engaged.

Dr. SIGMOND again replied, and the discussion was, on the motion of Dr. Granville adjourned to the following meeting.

*Saturday, December 11, 1830.*

Mr. CHINNOCK in the Chair.

Mr. JEWEL related an extraordinary instance of unusual weight of the human fœtus at the full time. The case was communicated to him by an extremely intelligent midwife, of whose veracity no doubt could be entertained. It was the mother's fourth child, the several previous labours having been greatly protracted, and all the children still-born; on the present occasion, the midwife being desirous to save the child's life, administered the ergot of rye in large doses, thirty hours after the liquor amnii had been discharged, and the head descended, but had been arrested in its progress; three hours after this the delivery was accomplished, and the child weighed 20lbs.!

The debate on fever was then resumed, and supported with much spirit and ability by Drs. Sigmond, Barry, Somerville, Wood, Stewart, and Mr. Gilbert Burnet. A paper on the pathology of dropsy, by Dr. Wood, was announced for the ensuing evening.

## ROYAL INSTITUTION.

EXAMINATION OF AN EGYPTIAN MUMMY  
BY DR. GRANVILLE.

ON Saturday, the 11th inst., Dr. Granville performed the examination of a mummy presented by Sir John Malcolm to the Asiatic Society. The operation was conducted in the large lecture-room, which was crowded by a large assemblage, amongst whom we observed Lord Grey, and many other eminent individuals. The mummy was placed in its loculum on the centre of the floor, till the arrival of Dr. Granville, when the chair was taken by the vice-president of the Royal Institution.

Dr. GRANVILLE prefaced his examination by some introductory and explanatory remarks, in the course of which he apologised for the unavoidable absence of the Duke of Sussex, who was expected to have presided on the occasion. He noticed at some length the scientific and laborious exertions of the Asiatic Society, to whose liberality the present opportunity was due, of examining another of those extraordinary remains of a

people whose existence was otherwise more traditional than established, remains which had escaped the ravages of decomposition for more than 3000 years. These investigations, he continued, were not a mere matter of idle or useless curiosity, but their results afforded, as it were, an epitome of the civil history of that singular people. They, at the same time, elucidated the religious doctrines, and showed the knowledge which the Egyptians possessed of the fine arts of mechanics, of surgery, and of chemical processes; they also proved the feelings of veneration with which that singular nation regarded their dead, and the skill with which they had devised means of transmitting in their own persons, to after ages, monuments as imperishable as the most solid structures of architectural art. This example Dr. Granville suggested might be acted on even now in this country, and he alluded to the projected necropolis of Messara. Goodman and Watt, drawings of which were exhibited to the assembly.

Dr. Granville then proceeded to the opening of the cases in which the mummy was deposited; they consisted of three loculi, the outer of which was excavated from a solid block of sycamore, the timber remaining in a state of the most perfect preservation, scarcely exhibiting a vestige of decay, or the action of worms, and looking almost as if it had issued from the carpenter's hands within the present year. Its upper surface was as usual painted and varnished, and the part corresponding to the head of the enclosed body was fashioned into a well-executed cast, supposed to resemble the head of the deceased, and ornamented with the dress and neck-lace peculiar to this people. The second case was composed of several longitudinal pieces of the same timber, painted and moulded at the head in the same manner, and fitting into the outer receptacle with great exactness but sufficient freedom. The carpentry of the entire was of the most complete kind, and the proportions admirably preserved. The third case was now arrived at; this was formed of five layers of cotton-cloth, cemented together with lime and an astringent matter, moulded to the form of the enclosed body, along the back of which it was divided in its full length, and laced in an interrupted suture by strings of the same material with the cloth, and which were perfectly elastic and free from decay. It appeared as if the layers of cloth had been applied to the body in the moist state, and the case thus allowed to accommodate itself to the required form, that the body was then submitted to the preservative process, and replaced through the longitudinal aperture, which was then finally secured.

The body was now extricated, shrouded in

a double series of cloth wrappers; the outer one was a general envelope, and beneath this was the second, consisting of several hundred feet of *roller*, by which the body was bandaged in a manner so skilful, as entirely to justify Dr. Granville's assertion, that the Egyptians were adepts in at least one important branch of surgical manipulation. The turnings were, indeed, beautifully suited to the form, and inequality of surface obviated by compresses applied with the most skilful nicety. The cloth was apparently of cotton, of an opimient yellow colour, *with a double blue border*, like an English rug, each thread being composed of two twists, and retaining its elasticity with great perfection. The colouring matter Dr. Granville stated to be tannin; and from some experiments we have instituted on a portion of the fabric, we have reason to believe his statement to be correct.

It was now found that the remains were preserved by the cheap or inferior process; namely, by an immersion in boiling pitch and asphaltum, which had also been injected, most probably by the anus, into the abdomen. The muscles were therefore either hardened or entirely obliterated in every situation.\* On further examination, it was ascertained, that the mummy was that of a male, five feet five inches in height. The skull was in a state of great preservation; externally it exhibited any-thing but an intellectual formation, the anterior regions being but imperfectly developed, while the posterior were large, and the organ of firmness protuberant, and expanded almost to deformity. The general conformation of the head, and several other osteological phenomena, concurred in determining the class of the remains to be the Caucasian and not the Ethiopian variety of the human race. On removing the skull-cap, the dura mater was found entire, its surface traversed with blood-injected vessels, as if it were anatomically prepared, its structure retaining its fibrous transparent character, and yielding easily to the knife. A section of the dura mater at one side having been performed, the falx and tentorium were seen in the same perfect and beautiful condition, *but not a vestige of arachnoid or brain remained*; on which extraordinary circumstance Dr. Granville commented at considerable length, particularly noticing the extreme ingenuity of any process by which the brain and arachnoid could be removed without at all injuring the dura mater or its projections. The diploë of the cranium was quite evident, and the marks of the vessels on its interior surface as distinct

\* A contemporary has talked of adipocere having been found in this specimen; we must, however, totally deny the accuracy of such a statement.

as in a subject just dead. The examination concluded here. During the dissection, Dr. Granville stated, that, in some cases, not only do the muscles remain perfectly flexible, but the internal organs are also in a state of preservation so complete, that the disease which terminated the individual's existence may be ascertained; the process of embalming is, however, different in these cases, and in particular, a considerable quantity of waxy matter is found in different situations.

---

#### OBSERVATIONS ON THE ACTION OF THE HEART.

I WAS truly surprised, in reading over THE LANCET for October the 2nd, to find a gentleman affirming as his opinion, that the cause or stimulus which excited the heart to action, functionally existed in the sympatheticus maximus; that, in fact, both the cause and effect are functionally existing in the same nerve. Now I will not hesitate to affirm, that this is contrary to everything in Nature's economy of organized life. The action itself, and the exciting cause of action, do not, I believe, exist together in any one structure. To excite sensation in a nerve, there must be an operating cause, not in the nerve, but *applied* in some way to the nerve. No nerve contains the sensation and the exciting cause of the sensation: the light is *applied* to the eye to excite its sensibility—sound to the ear—food to the nerves of taste, and so forth,—and to produce voluntary motion, there must be a cause, sensorial sensation (i.e. perception), and action (volition), which latter action is *applied* to, or sends its influence through the processes of the base of, the brain (the nerves which are conductors of it), to those muscles subservient to the sensorium, the voluntary muscles. Now just as there must be a stimulating cause for those above-mentioned sensations, and for the contraction of the voluntary muscles, viz. the application of the will to the nerves of those muscles, so there must be the same for the contraction of the heart and all other involuntary muscles,—bile for the alimentary canal (or some accidental exciting cause) for producing contraction of the heart. If it is true that in Mr. Dobson's experiment there was no blood for the heart to contract upon; but does he forget that the heart was still working in a very stimulating foreign fluid, the air—oxygen gas? In a vacuum, I believe, the action of the heart would very soon, but probably not immediately, have ceased. For I believe, that as sentient parts acquire a capability of containing sensation for a certain time after

the cause has been removed, which I would call the habit of sensation, so involuntary parts, I believe, acquire a habit of action which is not got rid of at once; and the immediate cause of this is the agency of the living principle of organic matter—life, whatever the proximate nature of that agent may be; it is a part of what I would term organic instinct. It is for this reason that we have seen an object after it has been removed from the eye, because the action of the retina has not yet ceased; and for the same reason the effect, or action, produced by the *habitual* stimulus of the blood had not, in this experiment, quite ceased. I believe that the sympatheticus maximus, by its ganglia, may bestow sensibility and action to the heart and involuntary viscera, different from that possessed and bestowed by the nerves of common sensation. This, together with uniting parts in sympathy, are the only uses which I conceive the ganglia have; they are not brains, for they have no *thinking* part or volition, like cerebri. Are they not analogous to the base of the brain, more particularly to the pons varolii, acting as a source of irritability to the heart, but not as an exciting cause, because without that cerebral or nervous substance which possesses thought and volition, the latter being the moving stimulus to voluntary muscles?

G. D. DERMOTT.

#### ABUSES AT ST. BARTHOLOMEW'S.

To the Editor of THE LANCET.

SIR,—As an old Bartholomew pupil, and having fresh in mind the "golden days" of Mr. Abernethy, and withal having the interest of my fellow-students at heart, I cannot resist writing to you, as the abhorrer of "hole-and-corner practices," concerning one of the many that now exist at St. Bartholomew's. I allude to Mr. Stanley's lectures,—and I feel quite sure that this gentleman, who has always *professed* himself so warmly on the subject of forwarding the interests of the pupils, will not take amiss a word or two of advice I now wish to give him; I allude more especially to the subjects he has this season selected for his lectures; and the unconscionable haste with which he has hurried over some of those which I remember were Mr. Abernethy's most favourite lectures. I may mention, as an example of this, the muscles of the lower extremity, begun and ended by Mr. Stanley in two lectures. Moreover, never surely were subjects brought into a lecture-room more ill-adapted for the purpose than those which have been exhibited in our theatre

this season—subjects so far advanced in a state of putrefaction, that the gentlemen sitting in the nearest rows have been precluded from seeing aught that the learned lecturer was demonstrating. This subject abandoned, we have a child of two years old exhibited, on which he is attempting, I need scarcely add fruitlessly, to exhibit the blood-vessels, and this to a class consisting of nearly 300. Did we pay less, and had we fewer promises, we perhaps might be induced to put up with such unworthy conduct. But paying the liberal sum we do, and with Mr. Stanley's warm professions, I feel sure you will agree with me in the reasonableness of the outcry raised against such conduct. I write this not unknown to many of my fellow pupils, and I, in common with them, shall indeed feel myself indebted should you either by inserting this letter, or by other means not less effectual, remedy so glaring an evil.

I remain, Sir, yours,

A LOVER OF JUSTICE.

#### DERBY INFIRMARY.

*To the Editor of THE LANCET.*

SIR,—YOUR LANCET of last week contains another of "Reporter's" false accusations against Dr. Baker; happily, however, for the persecuted and unjustly condemned, the governors view with disgust the motives that are well known to have prompted "Reporter" to put forth so false and malicious a charge against one of their officers.

"Their better souls abhor a liar's part;  
Wise are their voices, noble are their hearts."

Would I could say the same of this detestable calumniator.

As I hear that a gentleman is already engaged in answering this "Reporter's," or rather "impostor's" assertions, I shall desist from troubling you further.

I am, Sir, your obedient servant,

HENRY GISBORNE.

Green Lane, Derby, Dec. 13th, 1830.

\* \* We insert this note from Mr. Gisborne, but that gentleman himself must admit, that it does not refute a single statement which has been made by our respectable correspondent's "Reporter."—ED. L.

---

#### PRACTICAL RIGHTS OF PHYSICIANS AND APOTHECARIES.

*To the Editor of THE LANCET.*

SIR,—I have just received THE LANCET for the 20th, and therein I find that when speaking of the privileges of physicians,

you seem to differ with Mr. Willcock, who maintains that they possessed the power to prepare medicines according to their own prescriptions prior to the passing of the Apothecaries' Act; and moreover, that these privileges were granted them in the "saving rights" of that act. Now there is one question which I hope you will answer in your next Number. Can a physician prepare his own medicines out of London, that is, any-where in the country? For you say yourself, "In a word, neither a fellow of the London College of Physicians, nor a graduate of the University of Edinburgh, can follow the business of an apothecary avowedly as an apothecary in *this town*." By your merely mentioning "*this town*," therefore, it would appear that they can exercise the art of an apothecary any-where but there.

I remain, Sir,  
Your obedient servant,  
AN EARNEST INQUIRER.\*

\* \* Physicians did enjoy the right of preparing their own prescriptions before the Apothecaries' Act was passed, but that right was not preserved to them in the saving clause of the Act.—ED. L.

A physician cannot practise as an apothecary, either in or out of London, unless he be a licentiate of the Apothecaries' Company.—ED. L.

---

#### ST. BARTHOLOMEW'S HOSPITAL.

FUNGUS HEMATODES.—PROPRIETY OF OPERATING.

*Clinical Remarks.—Monday, Dec. 13th.*

MR. LAWRENCE,—The tumour which is here submitted to your observation, was taken from the thigh of a gentleman on Saturday last. The case possesses much interest, indeed I think I may say it is unique, for I have never either seen or heard of one similar in its results; and since the knowledge of the facts may prove useful to you in practice, I think it worth while to

---

\* An "earnest Inquirer!"—In our correspondent's extreme anxiety, he forgot to pay the postage of his letter, which amounted to one shilling and three-pence. It gives us pleasure, at all times, to afford to querists whatever information we may happen to possess respecting any subject on which they may be desirous of obtaining information, and in common fairness we ought to be excused from the payment of postage. The tax of postage, has of late become so exceedingly burdensome, that we have been compelled, in our own defence, to resolve that no letters in future shall be taken from the postman, unless they are postage free. The amount of postage in one week for *unpaid* letters, has exceeded thirty shillings.—ED. L.

call your attention to the history of the case.

The gentleman from whose limb this tumour was extracted, had another tumour of rapid formation in the thigh about eleven years ago, when he was near twenty-seven years of age. The seat of the diseased structure was the anterior and inferior part of the thigh, and in the space of a few months it attained a very considerable size. This sudden increase induced him to apply for medical advice, and he consulted a surgeon who told him it was quite necessary that amputation of the limb should be resorted to. In compliance with the advice thus received, the patient, who lived in the country, came to London, and prepared himself for the operation. The surgeon was punctual to the time appointed for operating, but when he had made a thorough examination of the tumour, he found the disease to be of so malignant a character that he considered it best not to proceed with the operation. Accordingly he made his excuses to the patient, and represented to him that he was anxious, before any thing decisive was done in the matter, to have the benefit of further surgical advice, and the best opinions upon the expediency or non-expediency of amputating the limb. In consequence of this resolution some of the first medical men in the metropolis were called in to the consultation, and the patient was seen by Sir E. Home, Mr. Cline, Sir Astley Cooper, and Mr. Abernethy, all of whom, looking upon it as a case of malignant fungus hæmatodes, expressed themselves against the operation, saying there was not the slightest chance of success. After this the gentleman returned to his residence, and upon viewing the various bearings of the matter, it seemed to him that he was sent back into the country to die. Under this feeling he thought whether he might not derive some assistance or consolation from additional advice, and he determined to take the opinions of two other surgeons. He saw a very experienced surgeon, who had not been of the former number, and myself. We visited the patient together, and that was the first occasion upon which I witnessed the state of the patient. At that time there was a tumour, about the size of the palm of my hand, situated just above the knee, and this had a soft feel and a red colour, having attained its magnitude in the space of two months. Besides this tumour, there was one over the eyebrow on the right side, there was another on the back of the pelvis, and a third situated in the lumbar region. There were also to be felt beneath the skin numberless little lumps, as if there had been scattered under it a quantity of heads of nails or split beans, in fact upon stroking your hand over the surface of the body you experienced that pe-

culiar feeling, which has been described by Mr. Abernethy as an indication of what he has called "*tuberculated sarcoma*." The patient was in a very emaciated condition, and experienced pain of a most acute character.

Upon the treatment to be adopted it happened that the other surgeon and myself did not agree. When I considered the malignant character of the complaint, the way in which it seemed to prevail throughout the frame, and when I reflected on the likelihood that the *internal* organs participated in the disorder, which is found to be the case in the majority of instances, I was led to give up all hopes of a favourable termination. The gentleman who was consulted with me was older than myself, and as we differed in our opinions, we sent them in separately, desiring the patient to consider well the subject, and wishing to hear further from him. He did consider the subject, and the result of his deliberation was, that he sent for the surgeon who had recommended amputation, and had the limb removed by him very high up. He recovered; he was soon released from the urgent symptoms, pain and loss of appetite, and was rapidly relieved in consequence, so that in the end he regained his health. In a few years after, however, the tumour over the eyebrow became very troublesome, and on the increase of the evil it was removed, and at the same time a part of the supra-orbital nerve was cut out together with the tumour.

In the month of December, 1828, the patient had one on his forearm which speedily increased, and was attended by attacks of excessive pain, extending above and below the tumour, and to such a degree that it became almost unbearable. Upon removal I found that the disease was connected with the branch of the nerve which ramifies over the back of the hand.

About six weeks since his attention was first called to the existence of the tumour which you now see on the plate. He had not been aware of the growth of this till he experienced repeated violent and lancinating pains. It was obvious that the plan to adopt was to operate, and accordingly I extirpated it last Saturday. In the removing of the tumour it appeared to be continued upwards towards the tuberosity of the ischium. I found, on cutting into the structure, an oval circumscribed substance which had the feel of cartilage, and presented the character of schirrus, resembling that disease as it appears when it exists in the female breast. The part which was continued to the tuberosity of the ischium, was only indurated, and was the portion which had been left after the former operation. Here you see that having no connexion with the muscular fibres, the tumour seems to be

altogether a new growth,—the deposition of something which did not originally enter into the composition of the part. The case is very interesting in a practical point of view, as it may serve to show us that we must not look upon all the morbid growths which occur in many parts of the body, as too malignant to render our interference of any avail; they are not always to be regarded in that light, since it is evident from the facts stated, that life may be prolonged for a considerable number of years. In the individual before mentioned, we see that the affection has already existed eleven years; and from the support already given to this patient, we may be led not to determine that, because the disease is of a malignant nature, the case is therefore hopeless, and nothing can be done for its relief.

In our report of the case of *Hernia* in the last Number, we promised to relate its progress and termination. The man died during the night of Wednesday, and on coming to the hospital about eleven o'clock on Thursday, we were surprised to learn that the post-mortem examination had been already concluded. The reasons for this haste we do not exactly comprehend, but, if we recollect rightly, the prospectuses for the school announce, "Morbid inspections, as opportunities occur, at one o'clock." Poor pupils!

During the short period that elapsed between the date of our last report and the patient's decease, nothing occurred particularly worthy of notice; the usual treatment was adopted.

Tuesday, December 14th.

#### SYPHILITIC IRITIS.

John Callan, *ætat.* 21, was admitted into Luke's Ward on the 22d of November, under the care of Mr. Vincent.

The vessels of the conjunctiva and sclerotics were minutely injected, those of the sclerotics exhibiting the usual pink colour; the cornea was hazy, the iris was of a dark-brown colour, puckered, thickened, and red vessels were seen on its anterior surface. The pupil was dilated rather more than is natural in a sound eye, retaining its central position, and its margin was but slightly irregular. Towards the external canthus, a tubercle of brownish yellow lymph was seen on the pupillary margin of the iris. In this situation the iris was connected to the capsule of the lens by a pretty thick band of lymph, which appeared organized. Vision was very imperfect. There was not much intolerance of light, and during the day his eye was tolerably free from pain. At night he was unable to sleep, in consequence of very severe pain in the eyebrow, and lan-

cinating pain, which extended through the orbit towards the brain. There was a scaly eruption of a pale copper hue over the chest and arms. Bowels constipated; tongue white; pulse full and strong.

He states that he has had a bad eye a week, but has done nothing for it; he had a chancre three months since, which healed under the influence of mercury; the sound iris is of a dark-grey colour.

Ordered to have  $\text{℥xiv}$  of blood taken from his arm; to take an active dose of calomel and jalap, and after the bowels have been well opened, to take a grain of emetic tartar every second hour in an ounce of cinnamon water. Apply the ext. belladonna to the brow every night.

23. He experienced no relief from the bleeding; his bowels were freely purged; the antimony produced no sickness or nausea; the eye appears precisely the same. The belladonna was applied, but the pupil is not more dilated than yesterday. Continue the ant. tart. and belladonna.

24. The inflammation of the conjunctiva is much less; he suffers rather more pain at night in the brow; he has not slept by night since his admission; bowels open; tongue clean; pulse rather full. To continue the emetic tart., and take three grains of calomel and a quarter of a grain of opium every four hours.

25. After our visit yesterday the eye became very painful, and the vascularity of the conjunctiva was very much increased. The house-surgeon, Mr. Wyatt, very judiciously bled him to  $\text{℥xx}$ , and ordered twelve leeches to be applied as close to the eye as possible. The patient says he experienced very great relief from the V.S., and slept well all night. There is not much inflammation of the conjunctiva or sclerotics, and the red vessels cannot now be seen in the iris. He says he feels perfectly easy. Continue cal. and opium.

26. Had no pain in the eye, and slept well all last night; about half the lymph that was observed on the iris is absorbed; cornea is much clearer; the belladonna has been applied every night, but the pupil is not more dilated than it was on his admission; mouth slightly sore. Continue ext. belladonna, and take the calomel and opium every six hours.

28. The eye is much better; very little vascularity remains; the tubercle of lymph has been absorbed; the pupil is more dilated, and the band of lymph which restrained the motions of the iris appears elongated, attenuated, and transparent. The cornea is perfectly transparent, and his vision is nearly restored; mouth not much sorer. Continue the belladonna, and the calomel and opium.

Dec. 1. The eye appears perfectly well,

and vision is improving fast. The pupil is now very much dilated; the adhesion is absorbed; the iris has assumed its natural colour; the eruption on the skin has disappeared; mouth very little sore. Continue the calomel and opium, and belladonna.

### HOTEL-DIEU.

#### FIBRO-CELLULAR TUMOUR OF THE NECK.

C—, ætat. 12, of a good constitution, was admitted at the end of October; he had from his infancy been affected with a tumour of the neck, which had eventually attained the size of a child's head; it occupied the left side of the neck, was of great consistence, though free from pain, and seemed to be attached by a pedicle. The pulsations of the carotid were distinctly felt behind, as also were those of the upper and lower thyroid arteries above and below, the tumour; the integuments were not discoloured; the veins were much enlarged, and one of them in particular, which was enormously distended, ran over the tumour in an oblique direction, from below upwards, and from the outer, towards the inner side, so that it would have been impossible to make any incision into the tumour without dividing this vein. M. Dupuytren hesitated whether he should perform the extirpation of the tumour. He recollected the case of a young female, on whom the extirpation of a similar tumour was performed, and who died during the operation, apparently from the introduction of air into the larger veins, and into the heart, an occurrence which has also been observed by MM. Graefe and Clemot, of Rochefort. However, as the gradual increase of the tumour seemed inevitably to lead to a fatal termination, he at last decided in favour of the removal, the assistants being ordered carefully to compress the larger veins which might be opened. The operation was performed on the 22nd of November in the following manner:—An assistant having raised the tumour as much as possible by pressing on its sides, a longitudinal incision was made through the skin and platysma myoides, and the tumour thus laid bare in its whole length; it was then dissected off, until completely isolated, from the surrounding parts, and adhering only by its pedicle, which, however, contrary to expectation, was found so large, that the idea of dividing it must be entirely abandoned. An incision was accordingly made into the mass of the tumour, in order to evacuate the fluid which M. Dupuytren thought he felt within it. This proved, however, to be a deception, for a small quantity of blood only issued from the wound. Under these cir-

cumstances, the only method of terminating the operation appeared to consist in the application of the ligature; this was accordingly resorted to, but it was not before three ligatures had been placed round the pedicle, that the hæmorrhage, particularly that from the veins, was arrested. About three pints of blood were lost during the operation. The patient had a slight fit of syncope, from which, however, he soon recovered, by the aspersion of cold water. In the course of the day he was taken with sickness and vomited repeatedly. Towards the evening this symptom disappeared, and he seemed to be pretty well till near morning, when he was suddenly seized with convulsions, and died, eighteen hours after the operation.

On examination, the tumour was found to be of fibro cellular texture. It originated from the left part of the thyroid gland, and had strongly pressed on the trachea, which had in consequence become flattened. The carotid, jugular veins, and thyroid arteries, had not been wounded during the operation.—*Lanc. Franç.*

#### MALFORMATION OF THE EAR.

A female, 36 years of age, of a good constitution, and mother of four children, fell during the sixth month of her fifth pregnancy, and struck the abdomen on the edge of a tub; she experienced a violent pain in the abdomen, and the movements of the child became much less than before. After about a fortnight they became as strong as before. In November, 1827, she was delivered of a child, which was regularly formed with the exception of the left ear, the helix of which was pushed anteriorly, and had in its middle a deep incision, which also traversed the antihelix and tragus, and continued over the cheek towards the nose, where it terminated. The meatus externus was obliterated; behind the ear there were four lenticular depressions. In 1829 the child was in good health, and heard quite well with the right, but not with the left ear.—*Zeitschr. d. Geburtskunde.*

#### LITERARY INTELLIGENCE.

Mr. JOHN SMITH, Lecturer on Anatomy and Surgery, is preparing for publication, *Practical Observations on the Nature, Cure, and Prevention of Consumption*, in its developed and incipient forms; wherein Counter-irritation (with the manner how, when, and the region to which such a remedial agent is practicable, safe, and efficacious), Inhalation of various Substances, and Climate, will be carefully examined.
